10. The combination of the pump, its crank-case, the pump-valves at one side of the cylinder, the compressed-air reservoir, a relief-valve chamber directly communicating with the pump, a port or passage leading from said relief-valve chamber to the crank-case, a relief-valve in said chamber, a governor-valve chamber beside the relief-valve chamber, ports connecting the governor-valve chamber with opposite ends of the relief-valve chamber, and ports leading from the governor-valve chamber to the atmosphere, a slide-valve in the governor-valve chamber, controlling all ports thereof; a piston in said governor-valve chamber actuating said slide-valve, a spring for holding the piston against the air-pressure, and an air-passage leading from the reservoir to the governor-valve chamber above the piston, all substantially as and for the purpose set forth.

707,688. CONVEYING APPARATUS. JOHN W. FOREMAN, Healdsburg, Cal. Filed Jan. 23, 1902. Serial No. 91,561. (No model.)

Claim.—1. A conveying apparatus including, in combination, a rigid track; standards upon which said track may be supported; a carriage adapted to travel upon said track; a grip comprising pivoted members having arm extensions; a pivoted yoke engaging said extensions and holding the grip members closed; a fall-block engaged by said grip; and a stop in the path of the yoke for actuating the grip to release the fall-block at a predetermined point along the track.

2. The combination in a conveying apparatus of an inclined trackway, and supports therefor; a carriage; a grip comprising opposing members pivoted to the carriage and having radial arm extensions; a yoke pivoted between its ends and engaging said radial extensions, to hold the grip members closed; a fall-line having one end secured to the carriage; a burden-carrier to be raised and lowered by the fall-line and to be engaged by the grip members; and means by which the yoke is moved about its pivotal connection whereby the members of the grip may be automatically opened at a predetermined point along said trackway.

3. The combination in a conveying apparatus of a trackway; a carriage; means for advancing the same along the trackway; a grip on the carriage and including opposing pivoted members having radial arm extensions; a horizontal holding member for said extensions said member pivotally mounted; a burden-carrier to be engaged by said grip members; and a means for automatically tripping said member and causing it to open the grip members at a point along the trackway.

4. The combination in a conveying apparatus, of a track, a carriage thereon, gripping members pivoted on said carriage, arm extensions on said members, a pivoted yoke connecting with said extensions, trippers on the track extending into the path of said yoke by which the grip members are opened and a fall-line and a fall-block in connection with said carriage.

5. The combination in a conveying apparatus, of a track, a carriage thereon, gripping members pivoted on said carriage, divergent arm extensions on said members, a yoke pivoted intermediate of said members and engaging the ends of said arms, trippers disposed on opposite sides of the track adjacent to the points of loading and unloading, said trippers extending into the path of the yoke by which the grip members are opened, and a fall-line and a fall-block in connection with the carriage.

6. The combination in a conveying apparatus of a track, a carriage thereon, grip members pivoted on the carriage, arms on said members by which the latter are moved to open, other arms or extensions rigid with said members and means thereon for engaging a fixed support to hold the carriage stationary and a fall-line and fall-block or burden-carrier in connection with said carriage.

7. In a conveying apparatus, the combination of a track, a carriage having pivoted grip members thereon, arms on said members, a yoke connecting said arms whereby they may be moved simultaneously to open the jaws, means in the path of the yoke for tripping the same, and a cable and fall in connection with said carriage.

8. In a conveying apparatus, the combination of a track, a carriage having grip members pivoted thereon, arms on said members, a yoke or bar pivotally connected to each of said arms, and trippers having fixed points of supports adapted to extend into the path of said bar whereby the latter may be oscillated and the grip members opened.

9. In a conveying apparatus, the combination of a track, a carriage, grip members pivoted thereon, arms on said grip members and means including an oscillating member and a trip device in the path thereof by which said members may be automatically operated to open the jaws.

10. In a conveying apparatus the combination of a carriage having a longitudinal slot; a grip including opposing pivoted members having horizontal and vertical arm extensions lying within said slot; a yoke upon the carriage and engaging said vertical extensions; means for tripping the yoke to release the extensions; a fall line and block attached to the carriage; and means carried by the block to be engaged by the grip members.

11. In a conveying apparatus, a fall-block having a rigid bail secured thereto, and means upon said block consisting of a point of attachment at one side of the fall-block and a guide at the opposite side of the fall-block whereby said bail is made always to stand vertical when the block is suspended upon the portion of the line or cable between said point of attachment and guide.

12. In a conveying apparatus, the combination with the track and a carriage thereof, of a fall-block, having a rigid bail, said bail including a horizontal portion essentially triangular in cross-section and adapted to engage grip members on said carriage and a line or cable secured to said carriage at one side of the fall-block and a guide-pulley at the other side of the fall-block said line or cable passing through said block and over said pulley by which the block is raised and lowered and the carriage moved along the track.

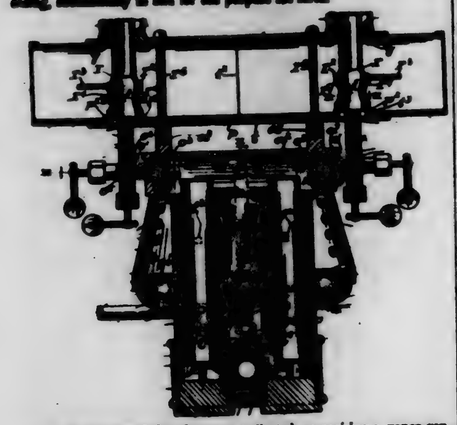
13. In a conveying apparatus, a carriage having a longitudinal slot, grip members pivoted therein, vertical and horizontal arm extensions on each of said members, a yoke connecting said vertical arms, and projections upon said horizontal arms.

14. In a conveying apparatus, the combination with a track of a wheeled carriage thereon, having a longitudinal slot-opening, jaws pivoted therein, arms upon said jaws, a yoke pivotally connected with each arm, trippers having a fixed point of support, each of said trippers including a pivoted arm adapted to have one arm extend into the path of the yoke and to engage and oscillate the yoke to open the jaws when the carriage moves in one direction and said trip-arm adapted to allow the yoke to pass without disturbing the jaws when the carriage moves in the other direction.

15. In a conveying apparatus, the combination with a track, of a carriage having a longitudinal slot-opening, jaws pivoted therein, vertical and horizontal arm extensions on each of said members, means by which the latter are normally kept closed, means connected with the vertical arms whereby the jaws are moved in unison, tripping devices upon the track whereby the movement of said jaws is automatically effected, a fall-line attached to the carriage, a fall-block adapted to be raised and lowered by said line, and means upon the track engaging said horizontal-arm extensions whereby the carriage may be held stationary.

707,689. VAPOR-GENERATING APPARATUS FOR HYDROCARBON-BURNERS. THOMAS J. FORDE, Geneva, Ohio. Filed Apr. 11, 1901. Serial No. 55,284. (No model.)

Claim.—1. Apparatus of the character indicated, comprising a vapor-generator having an oil-inlet at the lower end and a vapor-outlet at its upper end, means for supplying oil to the said oil-inlet, a generator-heater arranged between the upper and lower ends of the generator and provided with a vapor-inlet, a pipe-line for supplying oil-vapor-laden air to the generator-heater, and a valve-casing having the following: an upper tubular vapor-receiving member in open relation with the aforesaid vapor-outlet of the generator and extending laterally of the generator outwardly from the said vapor-outlet, a lower tubular vapor-discharging member arranged to discharge into the vapor-inlet of the generator-heater, an upright tubular member having the passage-way therethrough connecting the passage-ways formed in the aforesaid vapor-receiving member and vapor-discharging member of the valve-casing, a valve for interrupting and for establishing a flow of vapor from the generator through the said valve-casing, a tubular member having the passage-way formed therein connected with the passage-way of the aforesaid vapor-discharging member of the valve-casing and connected and in open relation with the aforesaid pipe-line, a needle-valve for regulating the discharge of vapor from the vapor-discharging member of the valve-casing, and a valve for establishing and for interrupting the flow of vapor-laden air from the said pipe-line to the said vapor-discharging member of the valve-casing, substantially as and for the purpose set forth.



2. Apparatus of the character indicated, comprising a vapor-generator having an oil-inlet at the lower end and a vapor-outlet at its upper end, means for supplying oil to the said oil-inlet, a generator-heater arranged between the upper and lower ends of the generator and provided with a vapor-inlet, a pipe-line for supplying oil-vapor-laden air to the generator-heater, and a valve-casing having the following: an upper tubular vapor-receiving member in open relation with the aforesaid vapor-outlet of the generator and extending laterally of the generator outwardly from the said vapor-outlet, a lower tubular vapor-discharging member arranged to discharge into the vapor-inlet of the generator-heater, an upright tubular member having the passage-way therethrough connecting the passage-ways formed in the aforesaid vapor-receiving member and vapor-discharging member of the valve-casing, a valve for interrupting and for establishing the flow of vapor from the generator through the valve-casing, a tubular member depending from the aforesaid vapor-discharging member of the valve-casing and having the passage-way formed therein connected with the passage-way of the said vapor-discharging valve-casing member, which depending valve-casing member has a laterally-projecting tubular arm connected and in open relation with the aforesaid pipe-line, a needle-valve for regulating the discharge of vapor from the vapor-discharging member of the valve-casing and another valve for establishing and for interrupting the flow of vapor-laden air from the said pipe-line into the said vapor-discharging member of the valve-casing, substantially as and for the purpose set forth.

3. Apparatus of the character indicated, comprising a vapor-generator having an oil-inlet at the lower end and a vapor-outlet at its upper end, means for supplying oil to the said oil-inlet, a generator-heater arranged between the upper and lower ends of the generator and provided with a vapor-inlet, a pipe-line for supplying oil-vapor-laden air to the generator-heater, and a valve-casing having the following: an upper tubular vapor-receiving member arranged to receive vapor from the aforesaid vapor-outlet of the generator and extending laterally of the generator outwardly from the said vapor-outlet, stub-valve within the said vapor-receiving member of the valve-casing, a lower tubular vapor-discharging member arranged to discharge into the vapor-inlet of the generator-heater, a needle-valve within the said vapor-discharging member of the valve-casing, an upright tubular member having the passage-way therethrough connecting the passage-ways formed in the aforesaid vapor-receiving member and vapor-discharging member of the valve-casing, a tubular member depending from the said vapor-discharging member and having the passage-way formed therein connected with the passage-way in the said vapor-discharging member, which depending member has a laterally-projecting tubular arm connected with and in open relation with the aforesaid pipe-line, and a stub-valve within the said depending member, substantially as and for the purpose specified.

4. The combination, with a vapor-generator comprising a chambered bottom section having an oil-inlet, a chambered top section having vapor-outlets, and an upright tubular central section establishing open relation between the chamber of the bottom section and the chamber of the top section, and means for supplying oil to the aforesaid inlet, of a generator-heater comprising a coil extending around the central section of the generator and provided with perforations arranged to discharge against the said central section, which coil has a vapor-inlet; a shelf bearing the said coil and having air-supply perforations, and means for controlling and regulating the supply of vapor from one of the aforesaid vapor-outlets of the generator to the vapor-inlet of the said coil, substantially as and for the purpose set forth.

5. The combination, with a vapor-generator comprising a chambered bottom section having an oil-inlet, a chambered top section having vapor-outlets, and an upright tubular central section establishing open relation between the chamber of the bottom section and the chamber of the top section, and means for supplying oil to the aforesaid oil-inlet, of a generator-heater comprising a coil which is provided, at the top, with perforations arranged to discharge against the said central section, and has a vapor-inlet; a shelf bearing the said coil and having air-supply perforations, which shelf is provided with an upwardly-projecting flange extending around the coil, and means for controlling and regulating the supply of vapor from one of the aforesaid vapor-outlets of the generator to the vapor-inlet of the said coil, substantially as shown, for the purpose specified.

6. The combination, with a vapor-generator comprising a chambered bottom section having an oil-inlet, a chambered top section having vapor-outlets, and an upright tubular central section establishing open relation between the chamber of the bottom section and the chamber of the top section, and means for supplying oil to the aforesaid oil-inlet, of a generator-heater comprising a coil extending around the central section of the generator and provided, at the top, with perforations arranged to discharge against the said central section, which coil has a vapor-inlet; means for controlling and regulating the supply of vapor from one of the aforesaid vapor-outlets of the generator to the vapor-inlet of the said coil; a shelf bearing the said coil and supported from the generator, which shelf has air-supply perforations, and a guard-forming laterally-perforated casing extending around the central section of the generator between the top section of the generator and the said shelf and secured to the said shelf, substantially as and for the purpose set forth.

7. The combination, with a vapor-generator comprising a chambered bottom section having an oil-inlet, a chambered top section having vapor outlets, and an upright tubular central section establishing open relation between the chamber of the bottom section and the chamber of the top section, and means for supplying oil to the aforesaid oil-inlet, of the generator-heater comprising a coil extending around the central section of the generator, and provided, at the top, with perforations arranged to discharge against the said central section, which coil has a vapor-inlet; means for controlling and regulating the supply of vapor from one of the aforesaid vapor-outlets of the generator to the vapor-inlet of the said coil, a shelf bearing the said coil and extending around and supported from the central section of the generator, which shelf has air-supply perforations and a surrounding upwardly-projecting flange, and a guard-forming laterally-perforated casing extending around the central section of the generator and secured to the said flange, substantially as and for the purpose set forth.

8. The combination, with a vapor-generator comprising a bottom section having an oil-inlet, a chambered top section having vapor-outlets and an external laterally-projecting flange and an upright tubular central section establishing open relation between the chamber of the bottom section and the chamber of the top section, and means for supplying oil to the aforesaid oil-inlet, of a generator-heater comprising a coil extending around the central section of the generator, and provided, at the top, with perforations arranged to discharge against the said central section, which coil has a vapor-inlet; means for controlling and regulating the supply of vapor from one of the aforesaid vapor-outlets of the generator to the vapor-inlet of the said coil and extending around and supported from the central section of the generator, a shelf bearing the said coil and having air-supply perforations, and a guard-forming laterally-perforated casing surrounding the central section of the generator and extending from the aforesaid flange of the top section of the generator to the said shelf and attached to the shelf, substantially as and for the purpose set forth.

9. The combination, with a vapor-generator comprising a chambered bottom section having an oil-inlet, a chambered top section having vapor-outlets, and an upright tubular central section establishing open relation between the chamber of the bottom section and the chamber of the top section, and means for supplying oil to the aforesaid oil-inlet, of a generator-heater comprising a coil surrounding the central section of the generator, and provided, at the top, with perforations arranged to discharge against the said central section, which coil has a vapor-inlet; means for controlling and regulating the supply of vapor from one of the aforesaid vapor-outlets of the generator to the vapor-inlet of the said coil; a shelf bearing the said coil and adjustable vertically, and means for securing the said shelf in the desired adjustment to the central section of the generator, substantially as and for the purpose set forth.

10. Apparatus of the character indicated, comprising a vapor-generator having a chambered top section provided with vapor-outlets, an upright tubular central section in open relation at its upper end, with the chamber of the top section, and a chambered bottom section having its chamber in open relation with the lower end of the central section and provided with an oil-inlet, which bottom section has the lower wall of its chamber provided with an aperture in registry with the central section of the generator, a removable plug closing the said aperture, a drum arranged internally and centrally of the central section of the generator and extending from within the bottom section to within the top section of the generator, means for holding the said drum centrally of the central generator-section, means for holding the drum elevated above the lower wall of the bottom section of the generator, the generator-heater having a vapor-inlet, and means for controlling and regulating the supply of vapor from one of the aforesaid vapor-outlets of the generator to the vapor-inlet of the generator-heater and the aforesaid plugged aperture being large enough to accommodate the introduction into, or removal from, the central generator-section, of the aforesaid drum.

11. Apparatus of the character indicated, comprising a vapor-generator having a chambered bottom section provided with an oil-inlet, a chambered top section having vapor-outlets, and pipes arranged a suitable distance apart laterally and establishing open relation between the chamber of the bottom section and the chamber of the top section, a generator-heater comprising a coil extending around the aforesaid pipes and having perforations arranged to discharge against the said pipes and provided with a vapor-inlet, and means for controlling and regulating the supply of vapor from one of the aforesaid vapor-outlets of the generator to the vapor-inlet of the said coil.

12. Apparatus of the character indicated, comprising a vapor-generator having a chambered bottom section provided with an oil-inlet, a chambered top section having vapor-outlets, and upright pipes arranged a suitable distance apart laterally and establishing open relation between the chamber of the bottom section and the chamber of the top section, a generator-heater comprising a coil extending around the said pipes and closed at one end and having a vapor-inlet at its other end, which coil is provided, at the top, with perforations arranged to discharge against the said pipes, and means for controlling and regulating the supply of vapor from one of the aforesaid vapor-outlets of the generator to the vapor-inlet of the said coil.

13. Apparatus of the character indicated, comprising a vapor-generator having a chambered bottom section provided with an oil-inlet, a chambered top section having vapor-outlets, and two upright pipes arranged a suitable distance apart laterally and establishing open relation between the chamber of the bottom section and the chamber of the top section, a generator-heater comprising an S-shaped coil surrounding both of the said pipes and extending between the pipes and provided, at the top, with perforations arranged to discharge against the said pipes, which coil is closed at one end and has its other end terminating in a vapor-inlet, and means for controlling and regulating the supply of vapor from one of the aforesaid vapor-outlets of the generator to the vapor-inlet of the said coil.

14. Apparatus of the character indicated, comprising a vapor-generator having a chambered bottom section provided with an oil-inlet, a chambered top section having vapor-outlets, and two upright pipes arranged a suitable distance apart laterally and establishing open relation between the chamber of the bottom section and the chamber of the top section, a generator-heater comprising an S-shaped coil surrounding both of the aforesaid pipes and extending between the pipes and provided, at the top and at suitable intervals longitudinally of the coil, with perforations arranged to discharge against the said pipes, which coil is closed at one end and has its other end forming a vapor-inlet means for controlling and regulating the supply of vapor from one of the aforesaid vapor-outlets of the generator to the vapor-inlet of the said coil, a shelf instrumental in supporting the coil and secured to both of the aforesaid pipes, which shelf has air-supply perforations, and a laterally-perforated guard-forming casing extending around the generator next above and attached to the said shelf, substantially as and for the purpose set forth.

15. In apparatus of the character indicated, a vapor-generator having its upper end provided with a vapor-outlet, a saddle elevated above the generator so as to form an air-space between it and the top of the generator, an air-receiving casing arranged in a horizontal plane and seated on the aforesaid saddle, an upwardly-extending service-pipe, an upright tube arranged to discharge into the said service-pipe and having an air-inlet arranged to receive air from within the air-receiving casing, and a valve-casing interposed between the aforesaid vapor-outlet of the generator and the lower end of the said tube and having valved passage-ways for controlling and regulating the passage of vapor from the generator to the said tube.

16. In apparatus of the character indicated, a vapor-generator provided with a chambered vapor-receiving top section having two lateral vapor-outlets arranged diametrically opposite each other; upwardly-projecting lugs formed upon the said top section; a saddle mounted on the said lugs, an air-receiving casing arranged in a horizontal plane and mounted on the said saddle; two upwardly-extending service-pipes arranged a suitable distance apart longitudinally of the top of the said casing; two upright tubes arranged to discharge upwardly into the different service-pipes, respectively, and extending approximately through the aforesaid air-receiving casing and provided, respectively, with a lateral air-inlet, and two valve-casings interposed between the different vapor-outlets, respectively, of the generator and the lower end of the different aforesaid tubes, respectively, and having valved passage-ways for controlling and regulating the passage of vapor from the generator to the said tubes.

17. In apparatus of the character indicated, a vapor-generator having two vapor-outlets arranged a suitable distance apart; an air-receiving casing arranged in a horizontal plane and supported above the generator; two upwardly-extending service-pipes arranged a suitable distance apart longitudinally of the top of the said casing; two upright tubes arranged to discharge upwardly into the different service-pipes, respectively, and extending approximately through the aforesaid air-receiving casing and provided, respectively, with lateral holes or apertures; two sleeves movably mounted upon the different aforesaid tubes, respectively, and having lateral holes or apertures arranged to render them capable of registering with the lateral holes or apertures of the respective tubes, and two valve-casings interposed between the aforesaid vapor-outlets of the generator and the lower end of the different aforesaid tubes, respectively, and having valved passage-ways for controlling and regulating the passage of vapor from the generator to the said tubes, substantially as and for the purpose set forth.

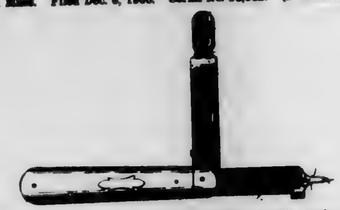
18. In apparatus of the character indicated, a vapor-generator provided with a chambered vapor-receiving top section having two lateral vapor-outlets arranged a suitable distance apart; two upwardly-projecting lugs formed upon the said top section and arranged a suitable distance apart; a saddle mounted on the said lugs and having two apertures arranged a suitable distance apart and upwardly-projecting flanges extending about the apertures; an air-receiving casing arranged in a horizontal plane and seated on the saddle and perforated at the bottom to accommodate the location of the aforesaid flanges; two upwardly-extending service-pipes arranged above the said casing over the different saddle-apertures, respectively; two upright tubes arranged to discharge upwardly into the different service-pipes, respectively, and extending into the different saddle-apertures, respectively, and provided, respectively, with a lateral air-inlet, and two valve-casings interposed between the different vapor-outlets, respectively, of the top section of the generator and the lower end of the different aforesaid tubes, respectively, and having valved passage-ways for controlling and regulating the passage of vapor from the generator to the said tubes, substantially as and for the purpose set forth.

19. In apparatus of the character indicated, a vapor-generator provided, at its upper end, with two vapor-outlets arranged a suitable distance apart; upwardly-projecting lugs formed upon the upper end of the generator, a saddle mounted upon the said lugs; an air-receiving casing arranged in a horizontal plane and composed of two tubular sections arranged end to end and seated in the aforesaid saddle; a top plate extending over and resting upon both of the said sections; bolts or screws extending through the said top plate into the aforesaid lugs; two upwardly-extending service-pipes arranged above and a suitable distance apart longitudinally of the said casing; two upright tubes arranged to discharge upwardly into the different service-pipes, respectively, and extending approximately through the said casing, and provided, respectively, with an air-inlet in open relation with the chamber of the aforesaid casing, and two valve-casings interposed between the different vapor-outlets, respectively, of the generator and the lower end of the different aforesaid tubes, respectively, and having valved passage-ways for controlling and regulating the passage of vapor from the generator to the said tubes.

20. In apparatus of the character indicated, a vapor-generator provided, at its upper end, with a vapor-outlet; upwardly-projecting lugs

formed upon the upper end of the generator; a saddle mounted upon the said lugs; an air-receiving casing arranged in a horizontal plane and seated in the saddle; a layer of fireproof material, which is a good non-conductor of heat, covering the lower portion of the said casing; means for supplying oil to the generator; a generator heater extending around the generator; a service-pipe extending upwardly above the aforesaid air-receiving casing; an upright tube arranged to discharge upwardly into the service-pipe and extending approximately through the said air-receiving casing and provided with a lateral air-inlet in open relation with the chamber of the said casing, and a valve-casing interposed between the vapor-outlet of the generator and the lower end of the aforesaid tube and having valved passage-ways for controlling and regulating the passage of vapor from the generator to the said tube, substantially as and for the purpose set forth.

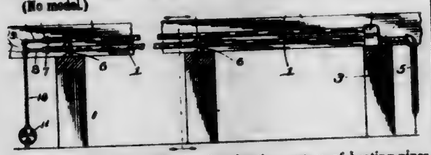
707,690. LOOM-FIXER'S KNIFE. CHARLES FOSTER, West Warren, Mass. Filed Dec. 6, 1900. Serial No. 38,962. (No model.)



Claim.—1. A loom-fixer's knife comprising a handle having a blade mounted therein and provided with a terminal awl-blade and a hook adjacent to the base of the awl-blade at one side of the blade of the knife, said hook lying in a plane beyond the side edge of the knife-blade, and projecting beyond the side face of the knife-blade, said hook being adapted for engagement with eyelet-screws to remove them.

2. A tool comprising a handle having blades pivoted therein upon a common pivot and adapted to open to aline with the handle, one of said blades having a terminal punching-gouge and the other blade having no sharp side edges whereby it may be grasped in connection with the handle to rotate the punching-blade, the punching-blade being longer than the other blade so that it may be employed for punching when both blades are open to the same degree.

707,691. HEATING APPARATUS. EDWARD GERRARD, Indianapolis, Ind., assignor to the National Dry Kiln Company, Indianapolis, Ind., a Corporation of Indiana. Filed Apr. 3, 1901. Serial No. 54,110. (No model.)

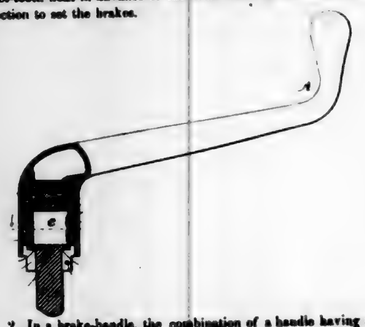


Claim.—1. The combination, in a heating system, of heating-pipes of uniform length, a discharging-header at one end to which said pipes are connected, a steam-receiving header at the other end, small pipes leading from said header and running substantially at right angles to and communicating with the ends of said heating-pipes, elbows and couplings connected to the small pipes and the heating-pipes respectively, and right and left hand threaded nipples uniting said couplings and said elbows, substantially as and for the purposes set forth.

2. The combination, in a heating system, of a framework, a discharging-header for the pipes fixedly secured to said framework, two series of comparatively large heating-pipes connected to and held by said header and arranged in two horizontal planes; suitable supports for said heating-pipes on which they are loosely mounted, a steam-receiving header arranged in a different plane from that wherein said heating-pipes are positioned, and slender flexible pipes run in the same vertical plane connecting said header with said heating-pipes, substantially as and for the purposes set forth.

707,692. BRAKE-HANDLE. HOWARD W. GIBBS, Boston, Mass., assignor to William Hall & Co., Boston, Mass., a Firm. Filed June 20, 1902. Serial No. 112,546. (No model.)

Claim.—1. A brake-operating device comprising a handle having a cylindrical chamber at its inner end provided with vertical ratchet-teeth, a brake-staff having its upper end inclosed within said chamber and provided therein with a transverse slot extending diametrically therethrough, and a horizontally-sliding pawl fitted in said slot and adapted to be moved in opposite directions by the alternate contact of its opposite ends with the inclined faces of said ratchet-teeth, whereby one or the other of the ends of said pawl will be always projected into a position to engage the ratchet-tooth next in advance of the same when the handle is moved in a direction to set the brakes.

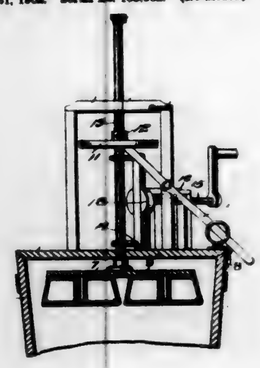


2. In a brake-handle, the combination of a handle having a cylindrical chamber at its inner end, the inner wall of which is provided with vertical ratchet-teeth, a brake-staff having its upper end inclosed within said chamber and provided therein with a transverse slot extending diametrically therethrough, and a horizontally-sliding pawl fitted within said slot and having its ends beveled on opposite sides, said ends being adapted to be alternately brought into contact with the inclined faces of said ratchet-teeth on the backward movement of the brake-handle, whereby when said handle is moved in a direction to set the brakes, one end or the other of said pawl will be projected laterally into a position to engage the first ratchet-tooth in advance of the same to bring the handle into locking engagement with the brake-staff, and means for holding together the said handle and brake-staff.

3. The combination of a brake-handle having a cylindrical chamber at its inner end and provided with ratchet-teeth, a brake-staff having its upper end inclosed within said chamber and provided therein with a transverse slot extending diametrically therethrough, a horizontally-sliding pawl fitted in said slot and adapted to be moved in opposite directions by the alternate contact of its opposite ends with the inclined faces of the ratchet-teeth on the inside of said chamber, and a vertically-divided nut embracing the brake-staff and screwed into the open end of the chamber in the handle to hold together said handle and brake-staff.

4. The combination of a handle having a cylindrical chamber at its inner end, a hard-metal bushing within the same provided with vertical ratchet-teeth, a brake-staff having at its upper end a portion of increased diameter inclosed within said chamber and provided with a transverse slot extending diametrically therethrough, a horizontally-sliding pawl fitted in said slot and adapted to be moved in opposite directions by the alternate contact of its opposite ends with the inclined faces of the ratchet-teeth, and a nut embracing the brake-staff beneath said enlarged portion and screwed into the open end of the chamber in the handle to hold together said handle and brake-staff.

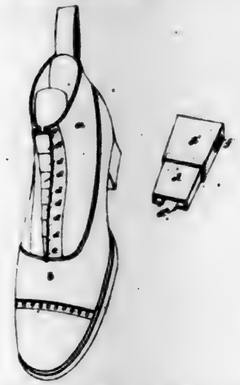
707,693. WASHING-MACHINE. JAMES G. GIBB, Nemaha, Iowa. Filed Apr. 21, 1902. Serial No. 103,962. (No model.)



Claim.—1. In a washing-machine, the combination with a receptacle having a cover, of a frame mounted thereon, a pounder or plunger having a rod guided on the frame, a disk mounted on the rod, a lever fulcrumed on the frame and arranged to engage the disk to hold the pounder or plunger elevated, a catch mounted on the cover and provided with resilient coils forming jaws for engaging the lever, and means for holding the lever out of engagement with the disk, substantially as described.

2. In a washing-machine, the combination with a receptacle, of a guide-frame, a pounder or plunger having a rod guided on the frame, a disk mounted on the rod, a lever fulcrumed on the guide-frame and arranged to engage the disk to hold the pounder or plunger elevated, and means for holding the lever in and out of engagement with the disk, substantially as described.

707,694. SHOE-FASTENER. JOHN F. HAWKES, Jersey City, N. J., assignor of one-half to Samuel Blatt, Jersey City, N. J. Filed Nov. 30, 1901. Serial No. 83,983. (No model.)



Claim.—1. A shoe provided along the edge of its opening with engaging means, combined with a fastening, the latter comprising a series of telescoping sections graduated in size and adapted at their opposite sides for engaging the said engaging means of the shoe.

2. A shoe provided along the edge of its opening with engaging means, combined with a fastener comprising a series of sections coupled together and graduated in size, whereby they are adapted to telescope, each of said sections being adapted to removably engage said engaging means of the shoe.

3. A fastener, comprising a series of sections graduated in size, whereby they are adapted to telescope one within the other, and means for preventing their separation, said sections being adapted at their opposite edges to engage removably with projections on a shoe and close the opening in the latter.

4. A shoe, the opening of which is provided with engaging means, combined with a fastener comprising a series of non-separable sections loosely coupled together, graduated in size and therefore adapted to telescope one within the other, and means for locking the said sections against telescoping.

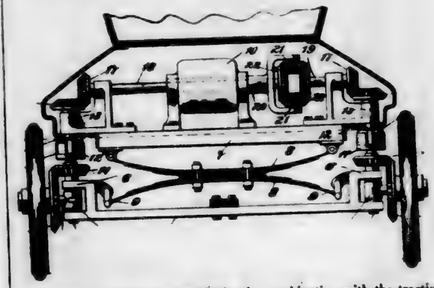
5. A shoe, the opening of which is provided with engaging means, combined with a fastener, comprising a series of non-separable loosely-coupled sections graduated in size, and therefore adapted to telescope one within the other, and means for securing the lowermost section to the lower end of the shoe-opening and for locking the fastener against telescoping.

6. A shoe, the opposite edges of the opening in which is provided with engaging means, combined with a fastener comprising a series of non-separable tapered graduated sections adapted to telescope one within the other, said sections being adapted to removably engage said engaging means of the shoe, and means for securing said fastener against telescoping.

7. A shoe provided along the opposite edges of its opening with the prong *a*, combined with the fastener, consisting of the series of tapered and graduated sections *d* loosely connected and adapted to telescope the one within the other, the rod *c* connected to the shoe-upper at the lower end of the opening and at its upper end to the lower section *d* of the series, and the upper section of the series being provided with the notches *f* and opposite side slots *f'*.

8. A shoe-fastener, consisting of a series of sections held in engagement with each other, each of which sections is provided with legs to form recesses in which prongs on the shoe may be held, and each of said sections being so formed that the sections immediately below it may be inserted into it, substantially as specified.

707,695. MOTOR-VEHICLE. JOSEPH H. HOADLEY, New York, N. Y., assignor to the Pneumatic Carriage Company, New York, N. Y., a Corporation of West Virginia. Filed Dec. 27, 1900. Serial No. 41,211. (No model.)



Claim.—1. In a motor-vehicle, the combination with the traction-wheels and their independent shafts, and the truck-frame to which said shafts are pivotally connected, of a vehicle-frame spring-supported on the truck-frame, a motor carried by said vehicle-frame, a shaft connected to said motor, shafts on the spring-supported vehicle-frame in line with the pivotal shafts for the traction-wheels, connections comprising bevel-gears from the motor-shaft to the other spring-supported shafts, extensible couplings between the last-named shafts and the pivotal shafts for the traction-wheels, and bevel-wheels on said pivotal shafts and on the traction-wheels, whereby the motor drives both traction-wheels while pivotal and vertical movements of the latter relative to the motor are permitted.

2. In a motor-vehicle, the combination with the traction-wheels and their independent shafts, and the truck-frame to which said shafts are pivotally connected, of a vehicle-frame spring-supported on the truck-frame, a motor carried by said vehicle-frame, a shaft connected to said motor, shafts on the spring-supported vehicle-frame in line with the pivotal shafts for the traction-wheels, connections comprising bevel-gears from the motor-shaft to the other spring-supported shafts, the connection to one of said shafts also comprising a compensating gear, extensible couplings between the last-named shafts and the pivotal shafts for the traction-wheels, and bevel-wheels on said pivotal shafts and on the traction-wheels, whereby the motor drives both traction-wheels while pivotal and vertical movements of the latter relative to the motor are permitted.

707,696. MAIL-CATCHER. CALEB E. P. HOBART, Meriden, Iowa. Filed Mar. 1, 1902. Serial No. 96,274. (No model.)

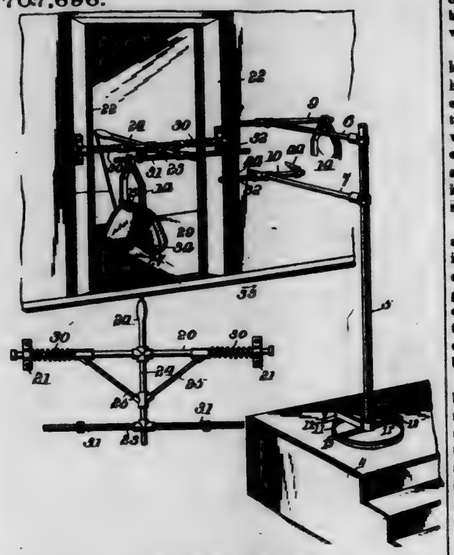
Claim.—1. In a mail-bag catcher, a bail in loop shape provided with a clamping-bar for holding the mail-bag.

2. In a mail-bag catcher, a loop-shaped bail fitted to hold a mail-bag and narrowed at its upper end and a spring projecting within the narrowed portion.

3. In a mail catcher and deliverer for exchanging mails at a railway-station through the medium of postal cars in transit the combination with a mail-bag holder or bail 33, loop-shaped and narrowed at the top, provided with a clamp for holding a mail-bag within, and having a protecting-spring in the narrow upper end for the purpose of engaging it with the catching and delivering rods when placed on them for use, of a shaft 20 journaled to rotate and to slide in bearings fixed to the postal-car doorway, a crane-bar 24 fixed to shaft 20 and to shaft 23 at its middle point, the crane-bar extending beyond rod 23 to aid in removing the mail from the crane, the other end of the crane-bar extending beyond shaft 20 for a handle for the use of the operator, and fixed or anchored to the floor or preferably to the ceiling over the door when in use, shaft 20 being provided also with protecting-springs at its ends to overcome the shock when removing the mail from the crane, and the catching-rod 23 being provided with protecting-collars on its ends for the purpose of holding the mail secure when deposited within the postal car.

4. In a vertical crane made to revolve in a platform, two arms and a locking-bar in line above each other, the locking-bar being just above the platform; arm 7 being provided with a receiving-rod 10, having protecting-collars at its ends, the arm extending beyond the receiving-rod a sufficient distance to aid in removing the mail from the catcher, provided with resisting cushions or springs, an arm 6 being located near the top of the vertical shaft having a delivering-rod 9, provided with regulating-collars near its ends.

707,696.



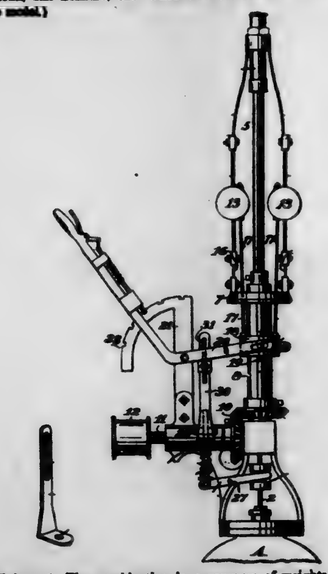
collar slidable upon and revolvable with the sleeve and in unison with the balls, rods connecting said collar with the balls, and a clutch-lever by which the collar and the balls may be moved up or down.

3. The combination in a governor of the spindle, valve-stem, revolvable sleeve, a collar slidable on and revolvable with said sleeve, guides having the lower ends flexibly connected with the sleeve, and the upper end with springs, balls slidable upon the guides having connections between them and the collar whereby they may be moved up or down to vary the leverage upon the fulcrumed guides and the consequent speed of the engine, a fulcrumed clutch-lever by which the sleeve is movable, a spring acting upon the governor-valve, and means intermediate between it and the lever whereby its tension is increased or diminished by the movement of the lever.

4. The combination in a governor of a vertical hollow spindle a valve-stem turnable therein, a sleeve turnable upon the spindle, rigid guides having their lower ends flexibly connected with the sleeve, and the upper ends with the upper end of the valve-stem, and springs by which the guides are normally drawn together, weights slidable upon the guides, a collar turnable with and slidable upon the sleeve, connections between the weights and collar, a lever by which the weights may be moved to or from the fulcrum-points of the guides, and a segment-rack and pawl by which any adjustment is retained.

5. The combination in a governor of weights capable of separation by centrifugal force, springs by which they are normally drawn together, rigid guides extending between the springs and a revolvable fulcrum connection between the weights and a collar slidable upon and revolvable with the governor-sleeve, a lever by which the collar and weights are movable, a supplemental spring and lever through which it acts upon the valve-stem, and a connection between said spring and the collar and weight-actuating lever, whereby the tension of the spring is changed, in unison with the movements of the weights.

707,697. VARIABLE-SPEED GOVERNOR. CHARLES A. HUFFMASTER, San Leandro, Cal. Filed Nov. 29, 1901. Serial No. 84,026. (No model.)



Claim.—1. The combination in a governor of weights capable of separation by centrifugal force, springs by which they are normally drawn together, guides extending between said springs and a revolvable fulcrum connections between the weights and a slidable revolvable collar upon the governor-sleeve, and means whereby the weights may be moved up or down upon the guides.

2. A governor consisting of a stationary hollow spindle, a valve-stem extending therethrough, a revolvable cap at the top of the spindle within which the upper end of the valve-stem terminates, a sleeve revolvable upon the spindle, guides having the lower ends flexibly connected with a disk carried by the sleeve, springs connecting the upper ends of the guides with the revolvable cap, weights slidable upon the guides, a

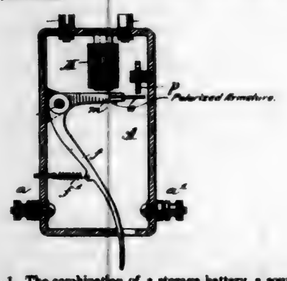
---

707,698. MANUFACTURE OF CHEESE. FREDERICK A. HUEB, Cookshire, Canada, assignor to Charles Cleveland Bailey, Cookshire, Canada. Filed Dec. 16, 1901. Serial No. 86,078. (No specimens.)

Claim.—1. The process of making cheese which consists in mixing buttermilk churned from sour cream with sweet fresh skimmed milk to precipitate curd, draining the curd and exposing the strained curd to the atmosphere until it assumes a cheese flavor, then slightly pressing the same, drying a sufficient time to solidify the mass, then disintegrating the same, and finally re-pressing the cheese, substantially as set forth.

2. The process of making skim-milk cheese which consists in precipitating curd by mixing sour buttermilk and sweet fresh skim-milk, drawing off the whey and draining the curd, aerating the strained curd, and salting to taste, then lightly pressing the aerated curd to remove whey and solidifying it by drying, then disintegrating the cured cheese and firmly re-pressing the same for market, substantially as set forth.

707,699. CHARGING-SWITCH. MILLER R. HUTCHISON, New York, N. Y., assignor, by mesne assignments, to Hutchison Acoustic Company, a Corporation of New Jersey. Filed Nov. 15, 1901. Serial No. 82,260. (No model.)



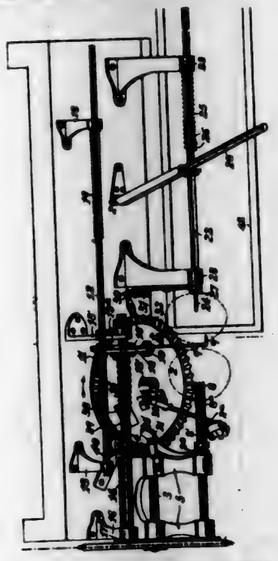
Claim.—1. The combination of a storage battery, a source of electricity, a charging-switch consisting of a polarized electromagnet and contacts controlled thereby, a circuit including the battery, the source of electricity, the magnet and the contacts in series and means for manually closing the contacts to complete the circuit.

2. The combination of a storage battery, a source of electricity, a charging-switch consisting of a polarized electromagnet and contacts controlled thereby, a circuit including the battery, the source of electricity, the magnet and the contacts in series, means for manually closing the contacts to complete the circuit and an indicator adapted to show whether the circuit remains closed.

3. A charging-switch for storage batteries, consisting of an electromagnet and a polarized armature, contacts controlled by said armature and covered from view and an indicator showing the position of the contacts.

4. A charging-switch consisting of a box or casing, containing an electromagnet, a polarized armature for the electromagnet, contacts controlled by the polarized armature, the armature extending to the outside of the box and thus showing its position, and means for connecting a source of electricity and a battery in series with the magnet and contacts, substantially as described.

707,700. APPLE-PARER. JESSE JACOBS, Hanley, Cal. Filed June 14, 1901. Serial No. 64,551. (No model.)



Claim.—1. In a machine of the character described, the combination of a revolvable carriage and means for operating the same, a fork upon which an apple is capable of being held and revolved, a normally retracted, spring-pressed member axially in line with the fork and slidable in relation to the fork, a lever fulcrumed between its ends and having one end to engage said slidable member and a cam on the carriage adapted to engage the other end of said lever thereby oscillating the lever to cause the slidable member to eject the apple from the fork.

2. In a machine of the character described the combination with a revolvable carriage, a fork and means for rotating the same, and a paring mechanism, of a spring-pressed sliding bar disposed in line with the fork and having a point upon which the fruit is placed, means for retracting the bar and holding it in its retracted position, and a trigger mechanism actuated by the carriage to release the bar and allow the latter to place the fruit upon the fork.

3. In a machine of the character described the combination in a single organism of a normally retracted spring-pressed means for positioning the fruit; axially in line with fruit-holding devices; means for releasing the fruit-positioning devices to enable the latter to transfer the fruit to holding devices; means for holding and paring the fruit; a coring mechanism, means for slicing the fruit; means for ejecting the fruit; a revolvable carriage and connections for operating the paring and slicing mechanism; and a single power-wheel in operative connection with the carriage, the fruit-holding devices and coring mechanism.

4. In a paring, coring and slicing machine the combination of a revolvable fork, an axially-alined carrier-bar by which the apple is placed upon said fork, means by which said bar is retracted, a trigger mechanism whereby said bar is held in such retracted position, a revolvable table having a part to contact with said trigger by which said trigger is released and the apple driven upon the fork, and a single power mechanism for rotating the fork and table and effecting the release of the carrier-bar.

5. In a paring, corer and slicer, the combination of a revolvable fork, an axially-alined carrier-bar upon which the apple is first impinged, a spring in conjunction with said bar, a lever by which said bar is retracted and the spring compressed, a trigger mechanism by which said bar is held in such retracted position, a revolvable member for releasing said trigger whereby the apple is driven upon the fork, a single power mechanism for operating the fork and revolvable member, and means for removing the apple from the fork.

6. In a paring, corer and slicer, the combination with a fork and a means including a normally retracted, spring-actuated bar disposed in line with the fork for automatically placing the fruit upon said fork, of a revolvable carriage, and connections between the same and the bar whereby said bar is automatically released during the revolution of the carriage, a paring thereon, said paring having a projection beneath the carriage and a semicircular cam with which said projection is adapted to engage whereby the paring is held out of contact with the apple after the process of paring is complete, and a single power mechanism for operating the fork, carriage and paring.

7. In a paring, corer and slicer, the combination of a fork, a turn-table, a paring thereon, a vertically-disposed knife having a horizontal projecting portion, means including a worm-shaft and devices carried by the knife and engaging said shaft, for advancing said knife periodically toward the head of the machine whereby the apple or like fruit is simultaneously sliced and cored, said horizontal portion of the knife capable of severing the core from the sliced fruit and means by which said fork, turn-table and knife are operated in unison.

8. In an apple paring, corer and slicer, the combination of a slidable and rotatable shaft, a knife secured thereon a second shaft parallel with the first shaft, a worm-gear on said second shaft, means by which the latter is revolved, and a fingered guide on said knife, said guide adapted to engage said worm whereby the knife is made to travel horizontally.

9. In a combined paring, corer and slicer, a turn-table, a paring thereon, means for holding an apple in relation to said paring, a slicing and coring knife turnable in a plane at right angles to the axis of the machine and movable in the line of direction of said axis, a second shaft having a worm thereon, a lever-arm by which said knife is held in a raised position during a portion of the revolution of the turn-table, and means by which said arm is released to allow said knife to fall, and means carried by the knife and adapted to engage said worm whereby the knife is advanced horizontally.

10. In a combined paring, corer and slicer, a turn-table, a paring thereon, means for holding an apple or the like in relation to said paring, a rotatable and slidable shaft, a knife thereon, a horizontal projecting cutting portion on said knife, a second shaft in relation to the first shaft, a worm on said second shaft, a lever-arm by which said knife is periodically held out of contact with said worm, means by which said arm is released to allow said knife to fall, means by which said knife is advanced upon said worm, and means whereby the first shaft and knife are retracted at the completion of the slicing and coring operation.

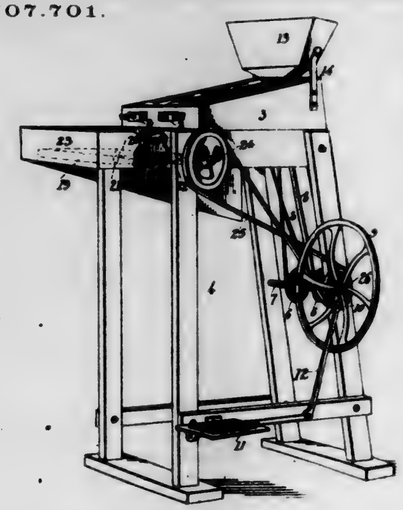
11. An apple paring, slicing and coring machine, consisting in the combination of an inclined support, a turn-table, a hollow fork upon which the apple to be pared, sliced and cored is held, a plunger operating in said fork, means including a normally retracted spring-pressed bar in line with the fork for automatically delivering the apple upon said fork, means for holding the bar retracted said means automatically releasing said bar by the revolution of the turn-table, a paring on said turn-table, a vertically and horizontally operating knife whereby the apple is sliced and simultaneously cored, and means for operating the plunger whereby the pared, sliced and cored fruit is ejected from the fork, and a single power mechanism for rotating the turn-table, fork and cutting in operation the knife, the delivering means and the ejector.

707,701. SEPARATOR. GEORGE M. JACKSON, Catharine, N. Y. Filed Apr. 26, 1901. Serial No. 57,453. (No model.)

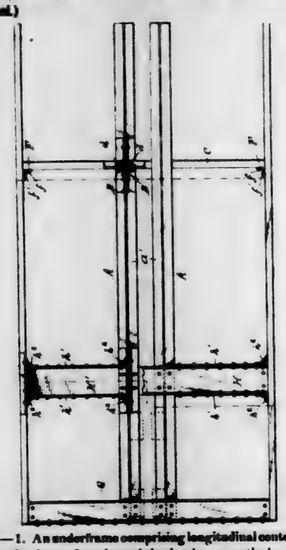
Claim.—1. In a separating-machine, the combination of a pair of inclined separating-rollers disposed apart but in proximity to each other, to permit small particles to drop through the space between them, means to rotate said rollers in opposite directions so that their opposing sides move upwardly to prevent larger particles from becoming crushed between them, laterally-adjustable bearings for the rollers, to vary the width of the space between them, a hopper to discharge onto the upper ends of said rollers, and a horizontally-disposed endless traveling conveyer having its inner side disposed under the lower ends of said rollers, substantially as described.

2. In a combination in a separating-machine, of a pair of inclined separating-rollers, pulleys carried by said rollers, a hopper to discharge onto the elevated portions of said rollers, an agitator in said hopper, connections between said agitator and one of said pulleys, whereby said agitator is operated, an endless traveling horizontally-disposed conveyor, onto which said rollers discharge, said conveyor extending outwardly from said rollers, a power-shaft and connections between the same and said conveyor and roller-pulleys, substantially as described.

707,701.



707,702. UNDERFRAME FOR RAILWAY-CARS. HERBERT R. KETHLEY, Buffalo, N. Y. Filed June 14, 1902. Serial No. 111,660. (No model.)



Claim.—1. An underframe comprising longitudinal center sills spaced apart each in the form of a plate-girder having a vertical web-plate and upper and lower flanges, transverse transoms which extend through the web-plates of said center sills and are connected thereto, and bolsters connected to said center sills, substantially as set forth.

2. An underframe comprising longitudinal center sills spaced apart each in the form of a plate-girder having a vertical web-plate and upper and lower flanges, transverse transoms which extend through the web-plates of said center sills and are connected thereto, side sills supported by said transoms, and bolsters connected to said center and side sills, substantially as set forth.

3. An underframe comprising longitudinal center sills spaced apart each in the form of a plate-girder having a vertical web-plate and upper and lower flanges, the web-plate of said girder being deeper at its central portion than at its end portions, transverse transoms which extend through the web-plates of said center sills and are connected thereto, and bolsters connected to said center sills, substantially as set forth.

4. An underframe comprising longitudinal center sills spaced apart each in the form of a plate-girder having a vertical web-plate, upper and lower flanges, and vertical flanged bars riveted to the web-plate, transverse transoms which extend through openings in the web-plates of said center sills and are riveted to said vertical flanged bars, and bolsters connected to said center sills, substantially as set forth.

5. An underframe comprising longitudinal center sills spaced apart each in the form of a plate-girder having a vertical web-plate, upper and lower flanges and vertical flanged bars riveted to the web-plate, transverse transoms which extend through openings in the web-plates of said center sills and are riveted to said vertical flanged bars, side sills supported by said transoms, and bolsters connected to said center and side sills, substantially as set forth.

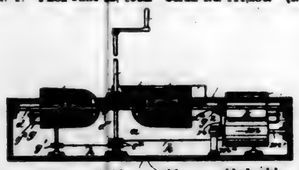
6. An underframe comprising longitudinal center sills spaced apart each in the form of a plate-girder having a vertical web-plate, upper and lower flanges, and vertical angle-bars riveted to the web-plate, transverse transoms each in the form of a flanged beam which extends through openings in the web-plates of the center sills and is riveted to the vertical angle-bars, angle-bars riveted to said transoms and to said web-plates of the center girders, side sills supported by said transverse transoms, and bolsters connecting said center and side sills, substantially as set forth.

7. In an underframe, longitudinal center sills spaced apart and bolsters each comprising a flanged beam resting on the center sills and secured to the same, a flanged beam arranged beneath and secured to the center sills, and members connecting said flanged beams at opposite sides of said center sills, substantially as set forth.

8. An underframe comprising longitudinal center sills spaced apart, transverse transoms which are supported by and extend to opposite sides of said center sills, side sills supported by said transoms, and bolsters connecting said center and side sills, each bolster comprising a flanged beam resting on the center sills and secured to the same and to the side sills, a flanged beam arranged beneath and secured to the center and side sills, and plates connecting said flanged beams at opposite sides between the center and side sills, said plates being connected to the center and side sills, substantially as set forth.

9. An underframe comprising longitudinal center sills spaced apart and each formed with tension and compression members, a plate connecting the central portions of said tension and compression members, transverse transoms which extend through openings in said plates and are secured thereto, and bolsters connected to said center sills, substantially as set forth.

707,708. SHOE-POLISHING MACHINE. MORITZ LEVY, New York, N. Y. Filed June 12, 1902. Serial No. 111,266. (No model.)



Claim.—1. A shoe-polishing machine provided with a slotted top, and a hollowed rotating brush projecting partly above the same and having inwardly-extending bristles, substantially as specified.

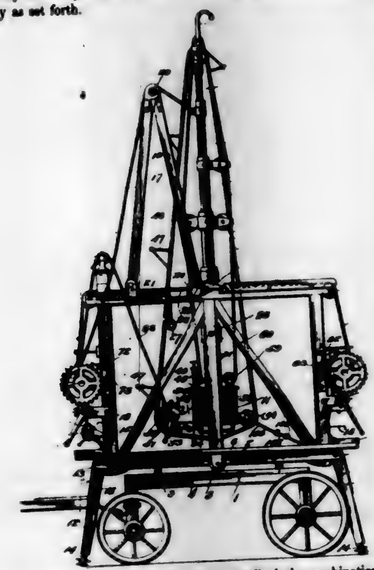
2. A shoe-polishing machine provided with a slotted top, an endless polishing-cloth projecting through the same, and a rotating drum engaging said cloth, substantially as specified.

3. A shoe-polishing machine provided with a box having a slotted top, an endless polishing-cloth projecting through the same, frames for supporting the cloth above the slotted top, and a rotating drum within the box that engages the cloth, substantially as specified.

707,704. FIRE TRUCK AND LADDER. HARVEY W. LLOYD, Southwest City, Mo. Filed May 19, 1902. Serial No. 108,000. (No model.)

Claim.—1. In an apparatus of the character described, the combination of a supporting-frame, a derrick thereon, adapted to be raised and lowered, a telescopic ladder pivotally mounted in the frame, means for raising and lowering the derrick, means operating in connection with the derrick for elevating the ladder from a horizontal to a vertical position, means for adjusting the ladder to the horizontal position, and means for projecting and retracting the telescopic sections of the ladder, substantially as described.

2. In an apparatus of the character described, the combination with a supporting-frame provided with sockets; of a derrick-frame adapted to be raised and lowered and having movable arms adapted to be seated when the derrick is raised in said sockets, an extensible ladder, means operating with the derrick-frame for elevating and adjusting the ladder to a position for use, means for elevating and lowering the derrick-frame, and elevating devices for lifting the arms of the derrick out of said sockets preliminary to the operation of the means for lowering said derrick, substantially as set forth.



3. In an apparatus of the character described, the combination with a supporting-frame; of winding-shafts upon the front and rear of said frame, each of said shafts carrying sheave-drums, a derrick adapted to be raised and lowered, an extensible ladder mounted to swing vertically in the frame and adapted to be adjusted to a horizontal position to project its sections and to a vertical position for use, cables connected to certain of the winding-drums upon said winding-shafts to raise and lower the derrick, other cables connected to other drums upon one of the winding-shafts and coöperating with the derrick to elevate the ladder to a vertical position for use, and cables also connected with the winding-drums on the two shafts for adjusting the ladder to a horizontal position and steadying it in a vertical position, substantially in the manner described.

4. In an apparatus of the character described, a ladder composed of tubular telescoping sections, each section comprising tubular side rails, couplings connected to said rails and forming reducing-tubes for the rails of the connecting-section to slide through, cross-bars connecting said couplings, ladders having a detachable pivotal connection with the cross-bars and adapted to slide one down upon the other when the sections are retracted and notched to provide cam-shoulders to engage the cross-bars, and springs fixed at one end to the cross-bars and bearing at their free ends on rounds of the ladders for retaining the ladders yieldingly in position with the cam-shoulders engaging the cross-bars, substantially as and for the purpose specified.

5. In an apparatus of the character described, the combination with a supporting-frame having guideways upon the upper rear portion thereof and stops at the forward ends of said guideways; of a derrick-frame adapted to be raised and lowered and having movable arms slidable in said guideways and adapted to engage said stops, a ladder mounted to swing within the frame, means coöperating, in part, with the derrick-frame for adjusting the ladder, means for raising and lowering the derrick-frame, pivoted plates for elevating the free arms of the derrick-frame out of engagement with said stops, and means for operating the said plates, substantially as specified.

707,705. MECHANICAL MOVEMENT. THOMAS J. LOCKWOOD, Muncie, Ind., assignor to Jennnette M. Lockwood, Muncie, Ind. Filed Dec. 4, 1901. Serial No. 84,603. (No model.)

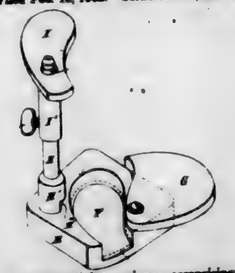
Claim.—1. In a mechanical movement, the combination with a support, of a movable reciprocating member to which power is adapted to be applied, a second movable member arranged at right angles to the first-mentioned movable member, the second movable member being provided with a cut-out portion having sides converging toward each other at their inner ends, a dog pivoted within the cut-out portion, the inner side portions of the dog and the sides of the cut-out portion forming oppositely-extending grooves, the inner end of the dog being adapted to close either one of the grooves according to the position of the dog, a pin carried by the first movable member adapted to work in either one of the grooves, and means carried by the first movable member for reversing the position of the dog at each full reciprocation of the same.

2. In a mechanical movement, the combination with a support, of a movable reciprocating member to which power is adapted to be applied, a second movable member arranged at right angles to the first-mentioned movable member, the second movable member being provided with a cut-out portion having sides converging toward each other at their inner ends, the inner ends being spaced apart forming an end for the cut-out portion, a dog pivoted within the cut-out portion, the inner side portions of the dog and sides of the cut-out portion forming oppositely-extending grooves, the inner end of the dog being adapted to close either one of the grooves according to the position of the dog, a pin carried by the first movable member adapted to work in either one of the grooves, the pin adapted to strike against the end of the cut-out portion when the first movable member is in one position thereby limiting the movement of the same, and means carried by the first movable member for reversing the position of the dog at each full reciprocation of the same.

3. In a mechanical movement, the combination with a support, of a movable reciprocating member to which power is adapted to be applied, a second movable member arranged at right angles to the first-mentioned movable member, the second movable member being provided with a cut-out portion having sides converging toward each other at their inner ends, shoulders on the sides located adjacent the open ends of the same, a dog pivoted within the cut-out portion, the upper side portions of the dog and sides of the cut-out portion forming oppositely-extending grooves, the inner end of the dog being adapted to close either one of the grooves according to the position of the dog, a pin carried by the first movable member adapted to work in either one of the grooves, the pin adapted to strike against either one of the shoulders when the first movable member is in one position thereby limiting the movement of the same and means carried by the first movable member for reversing the position of the dog at each full reciprocation of the same.

4. In a mechanical movement, the combination with a support, of a movable reciprocating member to which power is adapted to be applied, a second movable member arranged at right angles to the first-mentioned movable member, the second movable member being provided with a cut-out portion having sides converging toward each other at their inner ends, a dog pivoted within the cut-out portion, the inner side portions of the dog and sides of the cut-out portion forming oppositely-extending grooves, the inner end of the dog being adapted to close either one of the grooves according to the position of the dog, the outer side portions of the dog converging in opposite directions from the inner side portions of the dog, a pin carried by the first movable member adapted to work in either one of the grooves, and a second pin carried by the first movable member adapted to bear against each outer side of the dog alternately at each full reciprocation of the first movable member.

707,706. EXTENSION-PEDAL FOR PIANOS. EUGENE F. LOTSPEICH, Los Angeles, Cal., assignor of one-third to W. F. Botsford, Los Angeles, Cal. Filed Feb. 12, 1902. Serial No. 93,795. (No model.)



Claim.—An extension-pedal for pianos, comprising a base having therein a recess adapted to receive the pedal of the piano; a lid pivoted

to said base and adapted to be turned over the pedal when placed therein and hold the pedal firmly in the recess; an upright on said base; an auxiliary pedal, having a downwardly-projecting socket to receive the upright and rest thereon, and an adjusting hand-screw in said socket.

707,707. ADJUSTABLE STANDARD FOR MIRROR-FRAMES, &c. JACOB LOWENTHAL, Chicago, Ill. Filed Feb. 3, 1902. Serial No. 92,142. (No model.)

Claim.—1. The combination of a frame, a backing, such backing secured in the frame, a bracket, such bracket provided with a hole adjacent to one end thereof and provided with a circular and concentric with the hole, a U-shaped piece, a pivot, such U-shaped piece provided with a hole near the bend therein and attached to the bracket by extending the pivot through the holes in the U-shaped piece and in the bracket, a shaft, such shaft flattened at its ends and arranged relative to the U-shaped piece and bracket to be interposed between the bend of the U-shaped piece and the circular end of the bracket, a base, such base provided with friction springs stamped out of and forced up therefrom, and such base interposed between the shaft and the backing of the frame, and means to attach the base and the flattened ends of the shaft to the backing; substantially as described.

2. The combination of a frame, a backing, such backing secured in the frame, a bracket, such bracket provided with a hole adjacent to one end thereof and with recesses in its sides near the hole, and provided with a circular end concentric with the hole, a U-shaped piece, a pivot, such U-shaped piece provided with a hole near the bend therein and attached to the bracket by extending the pivot through the holes in the U-shaped piece and in the bracket, springs interposed between the bracket and the U-shaped piece and held in the recesses in the bracket by the U-shaped piece, a shaft, such shaft flattened at its ends and arranged relative to the U-shaped piece and the bracket to be interposed between the bend of the U-shaped piece and the circular end of the bracket, a base, such base provided with friction-springs stamped out of and forced up therefrom, and such base interposed between the shaft and the backing, and means to attach the base and the flattened ends of the shaft to the backing; substantially as described.

707,708. ROLLER-GRATE. JOHN MACCORMACK, Bayonne, N. J., assignor to Royal C. Peabody, Brooklyn, N. Y. Filed Dec. 18, 1901. Serial No. 86,290. (No model.)

Claim.—1. A roller-grate bar having in combination a shaft, a sectional supporting-frame removably secured thereto, and a sectional screen-surface removably secured to said supporting-frame, substantially as set forth.

2. In a roller-grate bar, the combination with the two semicircular supporting-frames clamped together, of two semicircular screen-sections having inwardly-turned edges clamped between the meeting edges of the sections of the supporting-frame, substantially as set forth.

3. A roller-grate bar having in combination the shaft, the semicircular frames secured to said shaft, and the semicircular screen-sections clamped between the meeting edges of the semicircular frames, substantially as set forth.

707,709. HAY-BALING PRESS. ROBERT S. MEAD, Winona, Minn. Filed Oct. 28, 1901. Serial No. 79,609. (No model.)

Claim.—1. In a baling-press, the longitudinal closure or box having an admission-opening for the hay, and an end abutment, the chamber of such box having a flare from admission-opening to abutment, substantially as specified.

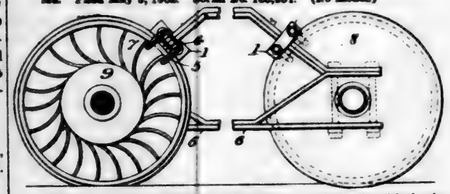
2. The head hay-press, consisting of the longitudinal box, having a door forming an end abutment, the chamber of such box having a flare toward such abutment, substantially as specified.

3. The head hay-press, consisting of the longitudinal box having a door forming an end abutment, a hopper near one end, the press-head having a rack extension, and the crushed shaft carrying a pinion in mesh with such rack, the chamber of such box having a flare toward such abutment, substantially as specified.

707,710. ROOFING COMPOUND. FRANK A. MITCHELL, Washington, D. C. Filed Dec. 10, 1901. Serial No. 85,397. (No specimens.)

Claim.—The herein-described roofing composition of bolted slate-flour, powdered soapstone, coal-tar, sour milk and creosotine in the proportions, substantially as specified.

707,711. WHEEL-CLAMP. EDWARD J. HAFNER, Westernport, Md. Filed May 3, 1902. Serial No. 105,831. (No model.)



Claim.—1. In a portable car-wheel clamp, a yoke, hooks with shanks therefor, said shanks adapted to be adjustably secured to said yoke, a link loosely mounted upon said shanks and in advance of said yoke, the whole providing means whereby the device may be clamped upon a portion of a car-truck frame and lock a wheel thereof rigidly to said frame, substantially as described.

2. In a wheel-clamp, a rod or shank bent into the form of a hook at one end, and screw-threaded at the other, a block adapted to be secured to a vehicle-frame, and to receive the threaded end of said shank, and the hooked end to engage the vehicle-wheel, substantially as described.

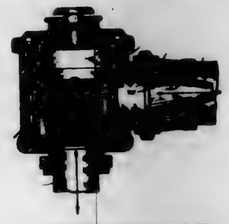
3. In a wheel-clamp, a perforated block or yoke, shanks bent into the form of a hook at one end, and screw-threaded at the other, adapted to adjustably engage the perforations in said yoke, screw-nuts for securing said shanks to said yoke, and a link loosely mounted on said shanks, substantially as described.

707,712. FLOW-REDUCING DEVICE. JOSEPH W. HETHERY, Indianapolis, Ind., assignor to the Hethery Hydraulic Valve Company, Indianapolis, Ind., New York, N. Y., and Jersey City, N. J., a Corporation of New Jersey. Filed Dec. 18, 1901. Serial No. 86,373. (No model.)

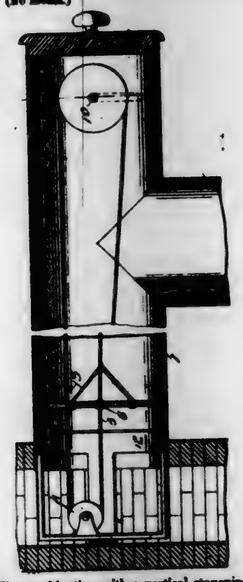
Claim.—1. The combination, with the pipes of a fluid-distribution system, of a flow-reducing device consisting of a conical tube secured within such pipe and arranged with its smaller end pointing toward the direction from which the flow comes, substantially as set forth.

2. A flow-reducing device adapted to be secured within the pipe of a fluid-distribution system, consisting of a conical tube provided with graduation-marks indicating pressure quantity, and adapted to be cut off at such score-marks and thereby adapted to be used at the pressure indicated, substantially as set forth.

3. The combination, in a fluid-distribution system, with the pipes thereof, of a flow-reducing device consisting of a conical tube adapted to be placed within said pipe, said device being provided with a flange whereby it may be secured at the union or pipe-coupling, substantially as set forth.



707,713. STOVEPIPE-CLEANER. BARRETT C. OBLINGER and ALBERT H. C. BEATTY, Independence, Mo. Filed July 8, 1901. Serial No. 67,571. (No model.)

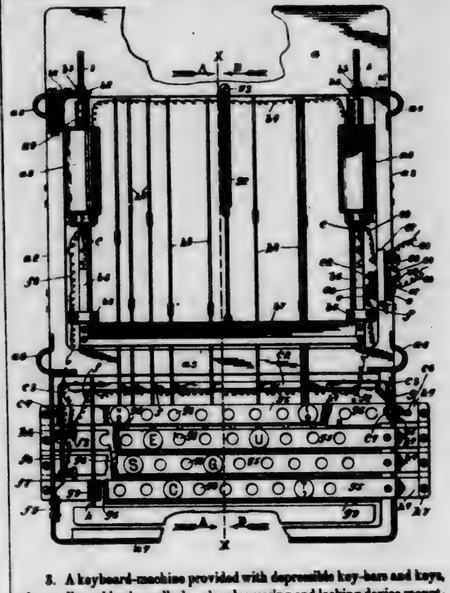


Claim.—The combination with a vertical stovepipe and a horizontal stovepipe connected thereto, the latter having its outer end extending outwardly beyond the junction with the vertical pipe and provided at its outer end with a removable cap and being further provided at its inner end with an open frame which enters the chimney, wheels mounted respectively in the outer extension of the horizontal pipe and in the said open frame, the first-mentioned wheel having a crank by which it may be rotated, an endless chain connecting said wheels and extending through the horizontal pipe, and a scraper connected to one lead of said chain, said scraper being adapted to be drawn by said chain through the horizontal pipe into the chimney, for the purpose set forth, substantially as described.

707,714. KEYBOARD-MACHINE. THEODORE W. OTTO, Stamford, Conn. Filed Oct. 23, 1901. Serial No. 79,676. (No model.)

Claim.—1. A keyboard-machine provided with depressible keys and key-bars, a member mounted transversely of the machine rearwardly of the keyboard, electrical devices for moving said member forwardly when one or more of the keys are given an initial downward movement, devices connected with the key-bars and operated upon by said member for completing the downward movement of the key or keys and means for moving said member backwardly, substantially as shown and described.

2. A keyboard-machine provided with key-bars and keys, a key-bar locking and depressing device mounted rearwardly of the keyboard and transversely of the machine and movable forwardly and backwardly, electrical devices for moving said first-named device forwardly and for depressing such key-bars as have been given an initial downward movement and for locking the others, and means for moving said first-named device backwardly, substantially as shown and described.



3. A keyboard-machine provided with depressible key-bars and keys, a forwardly and backwardly key-bar depressing and locking device mounted transversely of the machine rearwardly of the keyboard and adapted to depress the key-bars after they have been given an initial downward movement and lock those which have not been given an initial downward movement, said device being in an electric open circuit which is closed by an initial downward movement of the key bar or bars at which time said device is drawn forwardly and means for moving said device backwardly, substantially as shown and described.

4. A keyboard-machine provided with depressible key-bars and keys, a forwardly and backwardly key-bar depressing and locking device mounted rearwardly of the keyboard and transversely of the machine, electrical devices for moving said first-named device forwardly when a key-bar has been given an initial downward movement and means for moving said device backwardly, substantially as shown and described.

5. A keyboard-machine provided with depressible key-bars and keys, an electrically-operated device for completing the depression of one of the key-bars after it has been given an initial downward movement and means whereby the said device locks all the key-bars which are not given an initial downward movement, substantially as shown and described.

6. A keyboard-machine provided with depressible key-bars and keys, a key-bar depressing and locking device mounted transversely of the machine and rearwardly of the keyboard and movable forwardly and backwardly, said device being in an open electric circuit which is closed by an initial movement given to one or more of the key-bars and by which said device is drawn forwardly, and means for moving said device backwardly, said key-bars being also provided with devices operating in connection with said first-named device whereby the forward movement of said first-named device depresses the key-bars that have been given an initial movement and locks the remainder thereof, substantially as shown and described.

7. A keyboard-machine provided with depressible key-bars and keys, solenoids mounted at the opposite sides of the rear portion of the machine and provided in their rear ends with longitudinally-movable plungers, bars passing into the front ends of the said solenoids and connected by a transverse key-bar, depressing and locking device, a transverse bar pivoted beneath the rear portion of the keyboard and normally held against the bottom of the key-bars, contact devices at one side of the keyboard, one of which is connected with said pivot-bar, said contact devices being in electrical connection with said solenoids, and means whereby the key-bar depressing and locking device operates to complete the depression of one of said bars after it has been given an initial downward movement and to lock the other bars, substantially as shown and described.

8. A keyboard-machine provided with depressible key-bars and keys.

solenoids mounted at the opposite sides of the rear portion of the frame of the machine and provided at their rear ends with plungers a^6, slide-bars b^6 mounted in the front ends of said solenoids and connected by a cross-bar b^7, a vertically-movable transverse bar c^3 mounted beneath the rear portion of the keyboard and provided with forwardly-directed members c^4 which are pivoted to the opposite sides of the frame of the machine, means for holding said bar c^3 in the raised position against the bottom of the key-bars, electrical contact devices at one side of the keyboard, one of which is connected with said bar c^3 said contact devices being also in electrical connection with said solenoids, and said solenoids being in electrical connection, and a switch device placed at one side of the machine and in a circuit formed by the solenoids, the connecting-wires and said contact devices, said switch device being provided with circuit-wires, substantially as shown and described.

9. A keyboard-machine provided with depressible key-bars and keys, a forwardly and backwardly movable device mounted rearwardly of the keyboard, devices whereby the forward movement of the said first-named device depresses a key-bar after it has been given an initial downward movement and locks all the other key-bars, said device being mounted in an open electrical circuit the closing of which moves said device forwardly, means whereby the depression of a key opens and closes said circuit and means for moving said device backwardly, substantially as shown and described.

10. A keyboard-machine provided with depressible key-bars and key-tubes by which the keys are supported, stationary transverse plates in which said tubes are mounted and vertically movable, movable plates mounted beneath said tubes and provided with openings adapted to receive the same, said tubes being provided with springs in the lower ends thereof and with slots and said key-bars being provided with members which pass through said slots between said stationary plates, substantially as shown and described.

11. A keyboard-machine provided with depressible key-bars and key-tubes by which the keys are supported, stationary transverse plates in which said tubes are mounted and vertically movable, movable plates mounted beneath said tubes and provided with openings adapted to receive the same, said tubes being provided with springs in the lower ends thereof and with slots and said key-bars being provided with members which pass through said slots between said stationary plates, and devices whereby said key-bars are automatically depressed to the desired extent after they have been given an initial downward movement, substantially as shown and described.

12. A keyboard-machine provided with depressible key-bars and key-tubes by which the keys are supported, stationary transverse plates in which said tubes are mounted and vertically movable, movable plates mounted beneath said tubes and provided with openings adapted to receive the same, said tubes being provided with springs in the lower ends thereof and with slots and said key-bars being provided with members which pass through said slots between said stationary plates, and devices whereby said key-bars are automatically depressed to the desired extent after they have been given an initial downward movement, the key-bars which have not been given an initial downward movement being at the same time locked by said devices, substantially as shown and described.

13. A keyboard-machine provided with the usual key-bars, vertically-arranged tubes forming key-supports, said tubes being arranged in rows, transversely-arranged plates through which said tubes pass and in which said tubes are free to move, movable plates mounted beneath said tubes, and provided with openings adapted to receive said tubes, said key-bars being provided with members which pass through slots formed in said tubes and springs placed in said tubes and upon which said members bear, substantially as shown and described.

14. A machine of the class described provided with a plurality of key-bars and vertically-movable key-tubes, said tubes being slotted and adapted to receive members connected with said bars, movable plates mounted beneath said key-tubes and provided with openings adapted to receive the same and devices adapted to depress said key-bars to the desired extent after they have been given an initial downward movement, substantially as shown and described.

15. A keyboard-machine provided with key-supporting tubes which are vertically movable, stationary transverse plates through which said tubes pass, movable plates mounted below said tubes and provided with openings adapted to receive the same, and means whereby the key-bars, after they have been given an initial downward movement, are automatically depressed to the desired extent, substantially as shown and described.

16. A keyboard-machine provided with key-supporting tubes which are vertically movable, stationary transverse plates through which said tubes pass, movable plates mounted below said tubes and provided with openings adapted to receive the same, and means whereby the key-bars, after they have been given an initial downward movement, are automatically depressed to the desired extent, said devices also serving to lock the key-bars which are not depressed, substantially as shown and described.

707,715. FIRE-ESCAPE. Simon B Parker, Springfield, Mass. Filed June 9, 1902. Serial No. 110,827. (No model.)

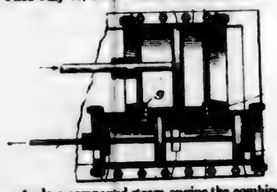
Claim.—1. A fire-escape consisting of a flexible wire cable or rope comprising a series of links loosely connected together, and suitable means upon the upper ends of said links whereby one link is held against laterally sliding upon the adjacent link to which it is connected, substantially as and for the purpose set forth.

2. A fire-escape consisting of a flexible wire cable or rope, comprising a series of loosely-jointed links, and stops upon the upper ends of the links to hold the same against laterally sliding upon each other, substantially as and for the purpose described.

3. A fire-escape consisting of a flexible wire cable or rope comprising a series of links provided with shanks having means for engaging the shanks with the adjacent links, and stops upon the upper ends of the links to hold the same against sliding laterally upon each other, substantially as and for the purpose specified.

4. A fire-escape consisting of a flexible wire cable or rope comprising a series of links provided with twisted shanks at their lower ends terminating in hooks or other like means for engaging the adjacent link, and stops upon the upper ends of the links to hold said links against laterally sliding upon each other, substantially as and for the purpose set forth.

707,716. COMPOUND STEAM-ENGINE. John Patten, New York, N. Y. Filed July 16, 1901. Serial No. 68,461. (No model.)



Claim.—1. In a compound steam-engine the combination of a high-pressure cylinder having a valve-controlled steam-inlet port at one end and a central exhaust-port, a low-pressure cylinder having a port at one end communicating with the high-pressure cylinder between the steam inlet and exhaust ports of the latter, a piston within the low-pressure cylinder and a pair of connected piston-heads in the high-pressure cylinder, one of said heads being movable between said steam and exhaust ports and adapted to pass beyond the port communicating with the low-pressure cylinder in each direction of its movement, thereby connecting said communicating port alternately with the steam-space of the high-pressure cylinder and with the exhaust-port, and the other head being movable between the exhaust-port and the opposite end of the cylinder.

2. In a compound steam-engine the combination of a high-pressure cylinder having a valve-controlled steam-inlet port at one end and a central exhaust-port, a low-pressure cylinder having a port at one end communicating with the high-pressure cylinder between the steam inlet and exhaust ports of the latter, a piston within the low-pressure cylinder and a pair of connected piston-heads in the high-pressure cylinder, one of said heads being movable between said steam and exhaust ports and adapted to pass beyond the port communicating with the low-pressure cylinder in each direction of its movement, thereby connecting said communicating port alternately with the steam-space of the high-pressure cylinder and with the exhaust-port, and the other head being movable between the exhaust-port and the opposite end of the cylinder, a crank-shaft and cranks to which the pistons in the high and low pressure cylinders are connected, the angular relation of the cranks being less than one hundred and eighty degrees.

3. In a compound steam-engine the combination of a high-pressure cylinder having valve-controlled steam-inlets at both ends and a central exhaust-port, a low-pressure cylinder having ports at both ends communicating with the high-pressure cylinder at opposite sides of said central port, a piston in the low-pressure cylinder movable between the communicating ports and two pistons in the high-pressure cylinder movable across said communicating ports and operating as valves therefor.

4. In a compound steam-engine the combination of a high-pressure cylinder having valve-controlled steam-inlets at both ends and a central exhaust-port, a low-pressure cylinder having ports at both ends communicating with the high-pressure cylinder at opposite sides of said central port, a piston in the low-pressure cylinder movable between the communicating ports, two pistons in the high-pressure cylinder each movable across one of said communicating ports, a crank-shaft, and cranks to which said pistons are connected, the angular relation of the cranks being less than one hundred and eighty degrees.

5. In a compound steam-engine the combination of a high-pressure cylinder having valve-controlled steam-inlet ports at both ends and a central exhaust-port, a low-pressure cylinder having ports at both ends communicating with the high-pressure cylinder at opposite sides of said exhaust-port, a piston in said low-pressure cylinder, and two connected pistons in the high-pressure cylinder on opposite sides of said exhaust-port, each piston in the high-pressure cylinder being movable across one of said communicating ports and operating as a valve therefor.

707,717. GARMENT-SUPPORTER. Sally C. Pearson, Montgomery, Ala. Filed Nov. 23, 1901. Serial No. 83,430. (No model.)

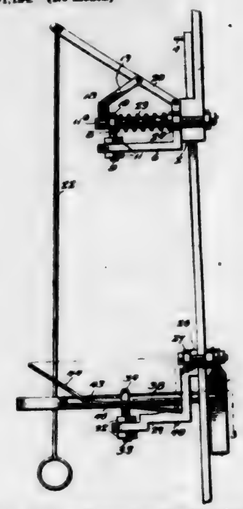
Claim.—1. In a garment-supporter, the combination of a belt or waistband, suspender-straps connected thereto, upwardly and outwardly directed skirt-supporting projections carried by the back of the belt to form a ledge over which a skirt is adapted to be snugly drawn, and hose-supporters connected to the front of the belt.

2. In a garment-supporter, the combination of a belt or waistband, suspender-straps connected thereto, a plate secured to the back of the belt and having upwardly and outwardly directed skirt-supporting projections to form a ledge over which a skirt is adapted to be snugly drawn, and hose-supporters connected to the front of the belt.

3. In a garment-supporter, the combination of a belt or waistband, suspender-straps connected thereto, hose-supporters connected to the front of the belt and at the points of attachment of the shoulder-straps, and upwardly and outwardly directed skirt-supporting projections carried by the back of the belt and located at the points of attachment of the rear ends of the shoulder-straps.

4. In a garment-supporter, the combination of a belt or waistband, shoulder-straps crossed at the back and having their ends connected respectively to the front and rear of the belt, the straps being connected at their point of crossing, a button carried by the front portion of one of the shoulder-straps, a tab carried by the corresponding portion of the other shoulder-strap and provided with a buttonhole for the reception of the button, hose-supporters hang from the front portion of the belt, and skirt-supporting projections carried by the rear portion of the belt and inclined upwardly and outwardly therefrom.

707,718. COUPLING MECHANISM FOR WINDMILLS AND PUMPS. William F. Pflueger, Altona, Nebr. Filed Jan. 24, 1902. Serial No. 91,134. (No model.)



Claim.—1. In a coupling mechanism of the class set forth, the combination of a windmill reciprocating bar having a socket, a pump-rod slidably engaging said socket, a spring-actuated coupling-bolt for connecting the said rod, and a loosely-depending pull-rod and lever mechanism connected to and adapted for withdrawing the bolt into uncoupling position.

2. In a coupling mechanism of the class set forth, the combination of a windmill reciprocating element, a pump-rod arranged in operative relation to said element, a spring-actuated bolt for detachably connecting the said pump-rod and element, a lever-and-link mechanism for withdrawing the said bolt, a pull-rod attached to said latter mechanism, a lower coupling-bolt slidably engaging the lower extremity of the pump-rod and through a part of which the said pull-rod depends, and a pump-operating element also engaging the said lower coupling-bolt.

3. In a coupling mechanism of the class set forth, the combination with a reciprocating element, of a supporting-frame secured thereto and having an adjustable guide-eye, and a bolt movable through the said eye, a part of the frame and the reciprocating element.

4. In a coupling mechanism of the class set forth, the combination with a reciprocating element, of a supporting-frame secured to said element and having a horizontal member with a slot therein, a guide-eye held on the said member, and a sliding bolt engaging the eye and having a pin extending into the slot, the one extremity of the bolt passing through the frame and the reciprocating element and the opposite extremity serving as guiding means for a part of adjacent mechanism.

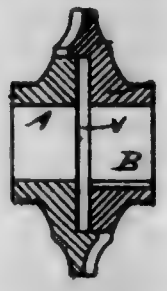
5. In a coupling mechanism of the class set forth, the combination with a supporting element, of a supporting-frame having a guide-eye thereon, a bolt slidably mounted in said eye and a portion of the frame, a part of the frame being formed with an upward incline leading to a catch-shoulder, and a catch device having an angular extremity to ride over the said incline and engage the shoulder.

707,719. CUTTER FOR GEAR-TEETH. Oliver W. Platt, Providence, R. I. Filed Mar. 15, 1902. Serial No. 98,208. (No model.)

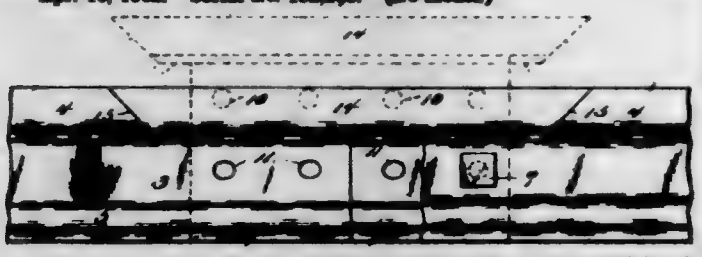
Claim.—1. A cutter of the class described, consisting of two members; each member comprising a sleeve having spaced teeth arranged to occupy the spaces respectively between the teeth of the other member; and means connected with the teeth arranged to peripherally incline the space between the opposing faces of the sleeves in different relative axial positions of the members.

2. A cutter of the class described, consisting of two members; each

member comprising a sleeve with radial spaced teeth on its periphery that have lateral extensions, which extensions occupy the spaces respectively between the teeth of the other member; each said tooth being arranged to have the inner face of its said extension in engagement with the periphery of the sleeve of the other member in different relative axial positions of the members.



707,720. RAIL-JOINT. William R. Randle, Yorkana, Pa. Filed Apr. 10, 1902. Serial No. 102,293. (No model.)



Claim.—1. In a railway-rail joint, a pair of rails provided with longitudinal mortises in their abutting ends extending vertically through the web and base and having the heads cut away on a miter to expose the mortises and leave horizontal seats, in combination with a coupling or bridge-piece embodying a central tongue to fit the mortises in the rails, and a cap or head terminally mitered to fit the extremities of the rail-heads, said cap being extended beyond the tongue at both ends to form shoulders which rest on the horizontal seats, and bolts passing through the tongue and rail ends, substantially as described.

2. In a railway-rail joint, a pair of rails provided with longitudinal mortises in their abutting ends extending vertically through the web and base and having the heads cut away on a miter to expose the mortises, in combination with a coupling or bridge-piece embodying a central tongue to fit the mortises in the rails, and a cap or head terminally mitered to fit the extremities of the rail-heads, and bolts passing through the tongue and rail ends, substantially as described.

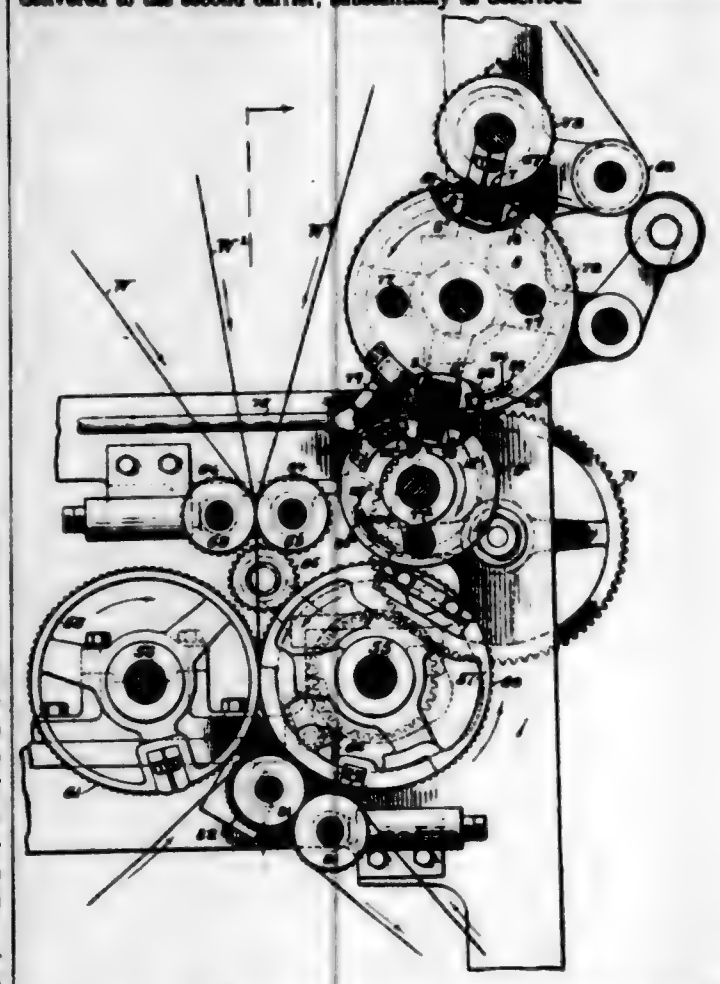
707,721. SHEET-TRANSFERRING MECHANISM. George F. Read, New York, N. Y., assignor to Robert Hoe, New York, N. Y. Filed Sept. 14, 1901. Serial No. 75,290. (No model.)

Claim.—1. In a sheet-accelerating mechanism, the combination with a forwarding mechanism running at one speed, of a forwarding mechanism running at a different speed, a transferring mechanism between the two and arranged to run at a varying speed which at times corresponds to the speed of each of the forwarding mechanisms, said transferring mechanism including a sheet-carrier having a suction-channel and an air-chamber lying along the path of movement of the carrier with which the channel is in communication, and adjustable means for interrupting the communication between the channel and the chamber, substantially as described.

2. In a sheet-accelerating mechanism, the combination with a forwarding mechanism running at one speed, of a forwarding mechanism running at a different speed, a transferring mechanism between the two and arranged to run at a varying speed which at times corresponds to the speed of each of the forwarding mechanisms, said transferring mechanism including a sheet-carrier having a suction-channel and an air-chamber lying along the path of movement of the carrier with which the channel is in communication, and an adjustable block located in the chamber for interrupting the communication between the channel and the chamber, substantially as described.

3. The combination with a sheet-carrier driven at a constant speed, said carrier having a suction-channel, of a sheet-carrier driven at a varying speed, said carrier having a suction-channel, an air-chamber for each of said carriers located along the path of movement thereof and with which the channel is in communication, and adjustable means for interrupting the communication between the channels and the chambers, whereby a sheet may be taken by the first carrier and delivered to the second carrier, substantially as described.

4. The combination with a sheet-carrier driven at a constant speed, said carrier having a suction-channel, of a sheet-carrier driven at a varying speed, said carrier having a suction-channel, an air-chamber for each of said carriers located along the path of movement thereof and with which the channel is in communication, and an adjustable block located in the chamber for interrupting the communication between the channels and the chambers, whereby a sheet may be taken by the first carrier and delivered to the second carrier, substantially as described.



5. The combination with a cylinder driven at a constant speed, said cylinder having a suction-channel, of a cylinder driven at a varying speed, said cylinder having a suction-channel, stationary heads having air-chambers with which the channels communicate, means for exhausting the air from the chambers, and an adjustable block located in each chamber for interrupting the communication between the channels and the chambers, substantially as described.

6. The combination with a sheet-carrier, of a second sheet-carrier, said carriers being constantly driven at different speeds, an intermediate transfer-carrier driven at a varying speed which corresponds at times with the speed of one carrier and at times with the speed of the other carrier, said transfer-carrier having a suction-channel, an air-chamber with which said channel is in communication lying along the path of movement of the carrier, and an adjustable block in the chamber for interrupting the communication between the channel and the chamber, substantially as described.

7. The combination with a sheet-carrying cylinder having sheet-taking devices, of a second sheet-carrying cylinder having a suction-channel, said cylinders being driven at different speeds, a stationary head having an air-chamber with which said channel communicates, a transfer-cylinder located between the sheet-carrying cylinders and having a suction-channel, a stationary head having an air-chamber with which said channel communicates, and an adjustable block in each of the chambers for interrupting the communication between the channels and the chambers, and means for driving the transfer-cylinder at a varying speed which corresponds at times with the speed of each of the sheet-carrying cylinders, substantially as described.

8. The combination with a sheet-carrying cylinder driven at a constant speed, said cylinder having a suction-channel, of a cylinder driven at a varying speed which corresponds at times with the speed of the carrying-cylinder, said cylinder having a suction-channel, air-chambers with which the suction-channels are in communication, a suction-pipe, connections from said pipe with each of the chambers, and means for interrupting the communication between the suction-channels and the air-chambers, substantially as described.

9. The combination with a sheet-carrying cylinder driven at a constant speed, said cylinder having a suction-channel, of a cylinder driven at a varying speed which corresponds at times with the speed of the carrying-cylinder, said cylinder having a suction-channel, air-chambers with which the suction-channels are in communication, a suction-pipe, connections from said pipe with each of the chambers, and means in the cham-

bers for interrupting the communication between the suction-channels and the air-chambers, substantially as described.

10. The combination with a sheet-carrying cylinder driven at a constant speed, said cylinder having a suction-channel, of a cylinder driven at a varying speed which corresponds at times with the speed of the carrying-cylinder, said cylinder having a suction channel, air-chambers with which the suction-channels are in communication, a suction-pipe, connections from said pipe with each of the chambers, and an adjustable block in each chamber for interrupting the communication between the suction-channels and the air-chambers, substantially as described.

11. The combination with a sheet-carrying cylinder driven at a constant speed, said cylinder having a suction-channel, of a grooved head with which said channel is in communication, a cylinder having a suction-channel, a grooved head with which said suction-channel is in communication, said second cylinder being driven at a varying speed which at times corresponds with the speed of the sheet-carrying cylinder, a suction-pipe, connections from said pipe to the groove in each of the heads, and means for interrupting the communication between the grooves and the channels, substantially as described.

12. The combination with a sheet-carrying cylinder driven at a constant speed, said cylinder having a suction-channel, of a grooved head with which said channel is in communication, a cylinder having a suction-channel, a grooved head with which said suction-channel is in communication, said second cylinder being driven at a varying speed which at times corresponds with the speed of the sheet-carrying cylinder, a suction-pipe, connections from said pipe to the groove in each of the heads, and means in the grooves for interrupting the communication between the grooves and the channels, substantially as described.

13. The combination with a sheet-carrying cylinder driven at a constant speed, said cylinder having a suction-channel, of a grooved head with which said channel is in communication, a cylinder having a suction-channel, a grooved head with which said suction-channel is in communication, said second cylinder being driven at a varying speed which at times corresponds with the speed of the sheet-carrying cylinder, a suction-pipe, connections from said pipe to the groove in each of the heads, and an adjustable block in each groove for interrupting the communication between the grooves and the channels, substantially as described.

14. The combination with a sheet-carrying cylinder having sheet-taking devices, of a sheet-carrying cylinder having a suction-channel, means for driving these cylinders at different speeds, a transfer-cylinder having a suction-channel, said cylinder being arranged between the two sheet-carrying cylinders, grooved heads, the grooves of which are in communication with the suction-channels of the sheet-carrying cylinder and the transfer-cylinder, a suction-pipe, connections from said pipe to the grooves in the heads, an adjustable block in each groove for interrupting the communication between the channels and the grooves, and means for driving the transfer-cylinder at a varying speed which corresponds at times with the speed of each carrying-cylinder, substantially as described.

707,722. FUEL COMPOUND. JAMES H. RICKER, Fort Worth, Tex., assignor of two-thirds to Samuel Percival Greene and John Alfred Turney Evans, Fort Worth, Tex. Filed Feb. 8, 1902. Serial No. 93,197. (No specimens.)

Claim.—An artificial fuel consisting of the following thoroughly-associated ingredients, by volume, in about the proportions as follows: crude petroleum eighteen and three-fourths per cent., resin two and one-half per cent., sawdust twelve and one-half per cent., clay twelve and one-half per cent., liquid glass two and one-half per cent. and lignite or coal-dust fifty-one and one-fourth per cent.

707,723. COMBINATION-TOOL. FRANK A. ROBBINS, Worcester, Mass. Filed Jan. 20, 1902. Serial No. 90,291. (No model.)

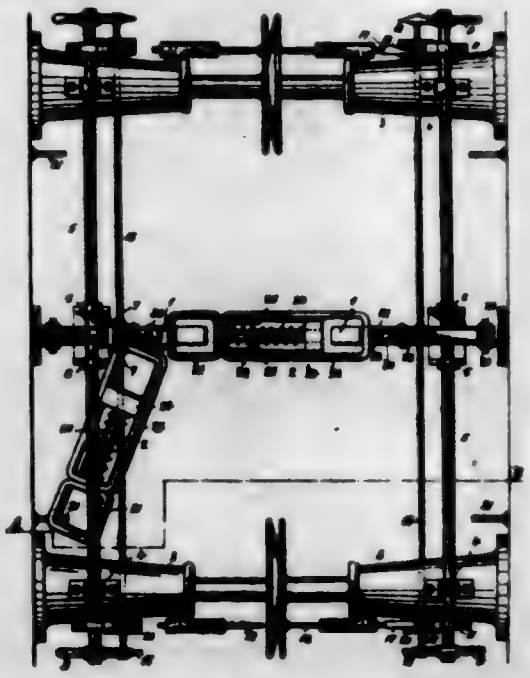
Claim.—1. A combined surface gage and beam-trammel, comprising in combination the rod A, base B, trammel C, the latter secured to the opposite end of said rod from said base, and carrying the compass-point *e* and adjustable caliper-leg *f*, and trammel D, the latter consisting of the slide-block *g'*, carrying the compass-point *e'* and adjustable caliper-leg *f'*, slide-block *j*, its set-screw *k* and adjusting-screw *i*, the latter fitted to turn in said slide-blocks *g'* and *j*, substantially as and for the purpose set forth.

2. Rod or beam A, trammel C, compass-point *e*, and caliper-leg *f*, said trammel consisting of block *g*, fitted and secured to said rod or beam, and having threaded hubs at right angles thereto, to receive and hold the threaded ends of said compass-point and caliper-leg, and means for locking them in position, in combination with the trammel D, compass-point *e'* and caliper-leg *f'*, said trammel consisting of block *g'*, fitted to slide on the rod or beam and having threaded hubs at right angles thereto, to receive and hold the threaded ends of said compass-point and caliper-leg, and means for locking the same, also having a threaded opening in one of the hubs parallel to the rod or beam to receive the adjusting-screw *i*; said trammel further consisting of the block *j*, also fitted to slide on rod or beam A, and having threaded hubs, one at right angles and the other parallel thereto, to receive respectively, the set-screw *k* and said adjusting-screw *i*, and said set and adjusting screws, substantially as and for the purpose set forth.

3. Rod or beam A, trammel C, compass-point *e* and caliper-leg *f*, said trammel consisting of block *g*, fitted and secured to said rod or beam and having threaded hubs at right angles thereto, to receive and hold the threaded ends of said compass-point and caliper-leg, and means for locking them in position, in combination with the trammel D, compass-point *e'* and caliper-leg *f'*, said trammel consisting of block *g'*, fitted to slide on the rod or beam and having threaded hubs at right angles thereto, to receive and hold the threaded ends of said compass-point and caliper-leg, and means for locking the same, also having a threaded opening in one of the hubs parallel to the rod or beam to receive the adjusting-screw *i*, and also having a hub g^4 and set-screw g^5, said trammel further consisting of the block *j*, also fitted to slide on rod or beam A and having threaded hubs, one at right angles and the other parallel thereto, to receive respectively the set-screw *k*, and said adjusting-screw *i*, and said set and adjusting screws, substantially as and for the purpose set forth.

4. The combination of rod or beam A, with trammel D, compass-point *e'*, and caliper-leg *f'*, said trammel consisting of block *g'*, fitted to slide on said rod or beam and having threaded hubs at right angles thereto, to receive and hold the threaded ends of said compass-point and caliper-leg, and means for locking the same, also having a threaded opening in one of the hubs parallel to the rod or beam to receive the adjusting-screw *i*, and also having a hub g^4 and set-screw g^5, said trammel further consisting of the block *j*, also fitted to slide on rod or beam A, and having threaded hubs, one at right angles, and the other parallel thereto, to receive respectively the set-screw *k*, and said adjusting-screw *i*, and said set and adjusting screws, substantially as and for the purpose set forth.

707,724. AUTOMATIC COUPLING FOR RAILWAY-CARS. ANDERS A. ROSENQVIST, Malmö, Sweden, assignor of one-half to Per Hansson, Dalköpings, Trollenberg, Sweden. Filed June 10, 1901. Serial No. 63,996. (No model.)



Claim.—1. In a car-coupler, the combination with a hook and a link one of said parts being rigid and the other pivoted, of means for elevating said pivoted part, pawl-and-ratchet devices for holding it raised, sliding rods designed to be operated by the buffer-heads, and adjustable members or arms connected to the pawls and designed to be adjusted or moved into or out of the path of the sliding rods, substantially as described.

2. In a car-coupler, the combination with a hook and a link, one of said parts being rigid and the other pivoted, of means for elevating said

pivoted part, pawl-and-ratchet devices for holding it raised, sliding rods designed to be operated by the buffer-heads, and adjustable members or arms connected to the pawls and designed to be adjusted or moved into or out of the path of the sliding rods and a transverse shaft carrying the adjustable members or arms whereby the arms at each side of the car may be simultaneously adjusted from one side of the car, substantially as described.

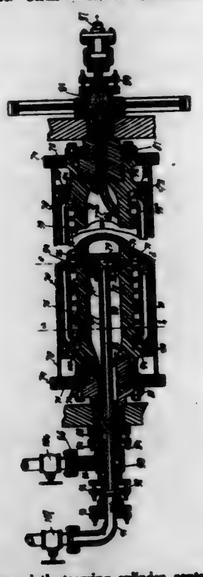
3. In a car-coupler, a hook carried by one car, a link carried by the other, one of said parts being pivoted, a rock-shaft having connections for operating said pivoted part, a ratchet device on said shaft, a pawl engaging said ratchet device, a second rock-shaft journaled in the ends of said pawls, contact-arms carried by said second shaft, and sliding rods arranged to partake of the movement of the buffers, said contact-arms being arranged to be thrown into or out of the paths of the sliding rods by the rotation of said second shaft, substantially as described.

4. In a car-coupler, a hook carried by one car, a link carried by the other, one of said parts being pivoted, a rock-shaft having connections for operating said pivoted part, a ratchet-wheel on said shaft, a pawl engaging said ratchet-wheel, a second rock-shaft journaled in the lower ends of said pawls, contact-arms carried by said second shaft, and sliding rods arranged to partake of the movement of the buffers, said contact-arms being arranged to be thrown into or out of the paths of the sliding rods, and lugs for supporting said arms in either position, substantially as described.

5. In a car-coupler, the combination with the pivotally-supported coupling-link having a transversely-hinging portion or shank 27, of a bow 32 for engaging the same for preventing transverse swinging, substantially as described.

6. In a hook-and-link car-coupler, the combination with the buffer-beam of a coupling-link, and a double link 29 pivotally connecting said link to said beam, substantially as described.

707,725. CLOTH-STEAMING MACHINE. ALEXANDER T. SARPERT, Chemnitz, Germany, assignor to David Gessner, Worcester, Mass. Filed Apr. 20, 1900. Serial No. 13,577. (No model.)



Claim.—1. In a cloth-steaming cylinder, containing a perforated shell, the combination within said shell, of a steam-discharger, a radiator, a water-shield surrounding the same and a perforated distributer whereby the steam from within said water-shield is distributed outside of the same, substantially as described.

2. In a cloth-steaming cylinder, in combination, a perforated shell, a steam-chambered radiator-casting upon which said shell is mounted and means whereby the steam for steaming is conducted through said casting, and means whereby said steam is confined in contact with the outer surface of said casting, substantially as described.

3. In a cloth-steaming machine, in combination, two steaming-cylinders, means for driving the same, a steam-pervious apron having its opposite ends secured to said steaming-cylinders, a presser intermediate said cylinders and mechanism whereby said presser may be moved toward either cylinder, substantially as described.

4. In a cloth-steaming machine, in combination a steaming-cylinder, an apron having one end secured on said steaming-cylinder, a cylinder on which the opposite end of said apron is secured, a presser in contact with which said apron travels between said cylinders and means whereby said presser is moved to or from said steaming-cylinder, substantially as described.

5. In a cloth-steaming cylinder, in combination, a perforated shell 70, a chambered body 72 containing a laterally-extending passage 71, a pipe 90 conveying the steaming-steam through a journal of the cylinder to said passage 71, a water-shield in the path of the steaming-steam between said passage 71 and the perforations of the shell and a pipe for conveying the heating-steam into said body, substantially as described.

6. In a cloth-steaming cylinder, in combination, a perforated shell 70, a chambered body 72 containing a laterally-extending passage 71, a pipe 90 conveying the steaming-steam through a journal of the cylinder to said passage 71, a water-shield in the path of the steaming-steam between said passage 71 and the perforations of the shell and a pipe for conveying the heating-steam into said body and heat-radiating members in the path of the steaming-steam between said passage 71 and the perforations of the shell, substantially as described.

7. In a cloth-steaming cylinder, in combination, a perforated shell 70, a body containing the chambers 77 and 77ª, respectively, at opposite ends thereof, means for supplying heating-steam to said chamber 77, a steam-passage from said chamber 77 to said chamber 77ª, an exit for the heating-steam from said chamber 77ª, a laterally-extending passage 71 located between said chambers and a pipe 90 for supplying the steaming-steam to said passage 71, substantially as described.

8. In a cloth-steaming machine, the combination of two steaming-cylinders adapted to receive the cloth thereon, and a pressing-cylinder, with swinging cylinder-supports whereby the pressing and steaming cylinders may have relative movement toward and from each other, substantially as described.

9. In a cloth-steaming machine, the combination of two steaming-cylinders adapted to receive the cloth thereon, and a pressing-cylinder, with swinging cylinder-supports whereby the pressing and steaming cylinders may have relative movement toward and from each other and a yielding power connection to said swinging supports, substantially as described.

10. In a cloth-steaming machine, the combination of two rotatable steaming-cylinders, a steam-pervious apron connected to both cylinders to be alternately wound thereon together with a piece of cloth, with a pressing-cylinder intermediate the steaming-cylinders, swinging supports for the journals thereof, and means for applying power to said pressing-cylinder to spring it toward either steaming-cylinder, substantially as described.

11. In a cloth-steaming machine, the combination of plural steaming-cylinders adapted to receive the cloth thereon, with a pressing-cylinder adapted to engage the cloth as wound upon each steaming-cylinder, guides for the journals of the pressing-cylinder, and means for moving said journals in said guides toward and from the steaming-cylinders, substantially as described.

12. In a cloth-steaming machine, the combination of two steaming-cylinders adapted to receive the cloth thereon, with a pressing-cylinder between the steaming-cylinders, guides for the journals of the pressing-cylinder adapted to permit the engagement of said cylinder with either steaming-cylinder and a power connection with said pressing-cylinder to move it in said guides, substantially as described.

13. In a cloth-steaming machine, the combination of two steaming-cylinders adapted to receive the cloth thereon, with a pressing-cylinder between the steaming-cylinders, guides for the journals of the pressing-cylinder adapted to permit the engagement of said cylinder with either steaming-cylinder, swinging yokes embracing the journals of the pressing-cylinder and extending transversely of said guides and means for swinging said yokes, substantially as described.

14. In a cloth-steaming machine, the combination of two steaming-cylinders adapted to receive the cloth thereon, with a pressing-cylinder between the steaming-cylinders, guides for the journals of the pressing-cylinder adapted to permit the engagement of said cylinder with either steaming-cylinder, swinging yokes embracing the journals of the pressing-cylinder and extending transversely of said guides, a segment-gear upon each yoke, gears engaging said segments and rotative power connections to said gears, substantially as described.

15. In a cloth-steaming cylinder, in combination, a perforated shell, a steam-chamber, an induction-passage into said steam-chamber, an eduction-passage from said steam-chamber, a steaming-steam passage leading to substantially the center of said cylinder and steaming-steam passages extending from the center to the periphery.

16. In a cloth-steaming cylinder, in combination, a perforated shell, two steam-chambers within the same, induction-passages to both of said chambers, an eduction-passage from one of said chambers discharging the steaming-steam within said shell and an eduction-passage from the other of said chambers discharging outside of said shell.

17. In a cloth-steaming cylinder, in combination, a perforated shell, a core provided with two longitudinal and induction steam-passages, a steam-chamber, a lateral passage connecting with said chamber.

18. In a cloth-steaming cylinder, in combination, a perforated shell, end journals, a core of greater diameter than said journals provided with a steam-chamber, means for supplying said chamber with steam and separate means for supplying said perforations with steam.

19. In a cloth-steaming cylinder, in combination, a perforated shell, end journals, a core having a steam-chamber of greater diameter than said journals, means for supplying said steam-chamber with steam and separate means for supplying said perforations with steam.

20. In a cloth-steaming cylinder, in combination, a perforated shell, means for supplying said perforations with steam and a core having a steam-chamber; the external diameter of said core exceeding two-thirds of the internal diameter of said shell whereby the requisite temperature of the steaming-steam may be maintained by the heat from said core until it reaches the perforations of said shell.

21. In a cloth-steaming cylinder, in combination, a perforated shell, means for supplying steam to said perforations and a core having a steam-chamber, the diameter of said steam-chamber exceeding one-third the internal diameter of said shell whereby a sufficient body of steam is maintained in said chamber to maintain the space within the shell at the requisite temperature for the steaming-steam.

22. In a cloth-steaming cylinder, in combination, a perforated shell, a core containing a steam-chamber, means for supplying heating-steam thereto and a steaming-steam passage extending along the chambered portion of said core.

23. In a cloth-steaming cylinder, in combination, a perforated shell, a core containing a steam-chamber extending substantially to both ends and a steaming-steam passage extending along a chambered portion of said core.

24. In a cloth-steaming cylinder, in combination, a perforated shell, a core provided with a steam-chamber, means for supplying heating-steam to said chamber and a steaming-steam passage extending through said chamber.

25. In a cloth-steaming cylinder, in combination, a perforated shell, a core provided with a steam-chamber, means for supplying heating-steam to said chamber, a steaming-steam passage extending through said core along a chambered portion thereof and thence out to the periphery thereof.

26. In a cloth-steaming cylinder, in combination, a perforated shell, a core provided with a steam-chamber, means for supplying heating-steam to said chamber and separate means for supplying steaming-steam to the interior of said shell.

27. In a cloth-steaming cylinder, in combination, a perforated shell provided with a steam-chamber near each end, a heating-steam supply passage leading into one of said chambers, a water-of-condensation passage leading from the other of said chambers, a steam-passage connecting the two chambers and means for supplying steaming-steam to the interior of said shell.

28. In a cloth-steaming cylinder, in combination, a perforated shell, a core containing adjoining induction-passages for the steaming-steam and heating-steam, respectively, a passage by which said heating-steam is conducted around said steaming-steam after leaving said induction-passage.

29. In a cloth-steaming cylinder, in combination, a perforated shell, a steaming-steam chamber located a substantial distance within the end of the cylinder, a passage whereby heating-steam is conducted outside of and in contact with the walls of said chamber and means whereby said chamber is supplied with steaming-steam.

30. In a cloth-steaming cylinder in combination, a perforated shell, a core or drum therein containing separate chambers for the reception of the heating-steam and the steaming-steam, said chambers being designed for the transfer of heat from the heating-steam to the steaming-steam.

31. In a cloth-steaming cylinder, in combination, a perforated shell, a steam-chambered heater within the same provided with a longitudinal depression in its exterior surface and a steaming-steam passage in said depression.

32. In a cloth-steaming cylinder, in combination, a perforated shell, a steam-chambered heater within the same, a steaming-steam-distributing pipe between it and said perforated shell, a nozzle projecting from said pipe nearer the center than parts of greatest diameter of said heater whereby the water is trapped substantially within the field of said heater and an induction steaming-steam-supply pipe.

33. A cloth-steaming-cylinder core containing, in combination, the heating-steam chambers 77 and 77ª adjacent to opposite ends, a passage 77ª connecting the same, a laterally-extending steaming-steam passage intermediate said end chambers and an induction-passage to said lateral passage.

34. A cloth-steaming-cylinder core containing, in combination, the heating-steam chambers 77 and 77ª adjacent to opposite ends, a laterally-extending steaming-steam passage intermediate said end chambers and an induction-passage to said lateral passage.

35. A cloth-steaming-cylinder core containing, in combination, the heating-steam chambers 77 and 77ª adjacent to opposite ends, a laterally-extending steaming-steam passage intermediate said end chambers and an induction-passage to said lateral passage; said induction-passage passing through one of said end chambers.

36. A cloth-steaming-cylinder core containing, in combination, the end heating-steam chambers 77, 77ª, a steaming-steam chamber 79 intermediate the same, a passage from said chamber 79 to the periphery and an induction-passage to said chamber 79.

37. A cloth-steaming-cylinder core, containing in combination, the end heating-steam chambers 77 and 77ª, an intermediate laterally-extending steaming-steam passage, a steaming-steam induction-passage and means whereby water is trapped in passing laterally outward from said induction-passage.

38. In a cloth-steaming cylinder, in combination, a perforated exterior shell, a core containing the end heating-steam chambers 77 and 77ª and a laterally-extending steaming-steam passage intermediate the same, an induction-passage to said intermediate passage and a trap for holding back the water of condensation as the heating-steam passes from said induction-passage to said perforated shell.

39. In a cloth-steaming cylinder, in combination, a perforated exterior shell, a rotating core carrying the same and provided with journals and with the end heating-steam chambers 77 and 77ª and with an intermediate laterally-extending steaming-steam passage, induction heating-steam and steaming-steam passages through one of said journals and an eduction-passage from said heating-steam chamber through the other of said journals.

40. In a cloth-steaming cylinder, the combination with an outer perforated cylinder, of an inner heating-core having therein distinct chambers for the reception of the heating and the steaming steam, means for discharging the steaming-steam from its chamber into the perforated cylinder and means for separately supplying each chamber with its steam.

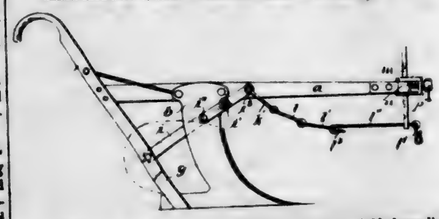
41. In a cloth-steaming cylinder, the combination with an outer perforated cylinder, of an inner heated core having therein distinct chambers for the reception, respectively, of the heating and steaming steam, means provided with a water-trap for discharging the steaming-steam from its chamber into the perforated cylinder and means for supplying each chamber with its steam.

42. In a cloth-steaming cylinder, in combination, a perforated shell, a heating-core containing a heating-steam chamber and a laterally-extending steaming-steam passage, an induction-passage to said lateral passage and a longitudinally-extending perforated distributer whereby the steam is distributed outside of said core.

43. In a cloth-steaming cylinder, in combination, a perforated shell, a heating-core containing a steaming-steam chamber and a laterally-extending steaming-steam passage, an induction-passage to said lateral passage, a longitudinally-extending distributer between said core and said perforated cylinder and means whereby the water is trapped as said steam passes from said induction-passage to said longitudinal distributer.

44. In a cloth-steaming cylinder, in combination, a perforated shell, a heating-core containing a heating-steam chamber, means whereby the steaming-steam is conducted through said core and means whereby said steaming-steam is caused to flow against the surface of said heating-core.

707,726. PLOW. ADOLPH SCHULZ, Chicago, Ill. Original application filed Sept. 3, 1901, Serial No. 74,208. Divided and this application filed Feb. 7, 1902. Serial No. 93,070. (No model.)



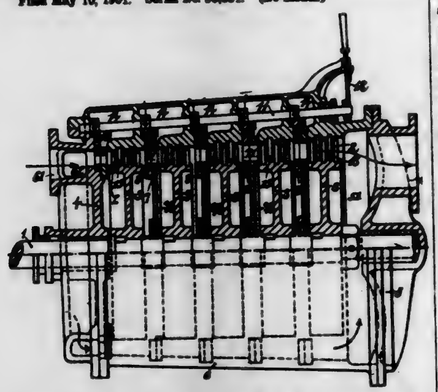
Claim.—1. In a plow, in combination, a beam, a rigid depending standard, a plow secured to the standard, braces arranged on opposite sides of and secured to the standard and extending upwardly and forwardly there-

from with their front ends on opposite sides of the beam, a swinging clevis, a bolt passing transversely through the beam, braces and clevis and securing the braces and clevis to the beam, an adjustable support at the front end of the beam, and a draft connection passing loosely through said support and at its rear end secured to said clevis and having draft-attaching means at its front end, substantially as described.

2. In a plow in combination, a beam, a depending standard, a plow secured thereto, handles, two inclined braces on opposite sides of and secured to the beam, one of said braces extended rearwardly and secured to a handle, the two braces extending forwardly on opposite sides of the beam, a support at the front end of the beam, a draft connection passing through said support, a cross-bolt passing through the beam and said braces and confining the rear end of said connection to the beam and front ends of the braces, said connection including rods, one having an open link or eye and another a hook detachably engaging said eye, substantially as described.

3. A plow-beam having a rigid transversely-elongated loop at its front end, in combination with a U-shaped clip fitting above and below said loop and adjustable horizontally thereon and having vertical openings in its horizontal portions above and below the loop-opening, a screw passing through the front end of the clip into engagement with the front side of the loop, the vertical bar passing through said loop and clip-openings and having the vertical series of transverse notches in its rear face to receive the edges of the clip, said bar having a guide at its lower portion, and a draft connection secured to the beam and extending forwardly beneath the beam and through said guide, the parts operating, substantially as described.

707,727. STEAM-TURBINE. RICHARD SCHULZ, Berlin, Germany. Filed May 10, 1901. Serial No. 59,661. (No model.)



Claim.—1. In a turbine, the combination with a ring-shaped valve-seat provided with ports, of a ring-valve having ports successively decreasing in area and coöperating with these in the seat, and means for rotating both valve and seat, substantially as described.

2. In a turbine, the combination with a ring-shaped valve-seat provided with ports, of a ring-shaped valve having ports successively decreasing in area and coöperating with these in the seat, and means for rotating both valve and seat in opposite directions, substantially as described.

3. In a steam-turbine, the combination with a valve-seat having equidistant ports therethrough, said ports larger at their entering than at their delivery side, of a ring-valve, divided into a suitable number of divisions and provided with a number of ports in each division, the ports in each division successively decreasing in area, substantially as described.

4. In combination, an annular valve-seat provided with ports, a ring-valve coöperating therewith, the ports through said valve in each quadrant successively wider, substantially as described.

5. In combination, an annular valve-seat provided with ports equidistant from one another and larger at their entering than at their delivery side, and a ring-valve whose ports in each quadrant are successively larger, substantially as described.

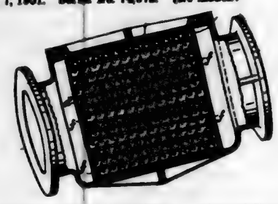
6. In combination, a valve-seat provided with ports equidistant from one another and a valve provided with ports on its periphery, the ports in each quadrant successively larger, both valve and seat organized to be rotated, substantially as described.

7. In a steam-turbine, in combination with the several turbine-wheels, of partitions separating the several wheels and provided with valve-seats, said partitions independently rotatable and a series of ring-valves coöperating with said seats and each provided with gear-teeth, and pinions arranged on a common shaft gearing with the respective valves to simultaneously move an equal extent, substantially as described.

8. In a turbine, the combination with a plurality of wheels, of partitions independently rotatable and a rod pivoted to each partition and extending through the casing of said turbine, a series of ports arranged in said partitions to form valve-seats, ring-valves coöperating with said seats and means for simultaneously moving said valves, substantially as described.

9. In a turbine, the combination with a tubular ring-shaped valve-seat, of a tubular ring-shaped valve coöperating therewith, both having ports arranged in their peripheries and each adjustable with respect to the other, substantially as described.

707,728. OIL-SEPARATOR. RICHARD SCHULZ, Berlin, Germany. Filed Sept. 7, 1901. Serial No. 74,672. (No model.)



Claim.—An oil-separator, comprising a substantially rectangular chamber adapted to be inserted in a steam-conduit so that its longitudinal axis will be inclined thereto, vertical plates therein, straight ribs on said plates inclined in the direction of the entering steam and extending from top to bottom of said chamber, the ribs of adjacent plates overlapping to direct steam in thin sheets in a zigzag manner along opposite sides of the plates and from end to end of said chamber and to deposit oil in the re-entrant angles formed by said ribs, an entering and exit union to said chamber, the latter above the inclined bottom of the chamber, and means to draw off the separated oil below said union and from between the plates, substantially as set forth.

707,729. APPARATUS FOR TEACHING GUN PRACTICE. CARL A. STORNOW, Stockholm, Sweden, assignor, by mesne assignments, to Ernst Lundgren and Alfred Richardson, Brooklyn, N. Y., and James Whitcomb, New York, N. Y. Filed Sept. 4, 1901. Serial No. 74,297. (No model.)

Claim.—1. The combination of the gun-support adapted for the application of a gun for use in connection with it, as in sighting the gun and shooting, and provided with a trigger for use in lieu of the gun-trigger, the universally-jointed mounting of said support, a pointer having a universally-jointed support, and connected with the gun-support so as to maintain parallelism with the deviating line of the gun-sight, a ball's-eye mark located in the line which the pointer occupies when the gun is truly sighted with relation to the object aimed at, an automatic clamp to lock the parts in the positions occupied when the trigger is pulled, setting devices for holding the clamp in readiness for action, and tripping mechanism for said holding devices actuated by the trigger.

2. The combination of the gun-support adapted for the application of a gun for use in connection with it, as in sighting the gun and shooting, and provided with a trigger for use in lieu of the gun-trigger, the universally-jointed mounting of said support, a pointer having a universally-jointed support, and connected with the gun-support so as to maintain parallelism with the deviating line of the gun-sight, a ball's-eye mark

located in the line which the pointer occupies when the gun is truly sighted with relation to the object aimed at, and having a transparent support, an automatic clamp to lock the parts in the positions occupied when the trigger is pulled, setting devices for holding the clamp in readiness for action, and tripping mechanism for said holding devices actuated by the trigger.

3. The combination of the gun-support, trigger connected with said support, universally-jointed mounting of said support, a pointer having a universally-jointed support, and connected with the gun-support so as to maintain parallelism with the deviating line of the gun-sight, automatic locking-clamp for said support, setting devices for holding said clamp in readiness for action, tripping-lever of said setting devices, tripping-lever-actuating rod carried in the gun-support-mounting devices, the arm of the trigger adapted to actuate said rod, and means to retire the rod.

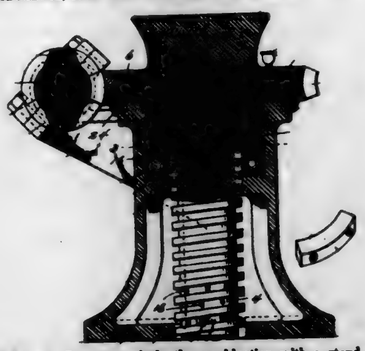
4. The combination of the gun-support, trigger connected with said support, universally-jointed mounting of said support, a pointer having a universally-jointed support, and connected with the gun-support so as to maintain parallelism with the deviating line of the gun-sight, automatic locking-clamp for said support, means for releasing said clamp, setting devices for holding said clamp in readiness for action, tripping-lever of said setting devices, tripping-lever-actuating rod carried in the gun-support-mounting devices, the arm of the trigger adapted to actuate said rod, and means to retire the rod.

5. The combination of the gun-support and its standard, the block and the step-support carrying the standard, bearings carrying the block-pivots and adapted to clamp the block, clamping-sleeve and bolts connecting said sleeve and bearings, clamping-screw, screw-actuating lever and spring, the screw setting and tripping devices, the trigger of the gun-support adapted for actuating the tripping devices and a pointer having a universally-jointed support, and connected with the gun-support so as to maintain parallelism with the deviating line of the gun-sight.

6. The combination with the universal-joint-supported gun-support which is subject to direct manipulations of the operator in firing the gun, of the universal-joint-supported pointer, means connecting the gun-support and pointer whereby parallelism of the pointer with the deviating line of the gun-sight results from the deviations of the gun and a substitute bull's-eye mark in close proximity to the pointer.

7. The combination with the universal-joint-supported gun-support, the universal-joint-supported pointer, and means connecting the gun-support and pointer whereby parallelism of the pointer is maintained with the deviating line of the gun-sight, of the bull's-eye mark located in the line which the pointer occupies when the gun is truly sighted with relation to the object aimed at, and an adjustable mirror adapted for reflecting the images of the pointer and the bull's-eye into the visual range of the instructor in the requisite proximity to the operator for directing him.

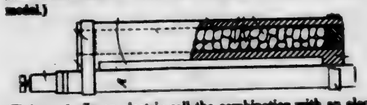
707,730. SCREW-JACK. CHARLES F. STONER, Wilmington, Del. Filed June 12, 1902. Serial No. 111,276. (No model.)



Claim.—1. In a screw-jack, the combination with a stand, of a worm-wheel mounted thereon, a worm meshing with the worm-wheel, a screw-post extending centrally through the worm-wheel and provided between the threads thereof with a series of holes, and an adjustable segmental step fitting between the threads of the screw-post and held in place by fasteners adapted to engage the holes between the threads, substantially as described.

2. In a screw-jack, the combination with a stand, of a worm-wheel mounted thereon, a worm meshing with the worm-wheel, a screw-post passing centrally through the worm-wheel and having a threaded engagement therewith, and a segmental step adjustably mounted between the threads of the screw-post, substantially as set forth.

707,731. ELECTRIC BATTERY. ERNEST A. G. STRIEBY, Paris, France, assignor to Société Anonyme le Carbone, Levallois-Perret, near Paris, France. Filed Apr. 22, 1902. Serial No. 104,194. (No model.)



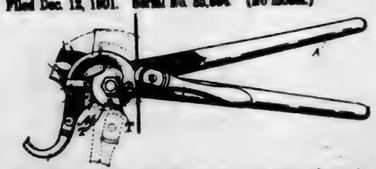
Claim.—1. In an electric cell the combination with an electrode of a receptacle containing depolarizing material and connected directly to said electrode but having a recess on the side adjacent to the electrode, said recess being freely open to the electrolyte, and means for detachably securing said receptacle to the electrode, substantially as described.

2. In an electric cell the combination with an electrode, of a terminal connected directly to the electrode, a permeable receptacle composed of the same or a similar material to that of the electrode, depolarizing material in said receptacle, and elastic bands for detachably securing said receptacle to the electrode, substantially as described.

3. In an electric cell the combination with the carbon electrode of a porous carbon receptacle, depolarizing material in said receptacle, and elastic bands adapted to detachably secure said receptacle to the electrode, substantially as described.

4. In an electric cell, the combination with the carbon electrode of a porous carbon receptacle, lugs on said receptacle adapted to abut against the electrode, a filling of depolarizing material in said receptacle and elastic bands for detachably securing said receptacle to said electrode, substantially as described.

707,732. WIRE-STRETCHER. ERNST R. SWARD, Calamus, Iowa, assignor to the Sward Fence Builder Tool Company, Davenport, Iowa. Filed Dec. 12, 1901. Serial No. 85,664. (No model.)



Claim.—1. A wire-stretching tool, comprising a lever A, a hook pivoted to the head of said lever, ratchet-teeth on the face of the lever adjacent to its pivotal point, a second lever pivoted to the hook-carrying lever, having a face in contact with said ratchet-teeth, clamping means for holding the wire to be stretched, a pawl carried by said second lever and adapted to engage the ratchet-teeth of the hook-carrying lever, as set forth.

2. A wire-stretching tool, comprising two levers pivoted together, one of said levers having ratchet-teeth on its face, which is in contact with the face of the second lever, a spring-actuated pawl pivoted to the second lever, and engaging said ratchet-teeth, a curved and grooved segment, secured to, or integral with the pawl-carrying lever, and a pivoted lever, having serrated jaw and adapted to coöperate with the curved end of said segment, to hold a wire while being stretched, as set forth.

707,733. CORN-PLANTER. WILLIAM F. TALBERT, Frankstown, Md. Filed June 18, 1902. Serial No. 112,266. (No model.)

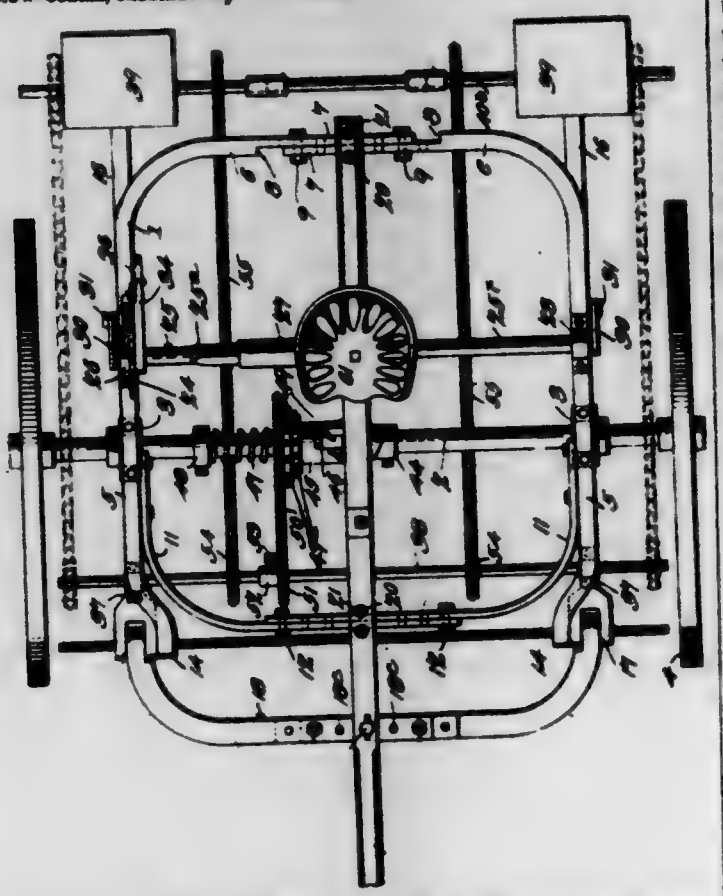
Claim.—1. In a machine of the class described, the upper frame composed of side members having inwardly-bent and overlapping rear ends, downwardly and inwardly curved front ends, brackets secured to the inner sides of said side members and having inwardly-bent overlapping ends and suitable connecting means, substantially as set forth.

2. In a machine of the class described, the upper frame composed of side members having overlapping rear ends, brackets secured to said side members and having overlapping ends, the tongue supported upon the overlapping parts of the frame, and clips embracing the latter and connecting them to the tongue, substantially as set forth.

3. In a machine of the class described, the upper frame composed of separable side members, laterally adjustable with relation to each other, the tongue supported upon said frame, clips engaging the overlapping members of the latter and connecting them with the tongue and a lower frame having pivotal connection with the downwardly and inwardly curved side members of the upper frame by a transverse connecting-rod, substantially as set forth.

4. In a machine of the class described, the upper frame having side members laterally adjustable with relation to each other and provided with downwardly-curved front ends, a transverse connecting-rod extending through said ends, plow-beams having bifurcated, transversely-perforated front ends engaging said connecting-rod, and a yoke composed of separa-

ble and adjustable members, transversely perforated at their ends and engaging the transverse connecting-rod and the bifurcated front ends of the plow-beams, substantially as set forth.



5. In a machine of the class described, the combination of an upper frame composed of separable and relatively adjustable side members, a tongue supported upon said frame and having clips embracing the overlapping members thereof, a transverse connecting-rod extending through perforations at the front ends of the downwardly-curved side members of the upper frame, the plow-beams having bifurcated and transversely-perforated front ends pivotally engaging said connecting-rod, a yoke composed of separable, relatively adjustable members having transversely-perforated ends engaging the connecting-rod and the bifurcated front ends of the plow-beams, a connecting rod or bolt forming a vertical connection between the yoke and the tongue of the machine, and a bracket mounted upon said bolt and having a transverse perforation engaging the transverse connecting-rod, substantially as set forth.

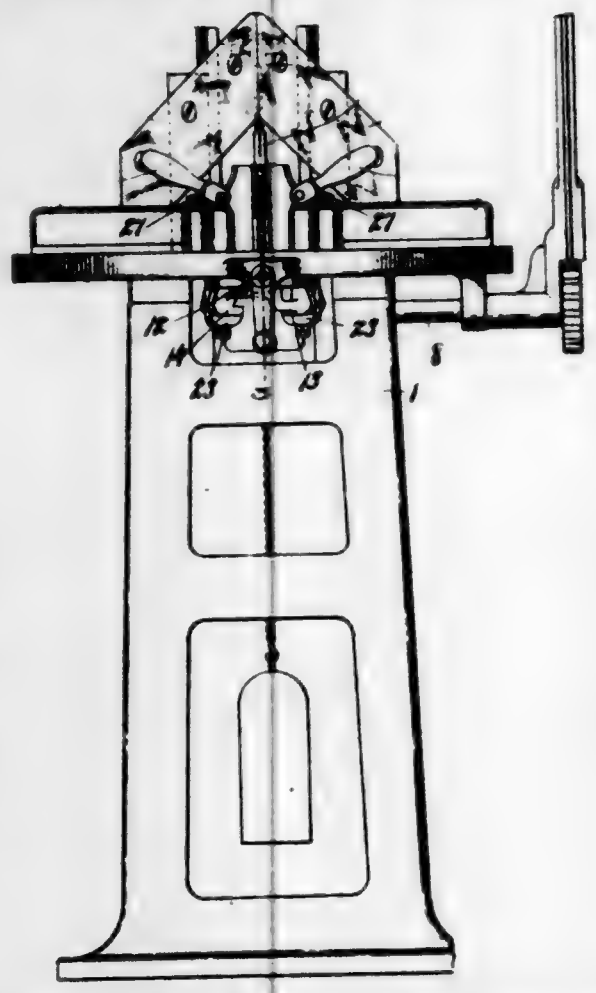
6. In a machine of the class described, the combination of an upper frame composed of separable and relatively adjustable side members, a tongue supported upon said frame and having clips embracing the overlapping members thereof, a transverse connecting-rod extending through perforations at the front ends of the downwardly-curved side members of the upper frame, the plow-beams having bifurcated and transversely-perforated front ends pivotally engaging said connecting-rod, a yoke composed of separable relatively adjustable members having transversely-perforated ends engaging the connecting-rod and the bifurcated front ends of the plow-beams, a vertical bolt forming a connection between the yoke and the tongue of the machine, and a spring coiled upon said bolt to space said tongue and yoke apart, substantially as set forth.

7. In a machine of the class described, the combination of a frame composed of separable and relatively adjustable side members, connecting means for the overlapping ends of said side members, an axle journaled in boxes attached to the side members of said frame and having supporting-wheels thereon, plow-beams having pivotal connection with the depending front ends of the side members of said frame, seeding mechanism supported at the rear ends of said plow-beams, a transverse shaft journaled in boxes near the front ends of the plow-beams, and means for transmitting motion between said shaft and the axle and between said shaft and the seeding mechanism, substantially as set forth.

8. In a machine of the class described, the upper frame composed of relatively adjustable side members having overlapping parts, a tongue supported upon said overlapping parts and having clips embracing the same, plow-beams having pivotal connection with said upper frame, a yoke composed of separable, relatively adjustable members connecting the front ends of said plow-beams, a shaft supported upon the side members of the upper frame and composed of two members slidably connected, cranks at the ends of said shaft, suitable connections between said cranks and the plow-beams, and means for operating the crank-shaft, substantially as set forth.

9. In a machine of the class described, the combination of an upper frame composed of separable relatively adjustable side members, a wheeled axle supporting said frame, plow-beams having pivotal connection with said frame, a transverse shaft supported in bearings upon the plow-beams near their front ends, seed-hoppers supported upon said plow-beams near their rear ends, a transverse shaft journaled in said hoppers, said shaft being composed of three members connected at their meeting ends by couplings which permit them to revolve independently of each other, means for transmitting motion between the end sections of said shaft and the transverse shaft supported at the front ends of the plow-beams, means for transmitting motion between the latter shaft and a clutch-sleeve mounted slidably upon the axle of the machine, and means for operating said clutch-sleeve to throw the latter into or out of engagement with a fixed clutch member upon the axle, substantially as set forth.

707,734. MITERING-MACHINE. JOSEPH L. TYLER, Lynn, Mass. Filed Oct. 16, 1901. Serial No. 78,789. (No model.)



Claim.—1. In a mitering or similar machine, a cutter, a gage-support having an aperture, and a gage structure pivoted to assume different angles with respect to the cutter and comprising a gage mounted above the support, an arm mounted below the support and connected with the gage through said aperture, said arm having a hub portion pivoted to the support and constituting a clamping member, a pivotal bearing for said hub portion on the support constituting a complemental clamping member, and clamp-operating means to vary the pressure between said clamping members.

2. In a mitering or similar machine, a cutter, a gage-support having an aperture, and a gage structure mounted on said support and comprising a gage above the support, an arm below the support having a pivotal bearing on the support and constituting a clamping member, a telescopic connection between the gage and arm extending through said aperture and constructed to permit relative vertical movement but to prevent relative rotary movement of the gage and arm, and clamp-operating means to vary the pressure between said arm and gage and the support.

3. In a mitering or similar machine, a cutter, a gage-support having an aperture, and a gage structure pivoted to said support and adapted to assume different angles with respect to the cutter, said structure comprising a gage above the support, a clamping member below the support, a telescopic connection between said gage and clamping member extending through said aperture, a washer having both a vertical sliding bearing and a horizontal bearing on the clamping member, a clamp-operating stem extending through the telescopic connection and engaging the washer, and means to impart a longitudinal movement to said stem.

4. In a mitering or similar machine, a gage-support, and two gage structures provided with arms having pivotal bearings on said support lo-

united in substantially the same plane one outside of the other, the arm with the inner bearing being offset to pass around the outer bearing.

5. In a mitering-machine, a work-supporting table, a cutter-head having a knife operating across the inner edge of the table, and a back-gage structure mounted upon the cutter-head and comprising a vertical stem, a gage-arm thereon having a gage portion movable toward and from the table edge by rotation of the stem, and oppositely-directed adjustable stop devices adapted to limit the rotary movement of said stem in both directions.

707,785. FLUID-PRESSURE-OPERATED TOOL. HENRY H. VAUGHAN, Chicago, Ill., assignor to Ridgely and Johnson Tool Company, a Corporation of Illinois. Filed July 3, 1901. Serial No. 66,948. (No model.)

Claim.—1. In a fluid-pressure-operated tool, the combination with a cylinder, of a reciprocating piston therein, a die movably fitted in the end of said cylinder, yielding means for retaining said die within the end of the cylinder, and means for automatically removing the die from the path of the piston to prevent the ejectment of the die from the cylinder by a blow from the piston, substantially as described.

2. In a fluid-pressure-operated tool, the combination with a cylinder, of a reciprocating piston therein, a die movably fitted in the end of said cylinder, yielding means for retaining said die within the end of the cylinder, a shoulder extending into the cylinder to limit the throw of the piston, and means for withdrawing the die from the path of the piston, to prevent the ejectment of the die from the cylinder by a blow from the piston, substantially as described.

3. In a fluid-pressure-operated tool, the combination with a cylinder, of a reciprocating piston therein, a die movably fitted in said cylinder, yielding means for retaining said die within the end of the cylinder, a shoulder extending into the cylinder to limit the throw of the piston, and a spring-actuated collar engaging said die and withdrawing the same from the path of the piston to prevent the ejectment of the die from the cylinder by a blow from the piston, substantially as described.

4. In a fluid-pressure-operated tool, the combination with a cylinder having ports therethrough, of a reciprocating piston in said cylinder, a die movably fitted in said cylinder, and a spring-actuated collar closing said ports through the cylinder when the die is forced against an object, and uncovering said ports when the die is not in contact with an object, substantially as described.

5. In a fluid-pressure-operated tool, the combination with a cylinder having ports therethrough, of a reciprocating piston in said cylinder, a die movably fitted in said cylinder, a spring-actuated collar surrounding the end of said cylinder and engaging said die, said collar being moved so as to cover said ports when the die is forced against an object and being moved by spring-pressure to uncover said ports when the die is not in contact with an object, substantially as described.

6. In a fluid-pressure-operated tool, the combination with a cylinder having ports therethrough, of a reciprocating piston in said cylinder, a die movably fitted in said cylinder, a collar surrounding the end of said cylinder and engaging said die, a spring interposed between said cylinder and collar whereby the die when forced against an object compresses said spring and moves said collar over the ports and when the die is disengaged from an object said spring expands and thereby moves said collar to uncover the ports, substantially as described.

7. In a fluid-pressure-operated tool, the combination with a cylinder having ports therethrough, a reciprocating piston in said cylinder, a shoulder extending into said cylinder to limit the throw of the piston, a die movably fitted in said cylinder, a collar controlling said ports and engaging said die, and a spring interposed between the cylinder and collar, substantially as described.

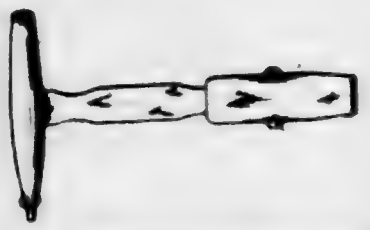
8. In a fluid-pressure-operated tool, the combination with a cylinder having an exhaust-port therethrough, of a reciprocating piston in said cylinder, and automatic means for closing and opening said exhaust-port when the tool is respectively pressed against and out of contact with an object, substantially as described.

9. In a fluid-pressure-operated tool, the combination with a cylinder having ports therethrough, of a reciprocating piston therein, a die movably fitted in said cylinder, and a spring-actuated collar closing said ports through the cylinder when the die is pressed against an object, and uncovering said ports and withdrawing said die from the path of the piston when the die is not in contact with an object, substantially as described.

10. In a fluid-pressure-operated tool, the combination with a cylinder having ports therethrough, of a reciprocating piston in said cylinder, a die movably fitted in said cylinder, a collar surrounding the end of said cylinder and engaging said die, a spring interposed between said cylinder and collar whereby the die when forced against an object compresses said spring and moves said collar over the ports and when the die is disengaged from an object said spring expands and thereby moves said collar to uncover the ports and coincidentally withdraws the die from the path of the piston, substantially as described.

11. In a fluid-pressure-operated tool, the combination with a cylinder, of a reciprocating piston therein, a die movably fitted in the end of said cylinder and yieldingly retained therein, and means for automatically moving the die out of the range of impact of the piston to prevent its ejectment from the cylinder by the piston.

707,786. GARMENT-SUPPORTER. WILLIAM G. WALTON and DANIEL W. HARNER, Philadelphia, Pa., assignors of one-third to Elias W. Evans, West Philadelphia, Pa. Filed Mar. 4, 1902. Serial No. 96,583. (No model.)



Claim.—1. A garment-supporter, comprising two fastening devices united in an integral structure by a flat oblong flexible strip, said fastening devices projecting respectively from opposite faces of said strip, and one of said devices consisting of a spring-clip, comprising two spring-controlled jaws and the other device consisting of a safety-clasp, comprising a rigid bar having a pin adapted to engage and to be disengaged from the rear face of said bar, substantially as described.

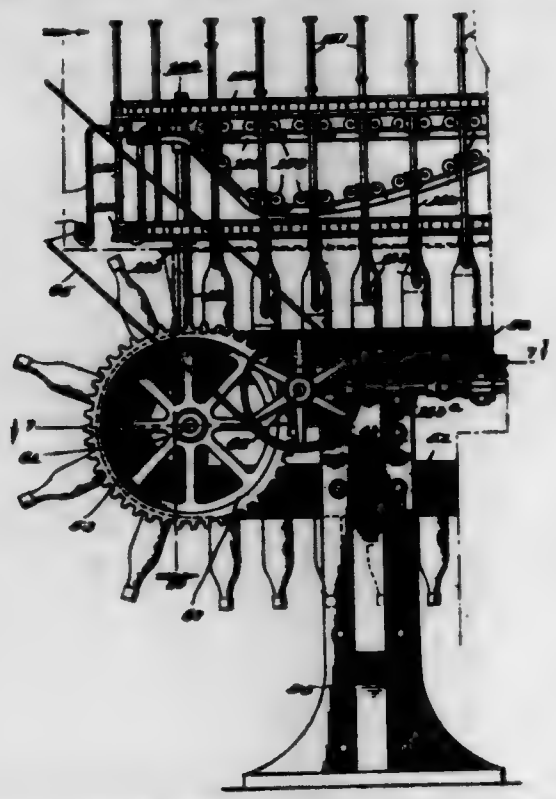
2. A garment-supporter, comprising two fastening devices, whereof one has a solid face with a transversely-arranged fastening-pin and whereof the other has a fixed face and a spring-controlled movable jaw, a long, narrow and flexible strip formed integral with the solid face of one of said fasteners and integral with the fixed jaw of the other of said fasteners and the operative members of said fastening devices projecting from opposite faces of said strip, substantially as described.

707,787. BOTTLING-MACHINE. CLINTON J. WARREN, Chicago, Ill. Filed May 16, 1901. Serial No. 60,594. (No model.)

Claim.—1. The combination with an endless carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for moving said carrier, devices for successively operating to clean said bottles, fill the same, insert corks in the bottle-necks, and wire said corks in place, means for causing said devices to engage said bottles and while so engaged to be moved a limited distance with the bottles, devices for applying labels to said bottles, and means for operating said various devices, substantially as specified.

2. The combination with an endless carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for moving said carrier, devices for successively operating to clean said bottles,

fill the same, insert corks in the bottle-necks, and wire said corks in place, means for causing said devices to engage said bottles and while so engaged to be moved for a limited distance with the bottles, means for withdrawing said devices in a direction opposite to the movement of the carrier, devices for applying labels to said bottles, and means for operating said various devices, substantially as specified.



3. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices adapted to operate simultaneously upon different bottles on the carrier and acting to clean, fill and cork the bottles, and wire the corks in place, means for causing said devices to travel for a limited distance in engagement with the bottles, devices for applying labels to said bottles, and means for operating said various devices simultaneously, substantially as specified.

4. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices adapted to operate simultaneously upon different bottles on the carrier and acting to clean, fill and cork the bottles, and wire the corks in place, means for causing said devices to travel for a limited distance in engagement with the bottles, means for withdrawing said devices in a direction opposite to the movement of the carrier, devices for applying labels to said bottles, and means for operating said label-applying devices simultaneously with the operation of the said other devices, substantially as specified.

5. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, a series of devices each adapted to perform a different function and to operate simultaneously on different bottles on the carrier, means for causing said devices to travel a limited distance in engagement with the bottles, means for operating such devices while they are traveling in engagement with said bottles, and means for withdrawing said devices in a direction opposite to the movement of the carrier, substantially as specified.

6. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for washing said bottles, means for causing said devices to travel for a limited distance in engagement with the bottles, means for operating said devices while they are traveling in engagement with said bottles, other devices for operating on said bottles after being washed, means for causing said second-named operating devices to also travel for a limited distance in engagement with the bottles, and means for operating them while so engaged, substantially as specified.

7. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for washing said bottles, devices for filling said bottles after they have been washed, means for causing said washing and filling devices to travel for a limited distance in engagement with the bottles, and means for operating such devices while they are traveling in engagement with the bottles, substantially as specified.

8. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for washing said bottles, devices for filling said bottles after they have been washed, means for causing said washing and filling devices to travel for a limited distance in engagement with the bottles, means for operating such devices while they are traveling in engagement with the bottles, and means for withdrawing said devices in a direction opposite to the movement of the carrier, substantially as specified.

9. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for washing said bottles, devices for filling said bottles after they have been washed, devices for corking the said bottles after they have been filled, means for causing said washing, filling and corking devices to travel for a limited distance in engagement with the bottles, and means for operating such devices while they are traveling in engagement with the bottles, substantially as described.

10. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for washing said bottles, devices for filling said bottles after they have been washed, devices for corking the said bottles after they have been filled, means for causing said washing, filling and corking devices to travel for a limited distance in engagement with the bottles, means for operating such devices while they are traveling in engagement with the bottles, and means for withdrawing such devices in a direction opposite to the movement of the carrier, substantially as described.

11. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for filling said bottles, devices for corking said bottles after they have been filled, means for causing said filling and corking devices to travel for a limited distance in engagement with the bottles, means for operating such devices while they are traveling in engagement with the bottles, and means for withdrawing said devices in a direction opposite to the movement of the carrier, substantially as described.

12. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for filling said bottles, devices for corking said bottles after they have been filled, devices for wiring said bottles after they have been corked, means for causing said filling, corking and wiring devices to travel for a limited distance in engagement with the bottles, and means for operating said devices while they are traveling in engagement with the bottles, substantially as described.

13. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for filling said bottles, devices for corking said bottles after they have been filled, devices for wiring said bottles after they have been corked, means for causing said filling, corking and wiring devices to travel for a limited distance in engagement with the bottles, means for operating said devices while they are traveling in engagement with the bottles, and means for withdrawing said devices in a direction opposite to the movement of the carrier, substantially as described.

14. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for filling said bottles, devices for corking said bottles after they have been filled, devices for wiring the bottles after they have been corked, means for causing the said devices to travel for a limited distance in engagement with the bottles, means for operating such devices while they are traveling in engagement with the bottles, devices for applying labels to the bottles after they have been wired, and means for operating said labeling devices, substantially as specified.

15. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for filling said bottles, devices for corking said bottles after they have been filled, devices for wiring the bottles after they have been corked, means for causing the said devices to travel for a limited distance in engagement with the bottles, means for operating such devices while they are traveling in engagement with the bottles, means for withdrawing said devices in a direction opposite to the movement of the carrier, devices for applying labels to the bottles after they have been wired, and means for operating said labeling devices, substantially as specified.

16. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for washing said bottles, devices for filling said bottles after they have been washed, devices for corking said bottles after they have been filled, devices for wiring said bottles after they have been corked, means for causing said washing, filling, corking and wiring devices to travel for a limited distance in engagement with the bottles, and means for operating said devices while they are traveling in engagement with the bottles, substantially as described.

17. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for washing said bottles, devices for filling

said bottles after they have been washed, devices for corking said bottles after they have been filled, devices for wiring said bottles after they have been corked, means for causing said washing, filling, corking and wiring devices to travel for a limited distance in engagement with the bottles, means for operating said devices while they are traveling in engagement with the bottles, and means for withdrawing said devices in a direction opposite to the movement of the carrier, substantially as described.

18. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for washing said bottles, devices for filling said bottles after they have been washed, devices for corking said bottles after they have been filled, devices for wiring said bottles after they have been corked, means for causing the said devices to travel for a limited distance in engagement with the bottles, means for operating said devices while they are traveling in engagement with the bottles, devices for applying labels to said bottles after they have been wired, and means for operating the said labeling devices, substantially as specified.

19. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for washing said bottles, devices for filling said bottles after they have been washed, devices for corking said bottles after they have been filled, devices for wiring said bottles after they have been corked, means for causing the said devices to travel for a limited distance in engagement with the bottles, means for operating said devices while they are traveling in engagement with the bottles, means for withdrawing said devices in a direction opposite to the movement of the carrier, devices for applying labels to said bottles after they have been wired, and means for operating the said labeling devices, substantially as described.

20. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for washing the bottles, devices for filling said bottles after they have been washed, devices for corking the bottles after they have been filled, devices for wiring the bottles after they have been corked, means for causing said devices to travel for a limited distance in engagement with the bottles, means for operating said devices while they are traveling in engagement with the bottles, devices for applying labels to the bottles after they have been wired, devices for capping the tops of the bottles after they have been labeled, and means for operating the said labeling and capping devices, substantially as described.

21. The combination with a carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, devices for washing the bottles, devices for filling said bottles after they have been washed, devices for corking the bottles after they have been filled, devices for wiring the bottles after they have been corked, means for causing said devices to travel for a limited distance in engagement with the bottles, means for operating said devices while they are traveling in engagement with the bottles, means for withdrawing said devices in a direction opposite to the movement of the carrier, devices for applying labels to the bottles after they have been wired, devices for capping the tops of the bottles after they have been labeled, and means for operating the said labeling and capping devices, substantially as specified.

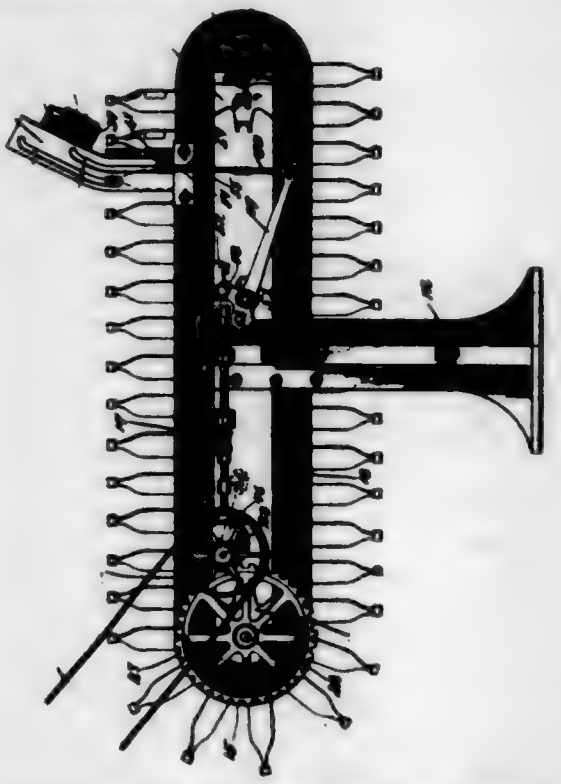
707,738. MACHINE FOR APPLYING LABELS TO BOTTLES.

CLIFTON J. WARREN, Chicago, Ill. Filed Dec. 7, 1901. Serial No. 85,000. (No model.)

Claim.—1. The combination with a carrier adapted to receive and hold a bottle, of means for moving said carrier, a label-supporting device secured over the carrier and adapted to contain a pile of labels, a movable paste-reservoir carrying an adhesive substance and adapted to be moved up and against one of said pile of labels for temporarily attaching it thereto, and means for withdrawing said reservoir carrying the label and causing said reservoir to present said attached label in the path of the bottle while said bottle is being moved.

2. The combination with a carrier adapted to receive and hold a bottle, of means for moving said carrier, a movable paste-holder carrying an adhesive substance and formed with two branches or legs so as to permit a bottle to pass between the same, a label-supporting device secured over the carrier and adapted to contain a pile of labels, means for moving said paste-holder against one of said pile of labels for temporarily attaching it thereto, and means for withdrawing said paste-holder so that its legs or branches will be at opposite sides of the moving bottle and the label carried thereby be directly in the path of the moving bottle so that each bottle forces it from the paste-holder as said bottle moves between the branches or legs thereof, substantially as specified.

3. The combination with a carrier adapted to receive and hold a bottle, of means for moving said carrier, a movable paste-holder carrying an adhesive substance and formed with two branches or legs so as to permit a bottle to pass between the same, a label-supporting device secured over the carrier and adapted to contain a pile of labels, means for moving said paste-holder against one of said pile of labels, for temporarily attaching it thereto, means for withdrawing said paste-holder so that its legs or branches will be at opposite sides of the moving bottle and the label carried thereby be directly in the path of the moving bottle so that each bottle forces it from the paste-holder as said bottle moves between the branches or legs thereof, and means for pressing said label firmly into position on said bottle, substantially as specified.



4. The combination with a carrier adapted to receive and hold a bottle, of means for moving said carrier, a movable paste-holder carrying an adhesive substance and formed with two branches or legs so as to permit a bottle to pass between the same, a label-supporting device secured over the carrier and adapted to contain a pile of labels, means for moving said paste-holder against one of said pile of labels, for temporarily attaching it thereto, means for withdrawing said paste-holder so that its legs or branches will be at opposite sides of the moving bottle and the label carried thereby be directly in the path of the moving bottle so that each bottle forces it from the paste-holder as said bottle moves between the branches or legs thereof, and a brush for smoothing said label onto said bottle as it is carried forward, substantially as specified.

5. The combination with a carrier adapted to receive and hold a bottle, of means for moving said carrier, a movable paste-holder carrying an adhesive substance and formed with two branches or legs so as to permit a bottle to pass between the same, a label-supporting device secured over the carrier and adapted to contain a pile of labels, means for moving said paste-holder against one of said pile of labels, for temporarily attaching it thereto, means for withdrawing said paste-holder so that its legs or branches will be at opposite sides of the moving bottle and the label carried thereby be directly in the path of the moving bottle so that each bottle forces it from the paste-holder as said bottle moves between the branches or legs thereof, and pivoted vertically-arranged rollers adapted to press on the label and smooth it into position against the moving bottle, substantially as specified.

6. The combination with a carrier adapted to receive and hold a bottle, means for moving said carrier, two oppositely-located supports provided with slots, means for holding a supply of labels near the upper ends of said supports, and a paste-holder having legs or extensions through which a bottle is adapted to pass and secured between the supports by pins projecting into said slots, of a rod slotted at its upper end, into which one of the guiding-pins of the paste-holder is adapted to enter, means for moving said rod to carry the paste-holder up and down between said supports, means for causing a label to adhere to said paste-holder and be there held, and means for causing the actuating-rod connected with the paste-holder to continue to move downward without being disengaged from the paste-holder after said paste-holder has reached its lowermost position, substantially as specified.

7. The combination with a movable carrier adapted to receive and hold a bottle, and means for moving the carrier, of a support adapted to contain a supply of labels, a paste-holder provided with legs adapted to embrace a bottle and provided on its face with means for the escape of paste from its interior, whereby upon being pressed against a label such label will be caused to adhere thereto, and means for reciprocating said

paste-holder to bring said label in the path of the bottle, substantially as specified.

8. In a labeling-machine, the combination with an endless carrier, and means for moving the same, of devices attached to said carrier for securing thereto a series of bottles with their neck ends projected, a pair of standards inclined at their upper ends in the direction of travel of the carrier, means for holding a supply of labels near the upper ends of said standards, a reciprocating bifurcated paste-holder located between said standards, means for reciprocating said paste-holder and directing it against the supply of labels at the inclined upper ends of the standards and causing a label to be attached thereto and thereafter presented across the path of travel of the bottles, and means for temporarily stopping said paste-holder while a bottle passes therethrough, substantially as specified.

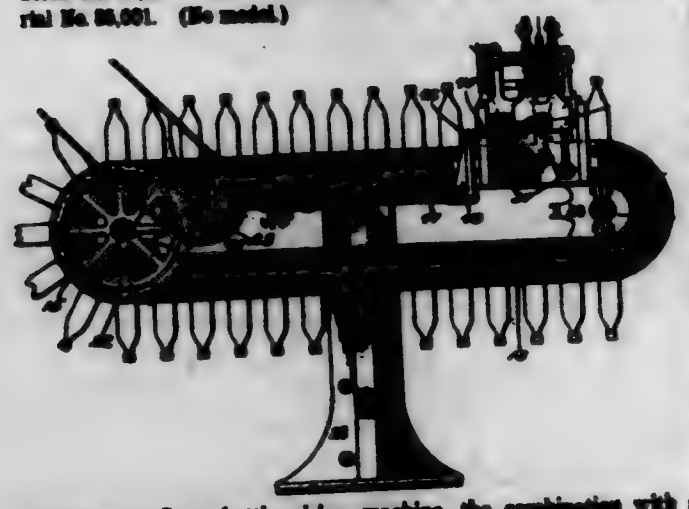
9. In a labeling-machine, the combination with an endless carrier, and means for moving the same, of devices attached to said carrier for securing thereto a series of bottles with their neck ends projected, a pair of standards, means for holding a supply of labels near the upper ends of said standards, a paste-applying device having legs or extensions through which a bottle is adapted to pass, said paste-applying device being movable between said standards, a rod connected with said paste-applying device, means for moving said rod to move the paste-applying device up and down between said standards, means for causing a label to adhere to said paste-applying device, and means for causing said rod to continue to move downward without being disengaged from the paste applying device after said paste-applying device has reached its lowermost position, substantially as specified.

10. In a labeling-machine, the combination with a carrier for the objects to be labeled and a support therefor, of a pair of standards mounted upon the support, a label-holding device carried by the standards, a reciprocating paste-holder operating between said standards and adapted to engage and feed the labels from the label-holding device to the path of the object to be labeled, means for operating said paste-holder, and means carried by the operating means for the paste-holder for operating the label-holding device to present labels to the paste-holder to be engaged thereby.

11. In a labeling-machine, the combination with a carrier for the objects to be labeled and a support therefor, of a pair of standards mounted upon the support, a label-holding device carried by the standards, a reciprocating paste-holder operating between said standards and adapted to engage and feed the labels from the label-holding device to the path of the object to be labeled, means for operating said paste-holder, means carried by the operating means for the paste-holder for operating the label-holding device to present labels to the paste-holder to be engaged thereby, a pair of vertical rollers mounted at the front of said standards, and a pair of brushes mounted at the front of the said standards above said rollers.

12. In a labeling-machine, the combination with a carrier for the objects to be labeled and a support therefor, of a pair of standards mounted upon the said support and each provided with guide-slots, a label-holding device carried by the standards, a reciprocating paste-holder operated between said standards and adapted to engage and feed the labels from the label-holding device to the path of the object to be labeled, guide-pins carried by the paste-holder and operating in the slots of the standards, and means for suitably operating said paste-holder and label-holding device.

707,789. MACHINE FOR WIRING CORKS IN BOTTLES. CLIFTON J. WARREN, Chicago, Ill. Original application filed May 16, 1901, Serial No. 60,594. Divided and this application filed Dec. 7, 1901. Serial No. 85,001. (No model.)



Claim.—1. In a bottle-wiring machine, the combination with a movable carrier adapted to receive and hold a series of bottles thereon with their neck ends projected, of means for moving said carrier, and means for successively wiring said series of bottles while they are moving, substantially as specified.

2. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, wire-directing devices located over the carrier, a wire leading therefrom, devices for grasping said wire and securing it over the end of the bottle while said bottle is moving with its carrier, means for moving said wiring devices for a limited distance parallel with and over said carrier during the operation of securing the wire to the bottle, and means for severing the wire, substantially as specified.

3. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, wire-directing devices located over the carrier, a wire leading therefrom, devices for grasping said wire and securing it over the end of the bottle while said bottle is moving with its carrier, means for moving said wiring devices down adjacent to one side of the neck of the bottle and at the same time moving them for a limited distance parallel with and over said carrier during the operation of securing the wire to the bottle, and means for severing the wire, substantially as specified.

4. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, wire-directing devices located over the carrier, a wire leading therefrom, devices for grasping said wire and securing it over the end of the bottle while said bottle is moving with its carrier, means for moving said wiring devices down adjacent to one side of the neck of the bottle and at the same time moving them for a limited distance parallel with and over said carrier during the operation of securing the wire to the bottle, means for severing the wire, and means for raising said wire-securing devices after the wire has been severed and withdrawing them for a limited distance in a direction opposite to the movement of the said carrier, substantially as specified.

5. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, wire-directing devices located over the carrier, wires leading therefrom, a fixed screw suitably supported above and parallel with the carrier, wire grasping and twisting devices carried by said screw, means for reciprocating said wire grasping and twisting devices on said screw, means for forcing said devices down and over the wires carried by said wire-directing devices and twisting them against the neck of the moving bottle, means for severing said wires when twisted, and means for raising and retracting said devices, substantially as specified.

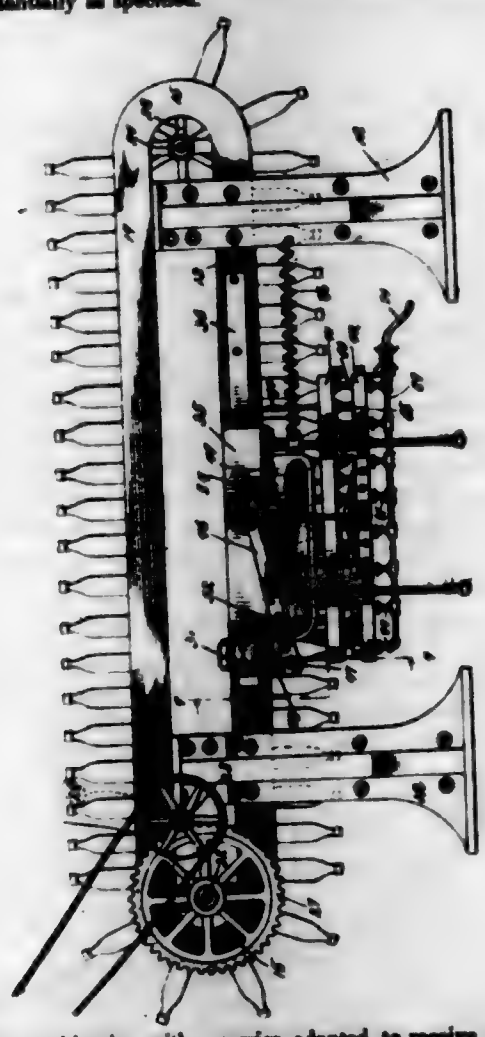
6. The combination with a frame, a carrier supported thereby and adapted to receive and hold a bottle with its neck end projected, wire-directing devices located over the carrier, and wires leading therefrom, of a fixed screw-threaded bar arranged parallel with the carrier, a gear having an extended hub mounted on said screw-threaded bar, arms mounted on said hub on opposite sides of said gear and adapted to be turned on said hub, means for reciprocating said hub on its screw-threaded bar whereby said hub and its gear will be retained, means for turning said arms for a limited distance on said hub as said hub moves lengthwise of the screw-threaded bar, a gear carried between said arms and meshing with said first-named gear, a pair of levers carried by each of said arms, cams acting upon the upper ends of said levers, a divided gear supported in the lower ends of the two pairs of levers and adapted to be opened and closed, and when closed adapted to engage the wires from the wire-directing devices and twist said wires at one side of the head of a bottle, and means for severing said twisted wires, substantially as specified.

7. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, means for moving said carrier, a frame supporting said carrier, wire-directing devices located over the carrier, and wires leading therefrom, of a slide supported by said frame, means for reciprocating said slide, a screw-threaded bar rigidly supported by said frame and parallel with the line of travel of the carrier, a gear having an extended hub, said hub being screw-threaded to fit and move upon said screw-threaded bar, a pair of cam-plates carried by arms supported from said slide, a pair of arms each having at its inner end a friction-band secured around said extended hub at each side of said gear and carrying between them at their outer ends another gear and also having pivoted to them at their outer ends two pairs of bent levers, the upper ends of which are adapted to engage the said cams, a divided gear supported between the lower ends of said two pairs of levers, the two parts of said divided gear being adapted to be brought together on the downward movement of their carrying-arms and rotated by the rotation of the other gears so as to grasp and twist at one side of a moving bottle the wires from the wire-directing devices, and means for severing said twisted wires, substantially as specified.

707,740. BOTTLE-WASHING MACHINE. CLIFTON J. WARREN, Chicago, Ill. Original application filed May 16, 1901, Serial No. 60,594. Divided and this application filed Dec. 7, 1901. Serial No. 85,004. (No model.)

Claim.—1. The combination with a carrier, and a clamping device

attached thereto and adapted to hold a bottle, of means for moving said carrier, bottle-cleansing devices, means for carrying the bottle-cleansing devices, means for moving said bottle-cleansing devices toward the bottle to be cleaned so that the cleansing devices are brought into operative position, means for moving the bottle-cleansing devices for a limited distance parallel with the moving carrier, means for operating said cleansing devices, and means for withdrawing the cleansing devices from operative position, substantially as specified.



2. The combination with a carrier adapted to receive and hold a bottle with its neck end projected beyond the carrier, of means for moving said carrier, reciprocating mechanism carrying a water-conducting tube adapted to enter the bottle, means for conveying water to said tube, means for moving said reciprocating mechanism toward the bottle to cause the water-conducting tube to enter therein, means for moving said mechanism for a limited distance parallel with the moving carrier, and means for drawing the said mechanism away from the bottle and withdrawing the said tube from the interior of the bottle, substantially as specified.

3. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a plate carrying a water-conducting tube adapted to enter the bottle, means for supplying water to and through said tube, means for moving said plate toward the bottle to cause the water-conducting tube to enter therein, means for rotating the water-conducting tube while in the bottle, means for moving the said plate for a limited distance parallel with the moving bottle-carrier, and means for drawing the plate away from the bottle and withdrawing the said tube from the interior thereof, substantially as specified.

4. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a plate carrying a water-conducting tube adapted to enter the bottle, means for moving said plate toward the bottle to cause the water-conducting tube to enter therein, a rotatable gear carried by said plate and adapted when turned to rotate said water-conducting tube when in the bottle, means for rotating said gear, means for moving the plate for a limited distance parallel with the moving carrier, and means for drawing the plate away from the bottle and withdrawing the said tube from the interior thereof, substantially as specified.

5. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a plate carrying a water-conducting tube adapted to enter the bottle, means for moving said plate toward the bottle to cause the water-conducting tube to enter therein, a gear-wheel secured to said water-conducting tube and carried by said plate, a second gear-wheel also carried by said plate and meshing with the first-named gear-wheel, a screw-threaded rod carried by said second-named gear-wheel, a fixed threaded sleeve through which said screw-threaded rod passes, whereby as said rod is moved through said sleeve motion will be imparted to the said gear-wheels, means for moving the plate for a limited distance parallel with the moving bottle-carrier, and means for drawing said plate away from the bottle and withdrawing the said water-conducting tube from the interior thereof, substantially as specified.

6. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a movable frame carrying a water-conducting tube adapted to enter a bottle, a guide carried by said frame through which said water-conducting tube is adapted to pass and be supported, means for moving said frame toward the bottle to cause the water-conducting tube to enter therein, means for moving said frame for a limited distance parallel with the moving bottle-carrier, and means for drawing the frame away from the bottle and withdrawing the said water-conducting tube from the interior thereof, substantially as specified.

7. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a frame carrying a flexible water-conducting tube adapted to enter a bottle, a guiding and supporting rod within said flexible tube, means for moving said carrier toward the bottle to cause the water-conducting tube to enter therein, means for moving the frame for a limited distance parallel with the moving bottle-carrier, and means for drawing the frame away from the bottle and withdrawing the said flexible tube and its interior guiding and supporting rod from the interior of the bottle, substantially as specified.

8. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, means for moving said carrier, and a frame consisting of an upper and a lower part, both adapted to move in the direction of travel of the carrier, and the lower part having an independent vertical movement, of a water-conducting tube adapted to enter a bottle, said tube being carried by the lower part of the frame, a guide attached to the upper part of the frame, through which guide the water-conducting tube is adapted to pass, means for moving said frame with the line of travel of the carrier, means for moving the lower part of said frame at the same time toward the bottle to cause the water-conducting tube to enter therein, and means for drawing the frame away from the bottle and withdrawing the said tube from the interior thereof, substantially as specified.

9. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, means for moving said carrier, and a frame consisting of an upper and a lower part, both adapted to move in the direction of travel of the carrier, and the lower part having an independent vertical movement, of a water-conducting tube adapted to enter a bottle, said tube being carried by the lower part of the frame and projecting through the upper part of the frame, means for moving said frame in the direction of the line of travel of the carrier, means for moving the lower part of said frame at the same time toward the bottle to cause the water-conducting tube to enter therein, and means for drawing the frame away from the bottle and withdrawing the said tube from the interior thereof, substantially as specified.

10. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, means for moving said carrier, and a frame consisting of an upper and a lower part, both adapted to move in the direction of travel of the carrier, and the lower part having an independent vertical movement, of a water-conducting tube adapted to enter a bottle, said tube being carried by the lower part of the frame, a sleeve surrounding said water-conducting tube and located in an opening in the upper part of the frame and provided on its upper end with a head adapted to fit over the head of a bottle, means for moving said frame within the line of travel of the carrier, means for moving the lower part of said frame vertically, a device for forcing up the said sleeve to cause the head thereon to come over the head of the bottle on said carrier, means for directing the water-conducting tube into the bottle as the lower part of the frame rises, and means for drawing the frame away from the bottle and withdrawing the said tube from the interior thereof, substantially as specified.

11. The combination with a carrier adapted to receive and hold a bottle, of means for moving said carrier, a frame, bottle-cleansing devices carried by said frame, means for moving said frame toward the bottle to be cleansed so that the cleansing devices are brought into operative position, means carried by the carrier for moving the bottle-cleansing devices with the movement of the carrier for a limited distance, means for moving the bottle-cleansing devices away from the bottle, and means for releasing the engagement between the carrier and the frame that carries the bottle-cleansing devices, substantially as specified.

12. The combination with a carrier adapted to receive and hold a bottle, means for moving said carrier, a frame, and bottle-cleansing devices carried by said frame, of means for moving said frame toward the

bottle to be cleaned so that the cleaning devices are brought into operative position, means carried by the carrier for moving the bottle-cleaning devices with the movement of the carrier for a limited distance, means for moving the bottle-cleaning devices away from the bottle, means for effecting the engagement between the carrier and the frame that carries the bottle-cleaning devices, and means for returning said frame after its disengagement from the carrier, said frame on its return moving in a direction opposite to that of the travel of the carrier, substantially as specified.

13. The combination with a carrier adapted to receive and hold a bottle, means for moving said carrier, a slide adapted to move for a short distance parallel with said carrier, bottle-cleaning devices, and a frame adapted to carry said bottle-cleaning devices, of means for causing said frame to travel toward the bottle on the carrier to bring the bottle-cleaning devices into operative position, an engaging device on the movable carrier, a pivoted dog carried by the slide and adapted to be engaged by the engaging device of the carrier, whereby said slide and attached frame can move with the carrier, a device for lifting said pivoted dog out of engagement with the carrier, and means for forcing the said frame away to carry the bottle-cleaning devices out of operative position, substantially as specified.

14. The combination with a carrier adapted to receive and hold a bottle, of a slide adapted to be engaged by the carrier and move therewith, a frame secured to said slide, a lever pivotally connected at one end with the slide and at the other end with the said frame, a fixed plate having a groove in the face thereof, the upper portion of said groove being diagonal and the lower portion horizontal, a roller carried by said lever and adapted to travel in said groove, and means for disengaging the slide from the moving carrier, substantially as specified.

15. The combination with a carrier adapted to receive and hold a bottle, of a slide adapted to be engaged by the carrier and move therewith, a frame secured to said slide, a lever pivotally connected at one end with the slide and at the other end with the said frame, a fixed plate having a groove in the face thereof, the upper portion of said groove being diagonal and the lower portion horizontal, a roller adapted to travel in said groove, said roller being loosely mounted on a pin projecting from the side of said roller and being held in position by a coiled spring around said pin between said roller and lever, and a device for disengaging the slide from the moving carrier, substantially as specified.

16. The combination with a carrier adapted to receive and hold a bottle, of a slide adapted to be engaged by the carrier and move therewith, a frame secured to said slide, a lever pivotally connected at one end with the slide and at the other end with the said frame, a fixed plate having a groove in the face thereof, the upper portion of said groove being diagonal and the lower portion horizontal, a roller adapted to travel in said groove, said roller being rotatably secured to said lever, and a device for disengaging the slide from the moving carrier, substantially as specified.

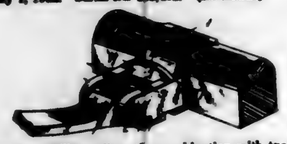
17. The combination with a carrier adapted to receive and hold a bottle, of means for moving said carrier, devices for cleaning the outside of the bottle, a frame for carrying said cleaning devices, means for moving said frame toward the bottle to cause the bottle-cleaning devices to be brought into operative position opposite the bottle, means for moving said frame for a limited distance parallel with the moving bottle-carrier, and means for drawing the said frame away from the bottle and withdrawing from operative position the said bottle-cleaning devices, substantially as specified.

18. The combination with a carrier adapted to receive and hold a bottle, of means for moving said carrier, devices for throwing water against the outer surface of the bottle, a frame for carrying said water-throwing devices, means for moving said frame toward the bottle to cause the water-throwing devices to be brought opposite said bottle, means for moving the frame for a limited distance parallel with the bottle-carrier, and means for drawing the frame away from the bottle and thereby withdrawing the said water-throwing devices out of operative position, substantially as specified.

19. The combination with a carrier adapted to receive and hold a bottle, of means for moving said carrier, a cleaning-brush adapted to contact with the outside of the bottle, a frame for carrying said brush, means for rubbing said brush while in contact with the bottle, means for moving the frame for a limited distance parallel with the moving bottle-carrier, and means for drawing the frame away from the bottle and withdrawing the said brush from contact therewith, substantially as specified.

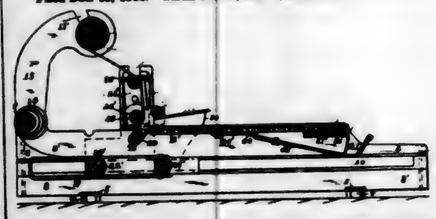
20. The combination with a carrier adapted to receive and hold a bottle, of means for moving said carrier, a device for discharging water against the outside of the bottle, a brush adapted to be brought in contact with the outside of the bottle, a frame for carrying both said water-discharging device and brush, means for moving said frame toward the bottle in order to bring said water-discharging device and brush into operative position with reference to the bottle, means for rotating said water-discharging device and brush, means for moving the frame for a limited distance parallel with the moving bottle-carrier, and means for drawing the frame away from the bottle and withdrawing the said water-discharging device and brush from operative position with reference to the bottle, substantially as specified.

707,741. THILL-COUPLING. THOMAS F. WARE, Cuba, Cal. Filed May 1, 1902. Serial No. 105,472. (No model.)



Claim.—In a thill-coupling, the combination with the ears having upon their inner faces L-shaped slots, of a thill-iron, a pivotal bolt for the thill-iron located in the horizontal portion of said L-shaped slots, an angular spring provided with studs journaled in bearings formed in the lower edges of the ears, a hard-rubber washer having a dovetail connection with the lower end of said spring, a bolt having a flattened portion at its upper end terminating in laterally-projecting lugs which are adapted to engage the upper edges of the ears, said flattened portion being provided with a transverse dovetail recess, a rubber packing seated in said recess, the lower end of said bolt projecting through the lower end of the spring and the hard-rubber washer, and a nut screwed upon the lower end of said bolt, substantially as set forth.

707,742. CIGAR-BUNCHING MACHINE. WILLIAM WEIBEZAHN and EDWARD S. DENNIS, Pittsburg, Pa., assignors to the Pittsburgh Cigar Machine Company, Pittsburg, Pa., a Corporation of Pennsylvania. Filed Dec. 13, 1900. Serial No. 39,505. (No model.)



Claim.—1. In a cigar-bunching machine, the combination of a stationary main supporting-frame having tracks therein, a bunching-table within said frame, an apron passing over said table and adapted to form a pocket therein, a roller-carrying mechanism and a binder-table mechanism adapted to travel on said tracks, means connected to said roller-carrying mechanism for moving the same forward, connections from said roller-carrying mechanism to the binder-table mechanism, to permit the former to strike against the latter, and a leaf-spring connected to said frame and roller-carrying mechanism for permitting the latter and binder-table mechanism to move forward over the table to form a bunch in said pocket and be returned to place.

2. In a cigar-bunching machine, the combination of a stationary main supporting-frame having tracks therein, a bunching-table within said frame, an apron passing over said table and adapted to form a pocket therein, a roller-carrying mechanism and a binder-table mechanism provided with slides thereon adapted to travel on said tracks, handles connected to said roller-carrying mechanism for moving the same forward, slotted arms on said binder-table mechanism adapted to engage with said roller-carrying mechanism to permit the latter to strike against the former, move forward and return to place with it, and a leaf-spring connected to said frame and roller-carrying mechanism for permitting the latter and the binder-table mechanism to move forward over the table to form a bunch in said pocket and be returned to place.

3. In a cigar-bunching machine, the combination of a frame, a bunching-table on said frame, a rigid portion extending down in front of said table having a lip at its upper end secured to the bottom of said table, an extension on the lower end of said rigid portion secured to the bottom of said table, and an adjustable spring portion extending up in front of said rigid portion and secured to the extension to form a bunch-catcher.

4. In a cigar-bunching machine, the combination of a frame, a bunching-table on said frame, a rigid portion extending down in front of said table having a lip at its upper end secured to the bottom of said table, an extension on the lower end of said rigid portion secured to the bottom of said table, a spring portion extending up in front of said rigid portion to form a bunch-catcher therewith, and a spring extension on said spring portion, and a bolt engaging with a slot in the extension of the rigid portion and spring portion to adjust the latter.

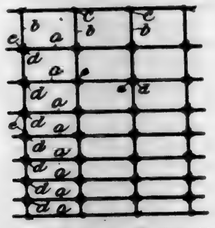
5. In a cigar-bunching machine, the combination of a frame, a bunching-table within said frame, an apron or cloth mounted in said frame and adapted to form a pocket before passing over the bunching-table, a binder-table on said frame, a bunching-roll journaled on said frame, an apron-guiding roll mounted above said bunching-roll, and a binder-stretching roll mounted in front of and on substantially the same horizontal level with the bunching-roll, said stretching-roll being adapted to reciprocate horizontally with the binding-roll.

6. In a cigar-bunching machine, the combination of a stationary main supporting-frame having recesses therein, bearing-blocks on said frame provided with slots in their lower ends, and a bunching-roll adapted to be held in said slots and be removed therefrom into the recesses in the frame.

7. In a cigar-bunching machine, the combination of a frame, and a bunching-table mounted on said frame, said table having a series of grooves in its upper face at the rear end thereof for compacting the bunch and a smooth upper face at the front end thereof for smoothing the bunch after being compacted.

8. In a cigar-bunching machine, the combination of a frame, a bunching-table within said frame, a reciprocating bunching-roll mounted on said frame having tapered and enlarged cylindrical portions thereon, and an apron or cloth mounted on said frame and adapted to engage with the enlarged portions before forming a pocket and passing on to the bunching-table.

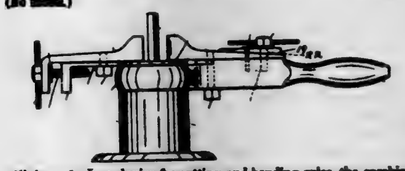
707,743. WOVEN-WIRE FENCING. ARTHUR W. WELLMAN, Madison, Wis. Filed Mar. 5, 1901. Serial No. 49,894. (No model.)



Claim.—1. In a fence-tie, the combination with strand and stay wires, of a tie-wire continuously coiled in one direction and having its opposite ends formed in two coils at an angle to each other and respectively parallel to and engaging the adjacent strand and stay wires, and a connecting portion between the coils extending across the angle from one coil to the other and at one side of the point of intersection between the strand and stay wires; substantially as specified.

2. In a fence-tie, the combination with strand and stay wires, of a tie-wire having its opposite end formed in two coils at an angle to each other and respectively parallel to and engaging the adjacent strand and stay wires, a connecting portion between the coils extending across the angle from one coil to the other and at one side of the point of intersection between the strand and stay wires, and a duplicate tie-wire disposed at the opposite side of the point of intersection between the strand and stay wires to the first-mentioned tie-wire; substantially as specified.

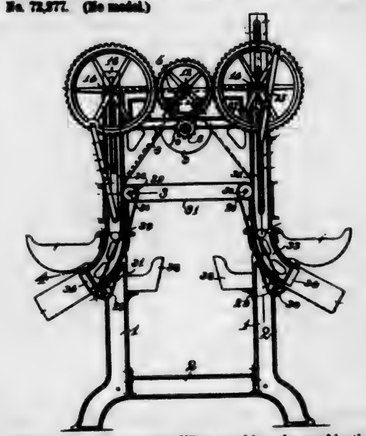
707,744. MACHINE FOR CUTTING AND BENDING RULES. JOEL WELTY, Fort Wayne, Ind. Filed May 31, 1901. Serial No. 62,602. (No model.)



Claim.—1. In a device for cutting and bending rules, the combination with a standard provided at its upper end with a neck, of an operating-handle having at one of its ends a collar mounted upon said neck, a plate secured to said standard and overlapping the collar of said handle for securing the collar upon said neck, said plate being provided with an outwardly-extending arm having its outer end bent downwardly, a removable die fitted in said standard, a gripper adjustably mounted upon said plate, an adjusting-screw mounted in the outer end of said gripper and engaging the downwardly-bent end of said plate, and a former adjustably mounted upon said operating-handle, the faces of said gripper and former being arranged in parallel relation and maintaining such relation during the adjustments thereof.

2. In a device for cutting and bending rules, the combination with a standard provided at its upper end with a neck, of an operating-handle having at one of its ends a collar mounted upon said neck, a plate secured to said standard and overlapping the collar of said handle for securing the collar upon said neck, said plate being provided with an outwardly-extending arm having its outer end bent downwardly, a removable die fitted in said standard, a gripper adjustably mounted upon said plate, an adjusting-screw mounted in the outer end of said gripper and engaging the downwardly-bent end of said plate, a former adjustably mounted upon said operating-handle and provided with a longitudinal slot, a plate mounted on said former and provided with a lug engaging the operating-handle, and a screw passing through said plate and the former and engaging the operating-handle for securing the plate and former on the handle.

707,745. MATTRESS-FILLING MACHINE. KARL WIESEL, St. Paul, Minn., assignor to the Curled Fibre Manufacturing Company, St. Paul, Minn., a Corporation of Delaware. Filed Aug. 16, 1901. Serial No. 72,377. (No model.)



Claim.—1. In a mattress-filling machine, the combination with a forming-chute, means for adjusting the width thereof, a reciprocating feeding and packing plunger arranged to operate in said chute, means for continuously reciprocating said plunger, and means whereby the width of said plunger is varied to correspond with the adjusted width of the forming-chute.

2. In a mattress-filling machine, the combination with a forming-chute adjustable in width, of a reciprocatory feeding and packing plunger also and correspondingly adjustable in width, means for continuously reciprocating said plunger, and means for simultaneously effecting the adjustments in width of said chute and plunger.

3. In a mattress-filling machine, the combination with a forming-chute, and means for adjusting the width thereof, of a plunger movable into and out of said forming-chute and adjustable in width, means for continuously reciprocating said plunger, and connection between said plunger and said adjusting means for adjusting the width of said forming-chute, whereby said plunger will be adjusted in width simultaneously with said forming-chute.

4. In a mattress-filling machine, the combination with a forming-chute having laterally-movable side walls whereby the same is made adjustable in width, of a reciprocating plunger movable into and out of said chute, means for presenting filling material to the action of said plunger, whereby said filling material is compressed into said chute in successive increments, means for adjusting the width of said plunger, connection between said plunger and said side walls of said forming-chute whereby the plunger will be adjusted in width simultaneously with said forming-chute, and means for continuously reciprocating said plunger.

5. In a mattress-filling machine, the combination with a forming-chute and a reciprocating plunger movable therein, said plunger being adjustable in width, means for continuously reciprocating said plunger, and means for constantly presenting the filling material to the action of said plunger, of devices common to both said forming-chute and said plunger for simultaneously adjusting the width of each.

6. In a mattress-filling machine, the combination with a forming-

chute, means for continuously feeding a filling thereto in successive increments, compressing said filling therein and forcing same therethrough, of devices for adjusting the width of said forming-chute and said feeding and compressing means, and means controlling the degree of compactness or compression imparted to said filling.

7. In a mattress-filling machine, the combination of a feed chute or passage adapted to receive a mattress or other cover over the discharge end thereof, and means for feeding a filling material through said chute or passage, the sides of said feed chute or passage having openings therethrough to permit the application of a lining to the surface of said material whereby the lining is engaged by the surface of the filling material and is drawn therewith into and through the chute or passage, as and for the purpose set forth.

8. In a mattress-filling machine, a feed chute or passage adapted to receive a mattress or other cover over the discharge end thereof, means for continuously compressing a filling-material into and feeding the same through said chute or passage and into said cover, said feed chute or passage having openings therethrough whereby a lining may be introduced into said chute or passage, applied to the surface of said filling material and engaged by said fed along with said material into said cover, as and for the purpose set forth.

9. In a mattress-filling machine, a chute or passage, a reciprocating plunger operating therein for feeding a filling material therethrough, a mattress or other cover adapted to receive said filling material from the discharge end of said chute or passage, said chute or passage provided with slots or openings, to receive linings therethrough whereby said lining is engaged by said fed along with said material into said cover, as and for the purpose set forth.

10. In a mattress-filling machine, a chute or passage constructed to receive a mattress-cover over the delivery end thereof, means for delivering a filling material into said chute or passage, means for continuously feeding said material through said chute or passage and into said cover, said chute or passage provided with slots adjacent the delivery end thereof through which a lining material for the surface of said material may be introduced into said chute or passage, said lining material being adapted to be engaged by said filling material and drawn into and through said chute or passage and into said cover, as and for the purpose set forth.

11. In a mattress-filling machine, the combination with a forming-chute, a plunger, means for reciprocating the same into and out of one end thereof and adapted to force continuously filling in successive increments into and through said chute and compress same therein, of means for introducing a lining into said chute between the ends of the latter to be engaged by the surface of said forced through said chute with said filling.

12. In a mattress-filling machine, the combination with a reciprocating plunger, of a forming-chute in which said plunger moves and through which it is adapted to force a filling, a telescopically-adjustable mouth on said forming-chute adapted to have a mattress-cover drawn over same, and lateral slots in said forming-chute for introducing cotton to cover said filling and be drawn into the mattress-cover therewith.

13. In a mattress-filling machine, the combination with a reciprocating plunger comprising a plurality of parallel plates mounted side by side and relatively movable, whereby said plunger is adjustable in width, of a forming-chute in which said plunger moves and through which it is adapted to force a filling, means for adjusting the inner width of said forming-chute, a telescopically-adjustable mouth on said forming-chute adapted to have a mattress-cover drawn over same, said forming-chute being provided with lateral slots for the introduction of cotton or other suitable covering for said filling, said filling being adapted to engage said covering to draw same through said forming-chute.

14. In a mattress-filling machine, the combination with a reciprocating plunger comprising a plurality of plates laterally movable and connected together by lazy-tong levers, whereby, by adjusting the distance between any two of said plates, the entire series will be similarly adjusted, of a forming-chute in which said plunger moves and through which it is adapted to force a filling, means for adjusting the inner width of said forming-chute, and a telescopically-adjustable mouth on said forming-chute adapted to have a mattress-cover drawn over same, said forming-chute being provided with lateral slots for the introduction of cotton or other suitable covering for said filling, said filling being adapted to engage said covering to draw same through said forming-chute.

15. In a mattress-filling machine, the combination with a forming-chute, and plates laterally movable therein for adjusting the inner width thereof, of a plunger reciprocally movable in said forming-chute and adjustable in width to correspond with the width of said forming-chute, said plunger being connected with said plates and laterally rigid therewith, whereby said forming-chute and said plunger are simultaneously adjusted, and a laterally telescopically adjustable mouth on said forming-chute adapted to have a mattress-cover drawn over same, said forming-chute being provided with lateral slots for the introduction of cotton or other suitable covering for said filling, said filling being adapted to engage said covering to draw same through said forming-chute.

16. In a mattress-filling machine, the combination with a forming-chute and plates laterally movable therein for adjusting the inner width thereof, of a plunger reciprocally movable in said forming-chute comprising a plurality of parallel plates mounted side by side and which are laterally movable and connected together by lazy-tong levers, whereby by adjusting the distance between any two of said plates the entire series will be similarly adjusted, said plunger being connected with the adjustable plates in said forming-chute and laterally rigid therewith, whereby said forming-chute and said plunger are simultaneously adjusted in width, and a laterally telescopically adjustable mouth on said forming-chute adapted to have a mattress-cover drawn over same, said forming-chute being provided with lateral slots for the introduction of cotton or other suitable covering for said filling, said filling being adapted to engage said covering to draw same through said forming-chute.

17. In a mattress-filling machine, the combination with a forming-chute curved at its delivery-end portion and carrying a laterally telescopically adjustable mouth adapted to have a mattress-cover drawn over same, of laterally-movable plates fitting within said forming-chute and adapted to adjust the inner width of same, a plunger longitudinally movable in said forming-chute and laterally adjustable, said plunger being laterally rigid with said plates and adjustable by moving said plates.

18. In a mattress-filling machine, the combination with a forming-chute curved at its delivery-end portion and carrying a laterally telescopically adjustable mouth adapted to have a mattress-cover drawn over same, of laterally-movable plates fitting within said forming-chute and adapted to adjust the inner width of same, a plunger longitudinally movable in and adapted to force a filling through said forming-chute, comprising a series of parallel slats mounted side by side and connected with a set of lazy-tong levers whereby by adjusting the distance between any two of said slats the entire series will be similarly adjusted, the two outer slats of said series being laterally rigidly connected to said laterally-movable plates in said forming-chute, whereby when said plates are adjusted said plunger is simultaneously adjusted in width to correspond with the width of said forming-chute.

19. In a mattress-filling machine, the combination with a forming-chute curved at its delivery-end portion and carrying a laterally telescopically adjustable mouth adapted to have a mattress-cover drawn over same, of laterally-movable plates fitting within said forming-chute and adapted to adjust the inner width of same, a plunger longitudinally movable in and adapted to force a filling through said forming-chute, comprising a series of parallel slats mounted side by side and connected with a set of lazy-tong levers whereby by adjusting the distance between any two of said slats the entire series will be similarly adjusted, the two outer slats of said series being laterally rigidly connected to said laterally-movable plates in said forming-chute, whereby when said plates are adjusted said plunger is simultaneously adjusted in width to correspond with the width of said forming-chute, said forming-chute being provided with lateral slots for the introduction of cotton or other suitable covering for said filling, said filling being adapted to engage said covering to draw same through said forming-chute.

20. In a mattress-filling machine, the combination with a reciprocating plunger adjustable in width, of a laterally-adjustable forming-chute coacting with said plunger to form a mattress-filling, said plunger being adapted to continuously deliver said filling in increments into and move the same through said forming-chute, said forming-chute being provided with lateral slots for the introduction of cotton or other suitable covering for said filling, the surface of said filling being adapted to engage said covering to draw same through said forming-chute.

21. In a mattress-filling machine, the combination with a vertically-reciprocating plunger, of a forming-chute coacting with said plunger, said forming-chute being curved at its delivery end so as to deliver said mattress-filling laterally, at an angle, to that portion of said forming-chute in which said plunger operates.

22. In a mattress-filling machine, the combination with a plunger, of a forming-chute coacting with said plunger, said forming-chute being curved at its delivery end, whereby the passage of the filling is resisted and the latter compressed to a given compactness.

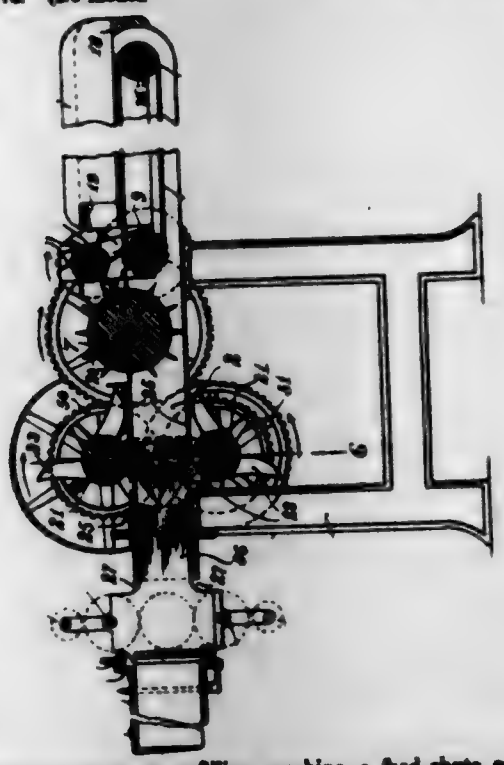
23. A mattress-filling machine, comprising a forming-chute, means for adjusting the width of said forming-chute, a reciprocating plunger movable into and out of one end of said forming-chute, and means for continuously presenting mattress-filling material in front of the mouth of said forming-chute and between the limits of motion of said plunger, means for forcing said filling into the path of said plunger, and devices at the mouth of said forming-chute adapted to be moved out of the path of the incoming filling and project behind the same to prevent said filling from leaving said mouth of said forming-chute, the delivery end of said forming-chute being adapted to receive a mattress-cover, whereby said filling will enter said mattress-cover thereover and withdraw same from said forming-chute, substantially as described.

24. A mattress-filling machine, comprising a forming-chute, means for adjusting the width of said forming-chute, a plunger movable into and out of one end of said forming-chute, means for continuously presenting filling material in front and into the path of said plunger, said forming-chute being provided with a slot adjacent the rear end of same through which a cotton fabric or top is adapted to be inserted to be engaged by the surface of said filling, the rear end of said forming-chute comprising an open-ended casing adapted to receive a mattress-cover which said filling and said cotton fabric or top are adapted to enter and which serve to withdraw said cover from said forming-chute, substantially as described.

25. In a mattress-filling machine, the combination with a forming-chute, adjustable in width and having an open-ended casing forming a delivery end adapted to receive a mattress-cover telescoped thereover, of devices for continuously presenting filling material into said forming-chute and forcing same therethrough and into said mattress-cover, said forming-chute being provided with a slot between its ends adapted to admit a layer of suitable material adapted to form a top for said filling, the latter being engaged by the surface of said filling and drawn thereby through said forming-chute and into said mattress-cover therewith, substantially as described.

26. In a mattress-filling machine, the combination with a forming-chute adjustable in width and having an open-ended casing forming a delivery end adapted to receive a mattress-cover telescoped thereover, and provided between its ends with a transverse slot adapted to admit a lining material, of a reciprocating plunger adapted to receive a separate head to correspond with each variation in the width of said forming-chute and operating into and out of the other end of said forming-chute, and means for continuously presenting filling material into the path of said plunger, whereby said filling is forced into and through said forming-chute into said mattress-cover, the surface of said filling engaging said lining material and drawing same therewith into said mattress-cover, substantially as described.

707,746. MATTRESS-FILLING MACHINE. Karl Wiesel, St. Paul, Minn., assignor to the Curled Fibre Manufacturing Company, St. Paul, Minn., a Corporation of Delaware. Filed Aug. 16, 1901. Serial No. 72,273. (No model.)



Claim.—1. In a mattress-filling machine, a feed chute or passage adapted to receive a mattress or other cover over the discharge end thereof, and having openings or slots in the wall thereof, in combination with a shaft arranged to extend transversely of said chute or passage and carrying fingers arranged to project through said slots or openings and into said chute or passage, and means for rotating said shaft whereby the filling material introduced to said chute or passage is engaged by said fingers and is continuously fed thereby through and discharged from said chute or passage into said cover, as and for the purpose set forth.

2. In a mattress-filling machine, a feed chute or passage adapted to receive a mattress or other cover over the discharge end thereof, shafts arranged on opposite sides of said chute or passage and to extend transversely thereof, fingers mounted upon said shafts and arranged to project into said chute or passage, and means for rotating said shafts in opposite directions, whereby the filling material introduced into said chute or passage is continuously fed through and discharged from said chute or passage and into said cover, as and for the purpose set forth.

3. In a mattress-filling machine, the combination with a feed chute or passage, of feed-shafts extending transversely of said chute or passage and carrying feed-fingers arranged to project into said chute or passage, means for delivering the filling material into said chute or passage, and means for rotating said feed-shafts whereby such filling material is continuously fed through said chute or passage, as and for the purpose set forth.

4. In a mattress-filling machine, the combination with a feed chute or passage having a discharge end, means for delivering a filling material into said feed chute or passage, and movable feeding-fingers arranged to project into said chute or passage and having rearwardly-curved front or feeding edges, as and for the purpose set forth.

5. In a mattress-filling machine, the combination with a feed chute or passage having a discharge end, the walls of said chute or passage being slotted, feed-shafts transversely arranged and having feed-fingers arranged to operate through said slots, the forward or feeding edges of said fingers being curved rearwardly with reference to the direction of rotation of said shafts, means for rotating said shafts, and means for delivering a filling material into said feed chute or passage, as and for the purpose set forth.

6. In a mattress-filling machine, a feed chute or passage, means for delivering the filling material into said chute or passage, means for straightening or combing said filling material, and feed-fingers arranged to project into said chute or passage and means for actuating the same to continuously and uniformly feed the material through said passage or chute, as and for the purpose set forth.

7. In a mattress-filling machine, a feed chute or passage, means for delivering the filling material thereto, feeding devices arranged to project into said chute or passage for continuously feeding the material therethrough, in combination with restraining devices arranged on the delivery side of said feeding devices for restraining the discharge of the material without arresting the action of said feeding mechanism while a filled mattress is being removed, as and for the purpose set forth.

8. In a mattress-filling machine, the combination with mechanism for continuously feeding the filling material, of restraining-fingers arranged on the delivery side of said feeding mechanism, and adapted to be projected into the path of the material for restraining the discharge thereof without arresting the action of said continuous-feeding mechanism, as and for the purpose set forth.

9. In a mattress-filling machine, a feed chute or passage, means for delivering the filling material thereto, means for continuously feeding such material through said passage or chute, and rock-shafts having arms arranged to be projected into the path of said material to restrain the discharge thereof while a filled mattress is being removed, as and for the purpose set forth.

10. In a mattress-filling machine, the combination with a feeding chute or passage, means for delivering the filling material thereto, rotating fingers arranged to project into said chute or passage to continuously feed the material therethrough, and means for adjusting the transverse width of said chute or passage, as and for the purpose set forth.

11. In a mattress-filling machine, the combination with a feed chute or passage adapted to receive a mattress or other cover over the discharge end thereof, said chute or passage being adjustable in transverse width, feed-fingers arranged to project into said chute or passage, and means for moving said fingers to continuously feed the material and discharge the same into said cover, as and for the purpose set forth.

12. In a mattress-filling machine, the combination with a feed chute or passage, means for delivering a filling material thereto, said chute or passage provided with slots in the top and bottom walls thereof, shafts journaled above and below said chute or passage through said slots, said arms or fingers cooperating to feed the filling material toward the delivery end of said chute or passage, and means for rotating said shafts, as and for the purpose set forth.

13. In a mattress-filling machine, a delivery-carrier, combing devices arranged adjacent to the point of delivery of said carrier, a feed chute or passage, fingers arranged to project into said chute or passage to continuously feed the material therethrough, whereby the filling material is continuously progressed toward the discharge end of said feed chute or passage, as and for the purpose set forth.

14. In a mattress-filling machine, a delivery-carrier, combing or straightening devices arranged adjacent to the delivery end of said carrier, a feed passage or chute adapted to receive the filling material from said straightening or combing devices, feed-fingers arranged to project into said feed chute or passage, and means for actuating these several parts, as and for the purpose set forth.

15. In a mattress-filling machine, a delivery-carrier, means arranged adjacent to the delivery end thereof for straightening and combing the filling material delivered therefrom, a feed chute or passage adapted to receive the filling material from said scraping or combing devices, movable feed-fingers arranged to operate in said chute or passage for continu-

ously feeding the filling material toward the discharge end of said chute or passage, means for rotating these several parts, and means for applying a lining to the surface of said filling material as it progresses through said chute or passage, as and for the purpose set forth.

707,747. STONE OR PLATE FOR PHOTOMECHANICAL PRINTING AND FOR OTHER PURPOSES, AND METHOD OF PREPARING SAME. GERALD F. WETHERMAN and GEORGE HOLMATHER, Redcar, England. Filed Jan. 31, 1902. Serial No. 92,073. (No model.)

Claim.—1. A process of sensitizing a stone, plate or the like by applying thereto first a dilute sensitizing compound or mixture and then an undiluted or full-strength sensitizing compound or mixture.

2. A process of sensitizing a stone plate or the like by applying thereto a preparatory coating, then a "priming" of dilute sensitizing compound or mixture, and finally an undiluted or full-strength sensitizing compound or mixture.

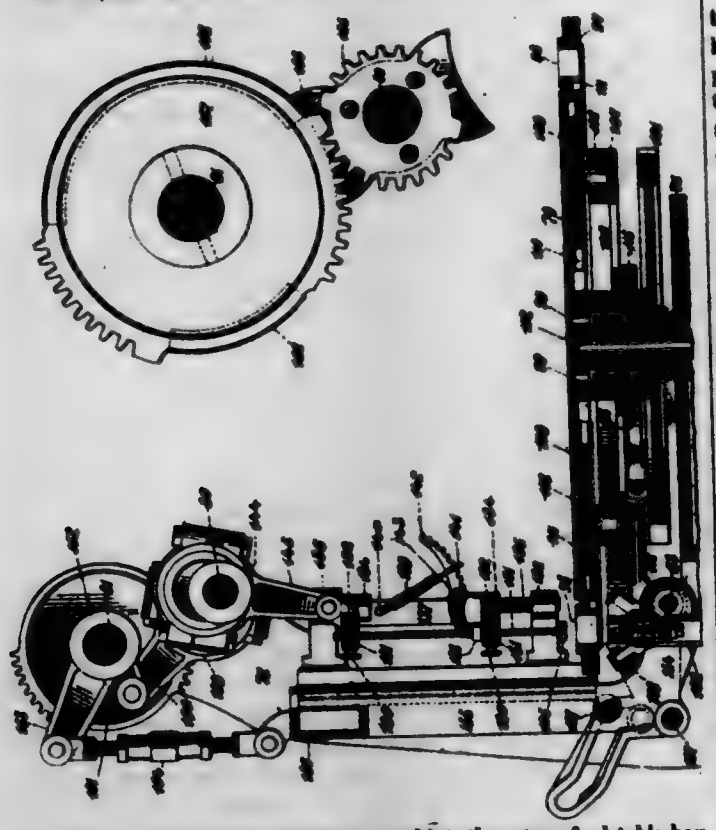
3. A process of preparing sensitized plates stones or the like by first coating the same with a solution of silicate of potash and tannin in beer, drying the same and when dry "priming" the surface, after which it is coated with full-strength sensitizer.

4. A process of preparing plates stones or the like by a solution of silicate of potash and tannin in beer, priming the same with a dilute sensitizing compound or mixture and, before the priming dries, coating them with undilute sensitizing compound or mixture.

5. A process for sensitizing plates stones or the like with a compound or composition the base of which is gelatin sensitized by chrome salts, preparing such compound or composition in full strength, a like composition or compound greatly diluted, "priming" the surface to be sensitized with the dilute compound or composition, and then coating it with the compound or composition of full strength.

6. A process of sensitizing plates stones or the like by first coating the same with a solution of silicate of potash and tannin in beer, drying this first coating, priming the surface with a dilute compound or composition the base of which is gelatin, and then coating it with a sensitive coating of full-strength compound or composition the base of which is gelatin sensitized by chrome salts.

707,748. CIGAR-BUNCHING MACHINE. JOHN R. WILLIAMS, East Orange, N. J., assignor to the John R. Williams Company, New York, N. Y., a Corporation of New York. Filed June 13, 1902. Serial No. 111,508. (No model.)



Claim.—1. In a cigar-bunching machine, the rotary feed-table having the series of pockets or molds for receiving the filler-tobacco, means for imparting an intermittent rotary motion to said table, and means for locking said table at the end of each of its movements, combined with the sectional plunger adapted to the pockets or molds of said table for pressing the filler-tobacco through the same, means for operating said sectional plunger, rolling mechanism, and means for conveying the filler-tobacco pressed through said molds to said rolling mechanism; substantially as set forth.

2. In a cigar-bunching machine, the rotary feed-table having the series of pockets or molds for receiving the filler-tobacco, means for imparting an intermittent rotary motion to said table, and means for locking said table at the end of each of its movements, combined with the sectional plunger adapted to the pockets or molds of said table for pressing the filler-tobacco through the same, the series of knife-blades carried below said table for severing the surplus filler-tobacco in said molds from that portion thereof intended for the bunches, means for maintaining said knife-blades below said molds to close the latter at their lower end except when one of said molds is below said plunger, means for operating said knife-blades when below said plunger for first withdrawing the knife-blade from below the mold and then driving it outward to its former position to enable said knife-blade to sever the filler-tobacco and again close the lower end of the mold, means for operating said sectional plunger, and rolling mechanism to receive the filler-tobacco pressed through said molds and below said blades, the surplus tobacco remaining within said molds above said blades; substantially as set forth.

3. In a cigar-bunching machine, the rotary feed-table having the series of pockets or molds for receiving the filler-tobacco, means for imparting an intermittent rotary motion to said table, and means for locking said table at the end of each of its movements, combined with the plunger adapted to the pockets or molds of said table for pressing the filler-tobacco through the same, the series of knife-blades carried below said table, means for maintaining said knife-blades below said pockets or mold for closing the lower end of the latter except when a mold and its knife-blade are below said plunger, means for withdrawing the knife-blade when below said plunger from below its pocket or mold and then driving said knife-blade outward to sever the filler-tobacco and again close the lower end of the mold, means for operating said plunger, and rolling mechanism to receive the filler-tobacco pressed through said molds and below said blades, the surplus tobacco remaining within said molds above said blades; substantially as set forth.

4. In a cigar-bunching machine, the rotary feed-table having the series of pockets or molds for receiving the filler-tobacco, and means for imparting an intermittent rotary motion to said table, combined with the plunger adapted to the pockets or molds of said table for pressing the filler-tobacco through the same, the series of knife-blades carried below said table and normally closing the lower ends of said pockets or molds, the series of rollers connected with said knife-blades, a knife-cam 106 having a groove receiving the said rollers and also having the oppositely inclined surfaces 113 and 114 for acting on said knives in succession as they pass into position below said plunger, whereby to withdraw said knife-blades in succession and then drive the same outward through the filler-tobacco pressed downward by said plunger, means for compelling said knife-cam to rotate with said table for a predetermined distance and then perform a reverse motion for carrying said surfaces 113 and 114 against the roller of the knife-blade then below said plunger, means for operating said plunger, and rolling mechanism, to receive the filler-tobacco pressed through said molds and below said blades, the surplus tobacco remaining within said molds above said blades; substantially as set forth.

5. In a cigar-bunching machine, the rotary feed-table having the series of pockets or molds for receiving the filler-tobacco, and means for imparting an intermittent rotary motion to said table, combined with the plunger adapted to the pockets or molds of said table for pressing the filler-tobacco through the same, the series of knife-blades carried below said table and normally closing the lower ends of said pockets or molds, the series of rollers connected with said knife-blades, the knife-cam 106 having a groove receiving the said rollers and also having the oppositely-inclined surfaces 113 and 114 for acting on said knives in succession as they pass into position below said plunger, whereby to withdraw said knife-blades in succession and then drive the same outward through the filler-tobacco pressed downward by said plunger, means for compelling said cam to rotate with said table for a predetermined distance and then to perform a reverse rotation in two divisions to its former position whereby said cam during the first part of its reverse motion will bring one of said inclined surfaces against the roller of the knife-blade below the plunger and then, after a stoppage, carry the other inclined surface against said roller while performing the second division of its reverse rotation, means for operating said plunger, and rolling mechanism, to receive the filler-tobacco pressed through said molds and below said blades, the surplus tobacco remaining within said molds above said blades; substantially as set forth.

6. In a cigar-bunching machine, the rotary feed-table having the series of pockets or molds for receiving the filler-tobacco, the plate 101 secured to said table and having the series of radial slots 104 corresponding in number with said molds, the crank-arm 126 having the roller 127 adapted to enter said slots and effect the intermittent rotation of said plate and said feed-table, and means for turning said crank-arm 126 to perform a complete rotation, whereby upon said roller 127 emerging from one of said slots, it may be enabled to rotate to another one thereof, said plate and said table remaining in stationary position during the travel of said

roller 127 from one slot to another of said plate, combined with the plunger adapted to the pockets or molds of said table for pressing the filler-tobacco through the same, means for operating said plunger, and rolling mechanism; substantially as set forth.

7. In a cigar-bunching machine, the rotary feed-table having the series of pockets or molds for receiving the filler-tobacco, the plate 101 connected with said table and having the series of radial slots 104 corresponding in number with the said pockets or molds and also having intermediate said slots the recesses 129, crank-arm 126 having the roller 127 adapted to enter and travel within the aforesaid slots, means for turning said crank-arm 126 to compel said roller to enter said slots and impart an intermittent motion to said plate and said table, and the flange 128 connected with said crank-arm for moving in and engaging said recesses during the period that said roller 127 is free of said plate whereby to lock said plate and said table at the end of each of their intermittent motions, combined with the plunger for pressing the filler-tobacco through the said pockets or molds, means for operating said plunger, and rolling mechanism; substantially as set forth.

8. In a cigar-bunching machine, the rotary feed-table having the series of pockets or molds for receiving the filler-tobacco, and means for imparting an intermittent rotary motion to said table, combined with the series of plungers 105 constituting a sectional plunger adapted to the said pockets or molds, the independent rods 131 carrying said plungers, the vertically-movable frame supporting and adapted to guide said rods, the blocks 136 on said rods and engaging a portion of said frame for normally maintaining said plungers in their initial position, the pivoted levers 142 at one end engaging said blocks and at their other end having the recessed edges, the series of springs 139 fastened at their upper end to said frame and at their lower end carrying the stirrups 141 in engagement with the recessed end of said levers for yieldingly pressing the said plungers downward, and rolling mechanism, the said stirrups being adjustable along said levers for independently regulating the tension of said springs; substantially as set forth.

9. In a cigar-bunching machine, a feed-table having a mold or pocket to receive the filler-tobacco, a knife-blade below and normally closing said pocket at its lower end, the series of plungers 105 forming a sectional plunger adapted to said mold or pocket, the independent rods 131 carrying said plungers, the vertically-movable frame supporting and guiding said rods, the blocks 136 on said rods and engaging a portion of said frame, the pivoted levers 142 at one end engaging said blocks, the series of springs 139 engaging the other end of said levers for causing the latter to exert downward pressure against said blocks, and means for moving said frame and plungers in a vertical direction, combined with means for actuating said knife-blade to sever the surplus filler-tobacco placed in said mold or pocket, rolling mechanism, and means for conveying the filler-tobacco pressed through said mold or pocket by said plungers to said rolling mechanism; substantially as set forth.

10. In a cigar-bunching machine, a feed-table having a mold or pocket to receive the filler-tobacco, a knife-blade below and normally closing said pocket at its lower end, the series of plungers 105 forming a sectional plunger adapted to said mold or pocket, the independent rods 131 carrying said plungers, the vertically-movable frame supporting and guiding said rods, the blocks 136 on said rods and engaging a portion of said frame, the pivoted levers 142 at one end engaging said blocks, the series of springs 139 engaging the other end of said levers for causing the latter to exert downward pressure against said blocks, means for independently adjusting the tension of said springs for independently regulating the pressure to be exerted by said plungers, means for moving said frame carrying said plungers in a vertical direction, combined with means for actuating said knife-blade to sever the surplus filler-tobacco placed in said mold or pocket, rolling mechanism, and means for conveying the filler-tobacco pressed through said mold or pocket by said plungers to said rolling mechanism; substantially as set forth.

11. In a cigar-bunching machine, a feed-table having a pocket or mold to receive the filler-tobacco, a plunger for pressing the filler-tobacco through said mold, rolling mechanism for rolling the bunch, and a receiver for receiving the charge of filler-tobacco pressed through said mold and conveying the same to the said rolling mechanism, said receiver comprising the frame 169, a plunger 172 forming the bottom of the cavity in the said receiver, and hinged lids 178 for closing over the upper end of said receiver after the filler-tobacco is therein, combined with the shaft 153 upon which said receiver is mounted, a vertically-movable frame carrying said shaft 153, the racks 168 connected with said plunger 172, the gear-wheels 167 on said shaft for engaging said racks and moving said plunger, means for rotating said shaft to turn said wheels 167, the sleeve 184 on said shaft and connected at one end to said receiver and at the other end having a gear-wheel 185, means for engaging said gear-wheel 185 for turning the same and reversing the said receiver, the sleeve 181 on said sleeve 184 and having at its ends the gear-wheels 180, 182, respectively, gears connected with said lids and in engagement with said gear-wheel 180 to be operated by the latter for opening and closing said lids, and means connected with said gear-wheel 182 for turning the same and effecting thereby the rotation of said gear-wheel 180 and the opening and closing of said lids; substantially as set forth.

12. In a cigar-bunching machine, the feed-table having a pocket or mold approximately in the outline of a cigar to receive the filler-tobacco, a plunger approximately in the outline of a cigar for pressing the filler-tobacco through said mold, rolling mechanism for rolling the bunch, and a receiver having a cavity approximately in the outline of a cigar for receiving the charge of filler-tobacco pressed through said mold and conveying the same to the said rolling mechanism, said receiver comprising the exterior casing or frame 169, the plunger 172 forming the bottom of the cavity in said receiver and being approximately in the outline of a cigar, and the lids for closing over the upper end of said receiver after the filler-tobacco is therein, combined with the vertically-movable frame carrying said receiver, means for moving said frame, means for opening and closing said lids, means for reversing said receiver during its vertical movement, and means for actuating the plunger within said receiver; substantially as set forth.

13. The rotary feed-table having the pockets or molds for receiving the filler-tobacco, means for imparting an intermittent rotary motion to said table, a plunger adapted to the said pockets or molds for pressing the filler-tobacco through the same, rolling mechanism, and means for conveying the filler-tobacco pressed through said molds to said rolling mechanism, said rolling mechanism comprising the flexible apron 208, a rolling-table upon which said apron is arranged, the roller 212 to which one end of said apron is connected, and a pressure-blade 214 mounted to travel with and follow said roller and to engage the loop to be formed in said apron, combined with a slidable frame carrying said roller and blade, means for moving said frame, means for preventing the rotation of said roller 212 until after said blade has passed over the loop to be formed in said apron around the filler-tobacco, means for then giving said roller a rapid rotation for winding up said apron and drawing said loop down to rise against the edge of said blade, and means for then imparting a substantially uniform and less rapid rotation to said roller 212 during its continued outward travel for gradually winding up said apron; substantially as set forth.

14. The rotary feed-table having the pockets or molds for receiving the filler-tobacco, means for imparting an intermittent rotary motion to said table, a plunger adapted to said pockets or molds for pressing the filler-tobacco through the same, rolling mechanism, and means for conveying the filler-tobacco pressed through said molds to said rolling mechanism, said rolling mechanism comprising the flexible apron 208, a rolling-table upon which said apron is arranged, the roller 212 to which one end of said apron is connected, the pressure-blade 214 mounted to travel with and follow said roller and to engage the loop to be formed in said apron, and a spring exerting its force against said blade in a direction opposed to the direction of travel of said blade during the rolling of a bunch, combined with a slidable frame carrying said roller and blade, means for moving said frame and means for taking up the slack in said apron; substantially as set forth.

15. The rotary feed-table having the pockets or molds for receiving the filler-tobacco, means for imparting an intermittent rotary motion to said table, a plunger adapted to the said pockets or molds for pressing the filler-tobacco through the same, rolling mechanism, and means for conveying the filler-tobacco pressed through said molds to said rolling mechanism, said rolling mechanism comprising the flexible apron 208, a rolling-table upon which said apron is arranged, the roller 212 to which one end of said apron is connected, and a pressure blade 214 mounted to travel with and follow said roller and to engage the loop to be formed in said apron, combined with a slidable frame carrying said roller and blade, means for moving said frame, the gear-wheel 246 connected with said roller, the gear-wheel 248 indirectly geared to said wheel 246 and having the locking-plate 249, the rack-bar 245 having the upper teeth 251 to engage said gear-wheel 246 and also the flat plate 250 to engage said locking-plate 249 and also the lower gear-teeth 253, the segment 252 for engaging said teeth 253 of said rack-bar, and means for actuating said segment to shift said rack-bar for causing said roller to wind up said apron and draw the loop therein down to rise against said pressure-blade, said locking-plate 249 during the first portion of the outward travel of the roller 212 being in engagement with the said plate 250 and preventing the rotation of said roller, and thereafter leaving said flat plate 250 and enabling the teeth 251 of said rack-bar to engage said gear-wheel 246, the latter being then permitted to rotate and to effect the rotation of said roller 212; substantially as set forth.

16. The rotary feed-table having the pockets or molds for receiving the filler-tobacco, means for imparting an intermittent rotary motion to said table, a plunger adapted to said pockets or molds for pressing the filler-tobacco through the same, rolling mechanism, and means for conveying the filler-tobacco pressed through said molds to said rolling mech-

anism, said rolling mechanism comprising the flexible apron 209, a rolling-table upon which said apron is arranged, the roller 212 to which one end of said apron is connected, the pressure-blade 214 mounted to travel with and follow said roller and to engage the loop to be formed in said apron, and means for exerting a yielding force against said blade in a direction opposed to the direction of travel of said blade during the rolling of a bunch, combined with a slidable frame carrying said roller and blade, means for moving said frame, and means for taking up the slack in said apron; substantially as set forth.

17. In a cigar-bunching machine, a feed-table having a pocket or mold to receive the filler-tobacco, a plunger for pressing the filler-tobacco through said mold, rolling mechanism, and means for conveying the filler-tobacco pressed through said mold to said rolling mechanism, said rolling mechanism comprising the flexible apron 209, a rolling-table upon which said apron is arranged, the roller 212 to which one end of said apron is connected, the pressure-blade 214 mounted to travel with said roller and to engage the loop to be formed in said apron, and means for exerting a yielding force against said blade in a direction opposed to the direction of travel of said blade during the rolling of a bunch, combined with a slidable frame carrying said roller and blade, means for moving said frame, the adjusting-screws and stops for regulating the initial position of said blade with respect to said roller, and means for taking up the slack in said apron; substantially as set forth.

18. In a cigar-bunching machine, a feed-table having a pocket or mold to receive the filler-tobacco, a plunger for pressing the filler-tobacco through said mold, rolling mechanism, and means for conveying the filler-tobacco pressed through said mold to said rolling mechanism, said rolling mechanism comprising the flexible apron 209, a rolling-table upon which said apron is arranged, the roller 212 to which one end of said apron is connected, the pressure-blade 214 mounted to travel with said roller and to engage the loop to be formed in said apron, and means for exerting a yielding force against said blade in a direction opposed to the direction of travel of said blade during the rolling of a bunch, combined with the slidable frame comprising the sides 223 carrying said roller, the transverse frame 238 connecting said sides, the studs secured to said blade and guided in apertures in said frame 238, adjusting means for regulating the initial position of said blade with respect to said roller, and means for moving the said frame carrying said roller and blade; substantially as set forth.

19. In a cigar-bunching machine, a feed-table having a pocket or mold to receive the filler-tobacco, a plunger for pressing the filler-tobacco through said mold, rolling mechanism, and means for conveying the filler-tobacco pressed through said mold to said rolling mechanism, said rolling mechanism comprising the flexible apron 209, a rolling-table upon which said apron is arranged, the roller 212 to which one end of said apron is connected, the pressure-blade 214 mounted to travel with said roller and to engage the loop to be formed in said apron, and means for exerting a yielding force against said blade in a direction opposed to the direction of travel of said blade during the rolling of a bunch, combined with the slidable frame carrying said roller and comprising the sides 223 having the toothed lower edges, the transverse frame 238 connecting said sides, the studs connected with said blade and guided in said frame 238, adjusting means for regulating the initial position of said blade with respect to said roller, means for taking up the slack in said apron, and driving-gear engaging the lower toothed edges of said sides for moving the same and the parts carried thereby; substantially as set forth.

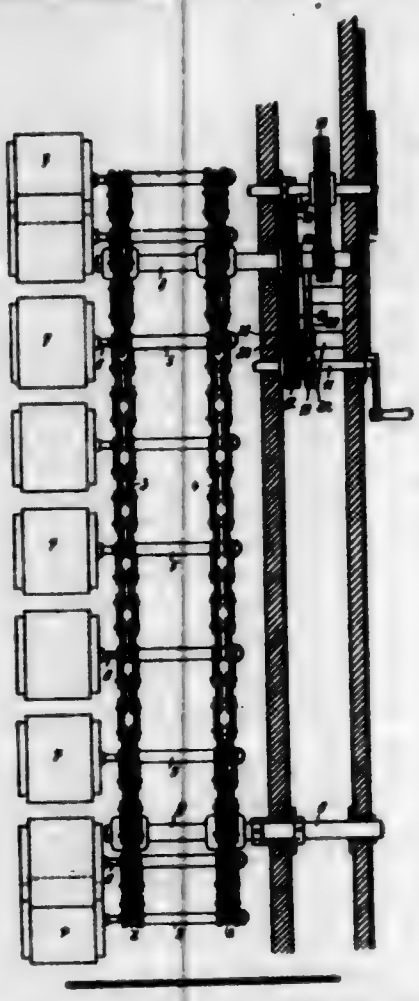
20. In a cigar-bunching machine, a feed-table having a pocket or mold to receive the filler-tobacco, a plunger for pressing the filler-tobacco through said mold, rolling mechanism, and means for conveying the filler-tobacco pressed through said mold to said rolling mechanism, said rolling mechanism comprising the flexible apron 209, a rolling-table upon which said apron is arranged, the roller 212 to which one end of said apron is connected, the pressure-blade 214 mounted to travel with said roller and to engage the loop to be formed in said apron, the belt 215 below said apron, and means for moving said belt in a direction reversely to that taken by said apron during the rolling of a bunch, combined with a slidable frame carrying said roller and blade, means for moving said frame, and means for taking up the slack in said apron; substantially as set forth.

707,749. PHONOGRAPH. HEINRICH WIENHAHN, BRUNSWICK, Germany. Filed Nov. 19, 1901. Serial No. 82,961. (No model.)

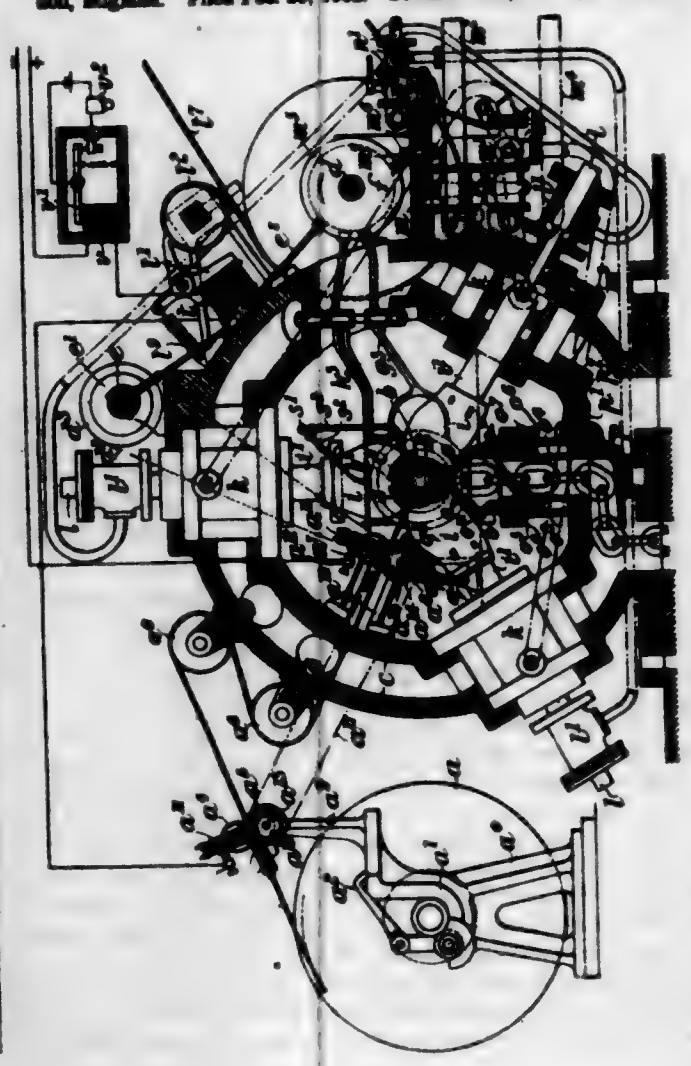
Claim.—1. A phonograph provided with a pair of endless chains, a series of connecting-bolts extending with one end laterally beyond the chains, and with cylinders mounted upon such laterally-projecting bolt ends, substantially as specified.

2. A phonograph provided with a pair of endless chains, a series of connecting-bolts extending with one end laterally beyond the chains, cylinders mounted upon the laterally-projecting bolt ends, a crank-shaft for rotating the chains, and an index intergeared with the crank-shaft, substantially as specified.

3. A phonograph provided with a pair of endless chains, a series of connecting-bolts extending with one end laterally beyond the chains, cylinders mounted upon the laterally-projecting bolt ends, a crank-shaft for rotating the chains, a notched disk mounted upon said shaft, a lever having a projection adapted to engage the disk, and an arm on the lever adapted to arrest the running-gear of the phonograph, substantially as specified.



707,750. MACHINE FOR MAKING CHAIN. LUIS WERTH, London, England. Filed Feb. 25, 1902. Serial No. 95,587. (No model.)



Claim.—1. In a machine for the manufacture of chain, the combination of wire-feeding mechanism, of a grooved die on which the wire is coiled, of means for rotating the die, of a series of outer dies for entering the groove and pressing the coils so as to weld them together to form a link and means for operating the dies, substantially as described.

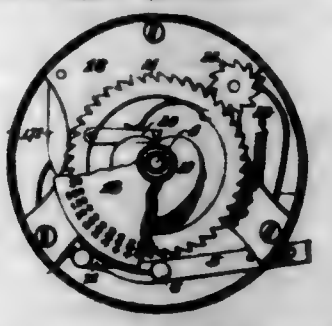
2. In a machine for the manufacture of chain, the combination of means for heating wire, of a grooved die onto which the heated wire is coiled, the said die being in halves to release the link subsequently formed thereon, of means for moving the halves relatively, of means for rotating the die, of a series of outer dies for entering the groove and pressing the coils so as to weld them together to form a link, of means for operating the said outer dies, of rams or supports for the halves of the die while the pressure is being exerted and of means for operating them substantially as described.

3. In a machine for the manufacture of chain the combination of means for heating a wire and feeding the same to a grooved die on which the heated wire is coiled, the said die being in halves to release the link subsequently formed thereon and having slots to embrace the last-formed link, of means for moving the halves of the die relatively, of means for rotating the die, of a series of outer dies for entering the groove and pressing the coils so as to weld them together to form a link, of means for operating the said outer dies, of rams or supports for the halves of the die while the pressure is being exerted, the said rams having projections for entering the slots in the grooved die, and of means for operating the said rams, substantially as described.

4. In a machine for the manufacture of chain the combination of means for electrically heating a wire, and for feeding the same, of a grooved die on which the heated wire is coiled, the said die being in halves to release the link subsequently formed thereon and having slots to embrace the last-formed link, of means for rotating the die, of a series of outer dies for entering the groove and pressing the coils so as to weld them together to form a link, of means for operating the said outer dies, of rams or supports for the halves of the die while the pressure is being exerted, the said rams having projections for entering the slots in the grooved die, of means for operating the said rams, of a support for receiving the finished link and turning and lowering it into position to be engaged by the next formed link and of means for operating the support, substantially as described.

5. In a machine for the manufacture of chain the combination of means for electrically heating a wire and for feeding the same, of a grooved die on which the heated wire is coiled, the said die being formed in halves to release the link subsequently formed thereon and with slots to embrace the last-formed link, of means for moving the halves of the die relatively, of means for rotating the die, of a series of outer dies for entering the groove and pressing the coils so as to weld them together to form a link, of means for operating the said outer dies, of rams or supports for the halves of the die while the pressure is being exerted, the said rams having projections for entering the slots in the grooved die, of means for operating the said rams, of a support for receiving the finished link and turning and lowering it into position to be engaged by the next formed link, of means for operating the said support, of a table to receive the chain as it is formed and turn it to correspond with the movement of the last-formed link and of means for turning the table, substantially as described.

707,751. **REGISTER.** JESSE ALEXANDER, Brooklyn, N. Y., assignor of one-half to Harsden S. Skidmore, Brooklyn, N. Y. Filed Dec 20, 1901. Serial No. 86,626. (No model.)



Claim.—1. In a registering apparatus, a pointer adapted to traverse a series of unit graduations, a disk having a sleeve extended therefrom and revolubly mounted upon a central arbor said pointer being carried by said sleeve, a toothed wheel lying adjacent to said disk, and means intermediate of the disk and the wheel for engaging said parts when said parts are close to each other, and means for moving one of said parts away from the other to disengage the same, and a lever for actuating said toothed wheel, and a pawl between the said lever and said toothed wheel, said pawl having a forward extension for actuating and advancing said wheel, and a rearward extension for checking said wheel to prevent its overrunning.

2. In a registering apparatus, a stationary units-dial, and graduations thereon, a rotatable internal dial below said stationary dial, and multiples of said units thereon, an opening in the stationary dial directly above the multiple graduations on the inner dial, a central arbor carrying a toothed wheel, a disk above said toothed wheel and loosely mounted on said central arbor, a sleeve carried by said disk and extended to a point above the stationary dial, a shoulder on said sleeve, a stationary internal frame, a tension-frame loosely mounted upon said sleeve and a spring between said tension-frame and said disk one end of said spring being fastened to said tension-frame and the other end to said disk, and means for letting down the tension of said spring step by step.

3. In a registering apparatus, a stationary dial having a window therein and a rotatable dial beneath the same, a central arbor, a sleeve revolubly mounted thereon, an index-hand or pointer on said sleeve, reversing devices for said sleeve and dial, movable connections between the same, a toothed wheel connected to the arbor and means for rotating said toothed wheel step by step to increase the tension of the reversing devices, and means for disconnecting said wheel from said tension devices, substantially as described.

4. In a registering device, a dial, a sleeve centrally mounted relatively thereto, a pointer carried thereby, a shoulder on said sleeve bearing against the under side of a stationary part, a disk at the lower end of said sleeve, a tension frame and spring between the stationary part and said disk, a toothed wheel loosely mounted on said sleeve, an internal dial carried by said toothed wheel, a central spindle loosely projecting through said sleeve and bearing a toothed wheel at its lower end, and means for detachably engaging said toothed wheel with said lower disk, an operating-lever and a two-armed pawl for actuating and checking the movement of the lower toothed wheel and its associated parts, and a countershaft bearing a gear in engagement with the toothed wheel on the internal dial, and another toothed wheel arranged adjacent to the lower disk when in normal position, and a tooth on said lower disk, all arranged substantially as and for the purpose described.

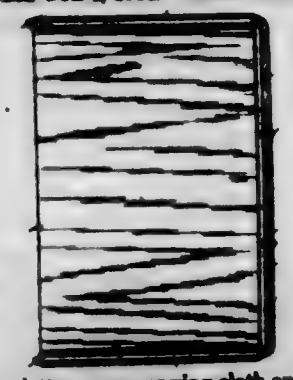
5. In a registering apparatus, a stationary dial bearing units-marks, a movable dial bearing marks indicating multiples of said units, a pointer and means for causing the same to traverse the stationary dial, and means for causing the internal dial to advance one step at each complete revolution of the pointer, a tension-frame and spring-actuated means to turn all of said parts back to the zero position, and means to separate the parts adjacent to said springs to afford freedom of action.

707,752. **MANUFACTURE OF SHEETS OF FLEXIBLE ELASTIC MATERIAL WHICH CANNOT BE READILY PUNCTURED.** VICTOR E. BELLEMÈRE, Paris, France. Filed Mar. 29, 1901. Serial No. 53,093. (No specimens.)

Claim.—1. The process herein described of making sheets of flexible elastic material, which comprises the steps of cleaning and dehairing the hide of a suitable animal, immersing said hide in a bath of cold crude petroleum, then immersing the same in a bath of mineral or fatty oil, permitting the hide to dry, cutting from said hide a sheet of suitable width, curling and curving said sheet, immersing the same in benzin, immersing the same in a bath of chlorid of lime, drying the sheet, and immersing the same in a solution of caoutchouc in benzin, substantially as set forth.

2. The process herein described of making sheets of flexible elastic material, which comprises the steps of cleaning and dehairing the hide of a suitable animal, immersing said hide in a bath of cold crude petroleum, then immersing the same in a bath of mineral or fatty oil, permitting the hide to dry, immersing the same in a bath of sodium or potassium silicate, cutting from said hide a sheet of suitable width, curling and curving said sheet, immersing the same in benzin, immersing the same in a bath of chlorid of lime, drying the sheet, immersing the same in a solution of caoutchouc in benzin, substantially as set forth.

707,753. **LETTER-PRESS-COPYING CLOTH AND FRAME.** LOUIS REISSAUS, Milwaukee, Wis., assignor of one-half to Karl Mueller, Milwaukee, Wis. Filed Dec. 4, 1901. Serial No. 84,897. (No model.)



Claim.—1. In a letter-press-copying cloth and frame, the combination with a copying-cloth, of a frame comprising a main member and two

arms extending in the same direction and at angles from opposite ends of the main member, said arms having the opposite end edges of the cloth secured thereto, and the cloth drawn tight thereby, the length of the arms being such that the main member will lie parallel with and outside of the outer side edges of the leaves of the copying-press book, when the device is applied between said leaves, and the distance apart of the arms being such that said arms will lie parallel with and outside of the opposite end edges of the leaves of the book.

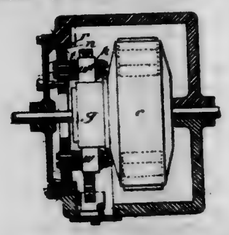
2. In a letter-press-copying cloth and frame, the combination with a copying-cloth, of a frame comprising a main member and two arms extending in the same direction and at angles from opposite ends of the main member, said arms having the opposite end edges of the cloth removably secured thereto and the cloth drawn tight thereby, the length of the arms being such that the main member will lie parallel with and outside of the outer side edges of the leaves of the copying-press book, when the device is applied between said leaves, and the distance apart of the arms being such that said arms will lie parallel with and outside of the end edges of the leaves of the book.

3. In a letter-press-copying cloth and frame, the combination with a copying-cloth having its opposite end edges provided with loops, of a frame comprising a main member and two arms extending in the same direction and at angles from opposite ends of the main member, said arms adapted to have the end loops of the cloth removably fitted thereon and the cloth drawn tight thereby, the length of the arms being such that the main member will lie parallel with and outside of the outer side edges of the leaves of the copying-press book, when the device is applied between said leaves, and the distance apart of the arms being such that said arms will lie parallel with and outside of the end edges of the leaves of the book.

4. In a letter-press-copying cloth and frame, the combination of a frame comprising a main member consisting of two sections extensibly fitted together, and each section having an arm extending therefrom at an angle, means for holding the sections of the main member in adjusted position, and a copying-cloth secured at opposite end edges of the arms.

5. In a letter-press-copying cloth and frame, the combination of a frame comprising a main member consisting of two sections slidably fitted together, and each section provided with apertures, any two of which may be brought into registration, and each section also provided with an arm extending at an angle therefrom, a pin adapted to be fitted in the registering apertures to thereby hold the sections in adjusted position, and a copying-cloth secured at opposite end edges to the arm.

707,754. BRUSH MECHANISM FOR DYNAMOS. WILLIAM L. RAE, Brooklyn, N. Y., assignor to Rae Electric Car Lighting Company, New York, N. Y., a Corporation of New Jersey. Filed Feb. 3, 1902. Serial No. 92,692. (No model.)



Claim.—1. The combination with a rotary armature and commutator, of brush-holders, a rocking support for the brush-holders and a removable stop for limiting the rocking movement of said support, substantially as set forth.

2. In a brush mechanism for dynamos, a rotating member, brush-holders provided with brushes, a rocking support for the said brush-holders, means for transmitting a rotatory movement to said support from said rotating member, and a removable stop for limiting the rotatory movement of said support, substantially as set forth.

3. In a brush mechanism for dynamos, a rotating member, brush-holders provided with brushes, a rocking support for said brush-holders, means for transmitting a rotatory movement to said support from said rotating member, and a removable stop for limiting the rotatory movement of the said support in each of two opposite directions, substantially as set forth.

4. The combination with a casing provided with an opening in its base and a rotary armature and commutator mounted within the casing, of brush-holders, a rocking support for the brush-holders and a removable stop for limiting the rocking movement of the said support whereby access to the several brush-holders and brushes may be obtained through the bottom of the casing, substantially as set forth.

5. Brush mechanism for dynamos comprising a ring, rolling bearings at the periphery of the ring, brush-holders carried by the ring and means for limiting the rotary movement of the ring in each of two opposite directions, substantially as set forth.

6. Brush mechanism for dynamos comprising a rotary ring, a stationary ring, a raceway intermediate of the two rings, bearing-balls located in said raceway and serving to hold the rings in rotatable relation with each other, brush-holders carried by the rotary ring and means for limiting the rotatory movement of the said rotary ring, substantially as set forth.

7. Brush mechanism for dynamos comprising an inner rotary ring, an outer stationary ring, a raceway intermediate of the two rings, bearing-balls located in said raceway, brush-holders carried by the inner ring and means for limiting the rotary movement of the inner ring in each of two opposite directions, substantially as set forth.

8. A brush mechanism for dynamos comprising a stationary outer ring, a rotary inner ring, a raceway intermediate of the two rings, bearing-balls located in said raceway and serving to hold the inner ring in position within the outer ring, brush-holders carried by the said inner ring and means for limiting the rocking movement of the inner ring in each of two opposite directions, substantially as set forth.

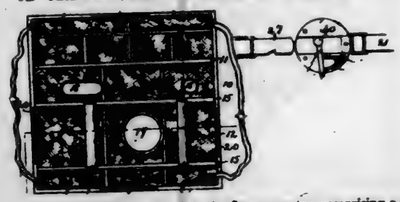
9. The brush mechanism for a dynamo comprising an outer ring provided with one part of a raceway in its inner face, a hole leading from the exterior surface of the ring to the part raceway, means for plugging the hole to complete the wall of the raceway, an inner ring fitted to rotate within the outer ring and provided with part of a raceway in its periphery, bearing-balls located in the raceway and serving to hold the inner ring in position with respect to the outer ring, brush-supports carried by the inner ring and means for limiting the rocking movement of the inner ring, substantially as set forth.

10. The combination with a casing and a rotary armature and commutator mounted within the casing, of an outer stationary ring fitted in an opening at the front of the casing, a removable cover for closing the opening in front of the casing, an inner ring fitted to rotate within the said outer ring, the said inner and outer rings being each formed on their adjacent faces with parts of a raceway, bearing-balls serving to hold the inner ring in position within the outer ring and means for limiting the rocking movement of the inner ring, substantially as set forth.

11. The combination with a casing and a rotary armature and commutator mounted within the casing, of an outer stationary ring fitted in an opening at the front of the casing, a removable cover for closing the opening in the front of the casing, an inner ring fitted to rotate within the said outer ring, the said inner and outer rings being each formed on their adjacent faces with parts of a raceway, bearing-balls serving to hold the inner ring in position within the outer ring and a stop carried by the said removable cover for limiting the rocking movement of the inner ring, substantially as set forth.

12. The combination with a casing provided with an open front and an opening in its base, of a rotary armature and commutator mounted within the casing, a removable cover for the front of the casing and provided with a bearing for the armature and commutator and shaft, a removable plate forming a cover for the opening in the base of the casing, an outer stationary ring fixed in the opening at the front of the casing, an inner rocking ring mounted within the outer stationary ring, brush-holders carried by the inner rocking ring in position to be manipulated through the opening in the base of the casing and a removable stop for limiting the rocking movement of the inner ring, substantially as set forth.

707,755. LUGGAGE-CARRIER. JAMES A. BRITTON, Bethlehem, Pa. Filed Oct. 17, 1901. Serial No. 78,908. (No model.)



Claim.—1. A luggage-carrier for fire apparatus comprising a metallic framework, the top bars of which are provided with loops, and securing-straps connected to said framework and arranged to coact with said loops, as set forth.

2. A luggage-carrier for fire apparatus comprising a framework, the top bars of which are provided with loops, securing-straps attached to said framework and arranged to coact with said loops, and means for detachably connecting the free ends of said straps, as set forth.

3. A luggage-carrier comprising a framework forming a deep receptacle the bottom of which is curved to form a shallow extension, loops arranged upon the top bars of said framework, and securing-straps connected to said framework and arranged to coact with said loops, substantially as set forth.

4. A luggage-carrier for fire apparatus comprising a framework forming a deep receptacle the bottom of which is curved to form a shallow extension, pads or cushions arranged transversely across said deep receptacle, loops arranged upon the top bars of said framework, securing-straps connected to said framework and arranged to coact with said loops, and loops or pockets secured to the sides of said framework, substantially as set forth.

5. A luggage-carrier comprising a basket or receptacle, loops formed on the top edges thereof, straps secured to said basket, plates secured to the free ends of said straps, spring-pressed catches carried by said plates, additional straps secured to juxtaposition to said former straps, and notched members carried by the free ends of said latter straps and arranged to be engaged by said catches, substantially as set forth.

707,756. SPRING KEY OR COTTER. THOMAS S. BROWN, Poughkeepsie, N. Y. Filed May 2, 1902. Serial No. 105,594. (No model.)

Claim.—1. A spring cotter comprising a pair of arms suitably united, said arms being set out edgewise the one from the other, so that each has an edge portion projecting edgewise beyond the adjacent edge of the other.

2. A spring cotter comprising a pair of arms suitably united, said arms being at their outer ends such in outline as to its external face of approximately semi-circular outline, and as to its inner face approximately flat, said arms being set out edgewise the one from the other, but adapted to be moved edgewise to a position in which their opposing edges are in registry.

3. A spring cotter consisting of a pair of arms united by a loop, said arms being set out edgewise the one with respect to the other, the outer edge of each having an elongated recess or depressed region terminating in a shoulder near the outer end of the arm.

4. A spring cotter consisting of a pair of arms united by a loop, said arms being set out edgewise the one with respect to the other, the outer edge of each having an elongated recess or depressed region terminating in a shoulder near the outer end of the arm, and which shoulder terminates, circumferentially of said arm, at a point on the back of said arm.

5. A spring cotter consisting of a pair of arms united by a loop, said arms being of approximately semi-cylindrical section, the outer edge portion of each arm having an elongated depression terminating in a circumferentially extending shoulder at its outer end, said shoulder being of increasing height from a point at the back of the arm to a point at the edge of the arm.

6. A spring cotter consisting of a pair of arms united by a loop, said arms being set out edgewise the one with respect to the other, said arms being of approximately semi-cylindrical section, the outer edge portion of each arm having an elongated depression terminating in a circumferentially extending shoulder at its outer end, said shoulder being of increasing height from a point at the back of the arm to a point at the edge of the arm, the inner edge portion of each arm in the region opposite the shoulder being of uniform dimensions from end to end of such region.

7. A spring cotter having two arms each of approximately semi-cylindrical section, suitably united, set out edgewise from each other, each throughout its body on a line perpendicular to the plane of its flat face, of a diameter approximately half the breadth of its inner flat face at the broadest portion of the latter, each as to one lateral half of its external face of uniform dimensions from end to end, and each as to the other lateral half provided with an elongated depression terminating in a shoulder in the vicinity of its outer end.

8. A spring key or cotter consisting of a pair of arms suitably united, said arms being set out edgewise the one with respect to the other, the outer edge of one arm having a recess or depressed region terminating in a shoulder near the outer end of the arm.

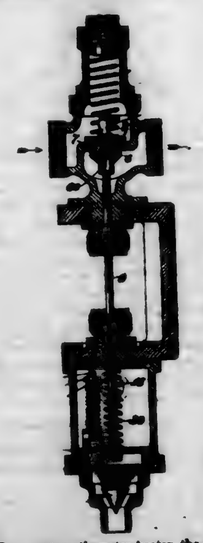
9. A spring cotter or key, consisting of a pair of arms united by a loop, said arms being set out edgewise the one with respect to the other, the outer edge of one of said arms having a recess or depressed region terminating in a shoulder near the outer end of the arm, and which shoulder terminates, circumferentially of said arm, at a point on the back of said arm.

10. A spring cotter or key consisting of a pair of arms united by a loop, said arms being set out edgewise the one with respect to the other, said arms being of approximately semi-cylindrical section, the outer edge portion of one arm having an elongated depression terminating in a circumferentially extending shoulder at its outer end, said shoulder being of increasing height from a point at the back of the arm to a point at the edge of the arm.

707,757. LOCK. HENRY REYER, Woonsocket, R. I. Filed Nov. 8, 1901. Serial No. 81,776. (No model.)

Claim.—In a lock, the combination with the casing, a sliding bolt therein having a shank provided with upper edge notches, a segmental recess formed in the face of the shank, a spring having a projecting free end arranged to slide between the rear wall of the casing and rear surface of the shank, a second spring having a shoulder and a tongue, the former seated in the notches and the latter having its terminal end mounted on the free end of the first-mentioned spring, of a key having hooks on its operating end with a space between them, said space adapted to straddle the edge of the shank below the recess to permit the hooks of the key, one of which coacts with the under surface of the free projecting end of one of the springs to raise the tongue of the other spring to disengage the shoulder thereof from the notches, the other hook of the key adapted to engage the recess in the shank so as to slide the bolt forward or rearward, substantially as specified.

707,758. VALVE MECHANISM FOR WATER-HEATERS. ARTHUR ROSENAU, Allegheny, Pa. Filed Jan. 28, 1901. Serial No. 44,331. (No model.)



Claim.—1. In an automatic water-heater, the combination of a water-receptacle having supply and discharge pipes, burners for applying heat to the receptacle, a valve controlling the flow of gas to the burners, a valve-motor arranged in the line of flow of water to and from the receptacle and adapted to be operated by variations of pressure in the distributing-pipes and mechanism interposed between the valve and motor whereby after a certain initial movement of the motor, independent of the valve, a movement is imparted to the valve by the motor, substantially as set forth.

2. In an automatic water-heater, the combination of a water-receptacle having supply and discharge pipes, burners for applying heat to the same, a valve controlling the flow of gas to the burners, means for closing the valve to a closed position, a motor for opening the valve arranged in the line of flow of water to and from the receptacle, and adapted

to be operated by variations of pressure in the distributing-pipes, means for shifting the motor in opposition to the pressure in the distributing-pipes, and means whereby after a certain initial movement the movement of the motor is imparted to the valve, substantially as set forth.

3. In an automatic water-heater, the combination of a water-receptacle having supply and discharge pipes, burners for applying heat, to the receptacle, a valve controlling the flow of gas to the burners, means for shifting the valves to closed position, a piston operating in a cylinder arranged in the line of flow of water to and from the receptacle, said piston being operated in one direction by a flow of water through the cylinder, means for shifting the piston in the opposite direction against the pressure of water in the distributing-pipes and a rod extending from the piston to open the valve, said rod being constructed to permit an initial movement of the piston independent of the valve, substantially as set forth.

4. A water-distributing system for houses, &c., having in combination, a supply-pipe, a cold-water pipe provided with faucets connected to the supply-pipe, a water-receptacle connected to the supply-pipe, a pipe provided with faucets extending from the receptacle, burners for applying heat to the receptacle, a valve controlling the flow of gas to the burners, a valve-motor arranged in the line of flow of water to or from the receptacle and adapted to be operated by variations of pressure in the distributing-pipes, and mechanism interposed between the valve and motor whereby after a certain initial movement of the motor independent of the valve a movement is imparted to the valve by the motor, substantially as set forth.

707,759. **BOB-REFILLABLE BOTTLE.** EDWARD BURKE, Kearney, Neb. Filed Jan. 20, 1902. Serial No. 91,594. (No model.)

Claim.—1. In combination with a bottle or like package, a detector, and an inflatable suspending device connecting the detector with the cork, substantially as set forth.

2. In combination with a bottle or like package, a detector, and an expansible bulb forming a part of suspending means connecting the detector with the cork, substantially as set forth.

3. In combination with a bottle or like package, a detector for suspension therein, the same comprising a ring and a plurality of wires pivoted intermediate of the ends to the lower portion of one side of the ring and having an end of each made heavier to cause the wires to assume a horizontal position, the light ends of the said wires adapted to abut against the opposite side of the ring, substantially as set forth.

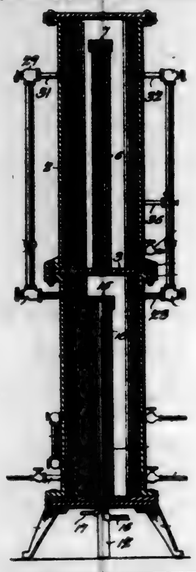
4. In combination with a bottle or like package, a detector comprising a series of pivoted wires, a cooling-cork having an extracting-loop, and suspending means between the detector and cork comprising an inflated bulb, substantially as set forth.

707,760. **OIL HEATER, STRAINER, AND SEPARATOR.** EDGAR A. BURROW, Rice, Tex. Filed Feb. 21, 1902. Serial No. 95,139. (No model.)

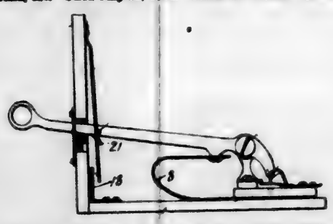
Claim.—1. An apparatus of the character specified, comprising a receiving or purifying chamber, heating means arranged therein, a storage or supply chamber, a pressure-chamber arranged in the last-named chamber and communicating with the receiving-chamber, connections between the receiving and storage chambers, and pressure-indicating means connected with the pressure-chamber.

2. An apparatus of the character specified, comprising a purifying-chamber, heating means arranged therein, means for supplying oil and water to the purifying-chamber, a storage-chamber, a pressure-chamber arranged in the last-named chamber and communicating with the purifying-chamber, and a pipe including straining means connecting the purifying and storage chambers.

3. An apparatus of the character specified comprising a purifying-chamber having a bottom provided with an opening, a heating-chamber secured in the opening and having its upper end closed, a closed-top storage-chamber supported by the purifying-chamber and separated therefrom by a plate having an opening, a pressure-chamber having its lower end secured in the opening and communicating with the purifying-chamber and its upper end closed, connections between the purifying and storage chambers, and a pressure-gage operatively connected with the pressure-chamber.



707,761. **CIRCUIT-CLOSING DEVICE.** ALBERT B. CRANDE, Centralia, Mo. Filed July 26, 1901. Serial No. 69,673. (No model.)

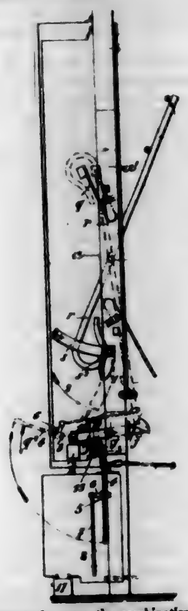


Claim.—A circuit-closing device comprising a terminal, a vertically-disposed spring-metal contact-strip secured at one end and having its free end arranged normally out of engagement with the terminal and adapted to be moved into contact therewith, a pivoted switch-lever having a long arm and a short arm, a spring acting on the long arm of the lever for normally forcing said arm upwardly, an obliquely-disposed contact-piece fixed to the strip and projecting beyond the front and rear sides of the strip, the upper and lower surfaces thereof forming reversely-inclined cams, and a contact member upon the long arm of the switch-lever adapted, when the long arm of the lever is depressed, to ride over the upper cam-surface to force the free end of the strip into engagement with the terminal, and, when said lever swings upwardly, to ride over the lower cam-surface to force the contact-piece out of the way, allowing said contact member to close said contact-piece without impediment, the resiliency of the strip causing the free end thereof to spring out of engagement with the terminal upon the disengagement of said contact piece and member, substantially as specified.

707,762. **STARTING-GATE FOR RACES.** JOSEPH P. CHEHANAL, Chantilly, France. Filed Feb. 6, 1902. Serial No. 92,732. (No model.)

Claim.—1. In a starting-gate for races, the combination of supporting-posts, a gate having arms pivotally mounted adjacent to their centers on said posts, springs oppositely disposed on each side of the pivotal centers of said arms, tilting levers having detents, lever mechanisms for bringing the gate into engagement with said detents against the tension of said springs, and means for releasing said detents, substantially as set forth.

2. In a starting-gate for races, the combination of supporting-posts, a gate having weighted arms fulcrumed adjacent to their centers, springs oppositely disposed on each side of the fulcrumed centers of said arms and secured on said supporting-posts, means for locking the gate in closed position, means for releasing the arms, pivotally-mounted cushion-frames on said posts, and means on said cushion-frames for locking the gate in open position, substantially as set forth.



3. In a starting-gate for races, the combination of supporting-posts, a gate having arms pivotally mounted adjacent to their centers on said posts, springs oppositely disposed on each side of the pivotal centers of said arms, tilting levers having detents, lever mechanisms for bringing the gate into engagement with said detents against the tension of said springs, levers for actuating said tilting levers, and suitable electrical devices for actuating said last-mentioned levers, substantially as set forth.

707,763. **ELECTROMAGNETIC SWITCH.** JOHN L. CHEVALIER, New York, N. Y., assignor to Safety Car Heating & Lighting Company, a Corporation of New Jersey. Filed Nov. 16, 1901. Serial No. 83,716. (No model.)

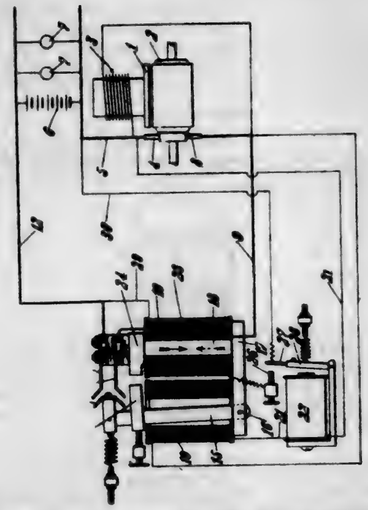
Claim.—1. An electromagnetic switch including a coil receiving current from a generator, a coil adapted to receive current from a battery, the said coils being on opposite sides of an air-gap and serving to set up a plurality of fluxes diverging at the air-gap, and a device controlled from the generator for allowing means for the passage of current through the battery-coil at predetermined times.

2. An electromagnetic switch having an air-gap and adapted to close the generator-circuit and comprising in its structure a plurality of coils adapted to receive current from a generator, one of the said coils tending to set up a flux on one side of the air-gap, a coil adapted to receive current from a battery and tending to set up a flux on the other side of the air-gap, and means controlled by the generator for manipulating the circuit of the battery-coil.

3. An electromagnetic switch having a permanent air-gap and comprising in its structure a generator-coil and a battery-coil, each tending separately to set up a flux through the magnetic circuit, and whose joint effort is to set up fluxes on opposite sides of the air-gap, which fluxes diverge at the air-gap.

4. An electromagnetic switch having a permanent air-gap comprising in its structure a generator-coil and a battery-coil, each tending separately to set up a flux through the magnetic circuit, and whose joint effort is to set up fluxes on opposite sides of the air-gap, whereby the fluxes diverge at the air-gap, and means for controlling the battery-switch coil.

5. In a system of electrical distribution, the combination of a generator and battery, and electromagnetic means for controlling a circuit, comprising a generator-switch coil, a battery-switch coil whose joint effort is to set up fluxes on opposite sides of the air-gap, and diverging at the air-gap, and automatic means for manipulating the circuit of the battery-switch coil.



6. In a system of electrical distribution, the combination of a generator and battery, with a switch having a permanent air-gap, a coil in shunt to the generator, a coil in shunt to the battery and opposing the first-named coil, and whose joint effort is to set up fluxes on opposite sides of the air-gap, and diverging at the air-gap, a coil in series with the generator, and means for manipulating the current through the said coil, so that the said coil will oppose the battery-coil when current flows from the generator to the battery, and will aid the battery-coil when current flows from the battery to the armature of the generator.

7. In a system of electrical distribution, the combination of a generator and battery, an electromagnetic switch having a permanent air-gap and receiving current from the generator and the battery, the influence of said currents setting up separate magnetic fluxes on opposite sides of the permanent air-gap in the magnetic circuit of said switch.

8. A main switch containing a magnetic circuit of high permeability, and an air-gap, and receiving current from a battery and from a generator, each of said currents when acting alone tending to establish fluxes throughout said circuit in opposite directions, but the resultant effort causing diversion of the magnetic fluxes at the air-gap.

9. A circuit containing a generator and storage battery, and an electromagnetic switch having a permanent air-gap, a coil in shunt to the generator, and a coil in series with the generator, and a coil in shunt to the battery establishing a single flux in the switch when all the coils are active, and tending to set up independent fluxes in different limbs of the magnetic circuit when the coil in series with the generator is inactive.

10. A switch having a magnetic circuit comprising two members with an air-gap between them, one member having its flux established by a winding in shunt to the generator, the other member having a winding deriving current from a battery and a winding in series with the generator.

11. A system of electrical distribution embodying a line-switch comprising in its structure a coil in shunt to the generator-mains, a coil deriving current from the battery, the said coils opposing each other and tending to initiate a plurality of fluxes on opposite sides of the air-gap of the magnetic circuit and a coil in series with the generator.

12. An electromagnetic switch comprising a magnetic circuit including two limbs separated by a permanent air-gap, a coil establishing a flux through one limb on one side of the air-gap, an opposing coil establishing a flux through the other limb on the opposite side of the air-gap, and a coil opposing one of the said coils and tending to set up a single flux in the magnetic circuit.

13. The combination in a switch of two members of high permeability with a permanent air-gap, one fixed and the other movable, one member being surrounded with a coil in shunt to the generator, and the other member being surrounded with a coil in series with the generator and a coil in shunt to the battery.

14. A line-switch embodying fixed and movable parts separated by a permanent air-gap, a coil in shunt to a generator, and a coil receiving

current from a battery, the said coils tending to set up independent fluxes in the switch, and diverging at the air-gap, one of the said coils tending to polarize the movable part.

15. A line-switch embodying fixed and movable parts separated by a permanent air-gap, polarizing-coils therefor, the said coils tending to set up independent fluxes, and an opposing coil for one of the said coils, whereby when two of the coils are in action, a plurality of fluxes will be established, and when all three of the coils are in action they will jointly tend to establish a single flux.

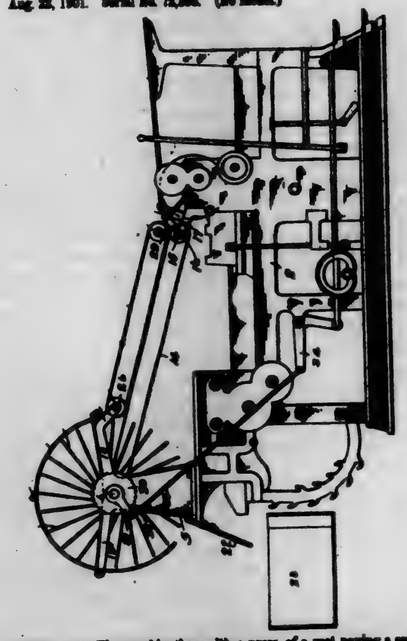
707,764. EXPANSIBLE STOPPER. REINALD L. S. DOERRY, East Orange, N. J., assignor to Standard Varnish Works, New York, N. Y., a Corporation of New York. Filed Apr. 3, 1902. Serial No. 101,870. (No model.)

Claim.—1. An expansible stopper comprising a plug having a circumferential groove around its top, an elastic ring seated in said groove and projecting above the top of the plug in tapered form, a pressure-plate engaging the ring and a handle-screw passing through the pressure-plate and engaging the plug for drawing the plate and plug together to expand the ring, substantially as set forth.

2. An expansible stopper comprising a plug, an elastic ring having its lower portion stretched around the top of the plug and its upper portion brought into tapered form by the stretching of the ring over the plug, a pressure-plate engaging the upper edge of the ring, and a handle-screw passing through the pressure-plate and engaging the plug for drawing the plate and plug together to expand the ring, substantially as set forth.

3. An expansible stopper comprising a plug, a pressure-plate, an interposed elastic ring, a screw for drawing the plate and plug together to expand the ring, the said plate having a depending annular flange engaging the ring, and an uprising annular flange engaging the handle of the said screw, substantially as set forth.

707,765. DRIER. DAVID W. BLAKE, Minneapolis, Minn. Filed Aug. 23, 1901. Serial No. 73,093. (No model.)



Claim.—1. The combination, with a press, of a reel having a series of fingers, means for revolving said reel step by step, carrier-belts extending between the fingers for automatically conveying the printed sheets therein where they are picked up by said fingers, one row being appropriated for each sheet, substantially as described.

2. The combination, with a press, of a reel having a series of fingers, means extending between the fingers for revolving said reel step by step, means for automatically conveying the printed sheets therein to be picked up one at a time by the moving fingers, one row being appropriated for each sheet, and means for preventing the premature discharge of the sheets from said reel.

3. The combination with a press, of a reel having hollow fingers, means for revolving said reel step by step, means for delivering the printed sheets to said fingers, one row of fingers being appropriated for each sheet, means for delivering hot air to said hollow fingers, and means for holding the sheets thereon, substantially as described.

4. The combination with a press, of a reel comprising a shaft, provided with a series of hubs arranged at intervals thereon and having fingers substantially tangential with respect to their hubs and said shaft, means for revolving said reel step by step, feed-belts extending between said hubs, the upper sections of said belts at their points of delivery being substantially parallel with the adjacent horizontal row of fingers, substantially as described and for the purpose specified.

5. The combination with a press, of a reel having a series of fingers, means for revolving said reel step by step, carrier-belts extending between the vertical rows of fingers and wherefrom the sheets are picked up one at a time by said fingers as the reel revolves, guide-belts provided above said carrier-belts, and means for preventing the premature discharge of the sheets from said reel, substantially as described.

6. The combination with a press, of a reel having a hollow shaft and hollow fingers communicating therewith and provided with perforations, means for delivering hot air to said shaft, means for slowly revolving said reel, means for delivering the printed sheets to said fingers, one row being appropriated for each sheet, and a suitable guard inclosing the upper portion of said reel and having a discharge-opening for the sheets in its lower side, substantially as described.

7. The combination with a press, of a reel mounted thereon and comprising a shaft provided with a series of hubs arranged at intervals and having a series of fingers, means for revolving said shaft step by step, pulleys provided on said shaft between said hubs and on the press-frame, and feed-belts connecting the opposite pulleys, substantially as described.

8. The combination with a press, of a reel mounted thereon and comprising a shaft provided with a series of hubs arranged at intervals and having a series of fingers, means for revolving said shaft step by step, pulleys provided on said shaft between said hubs and on the press-frame, feed-belts connecting the opposite pulleys, and guiding-belts provided above said feed-belts, substantially as described.

9. The combination with a press, of a shaft mounted thereon, means for revolving said shaft step by step, hubs secured on said shaft, a series of fingers for each hub, a guard extending above said fingers and having a discharge-opening in its lower side, pulleys adjustably arranged on said shaft between said hubs, corresponding pulleys provided on the press-frame, and feed-belts connecting the opposite pulleys and adapted to carry the printed sheets from the press in between the horizontal rows of fingers to be gathered up thereby, substantially as described.

10. The combination, with a press, of a revolving paper-drier having a series of paper-supports, moving carriers projecting into the space between the fingers for automatically conveying the freshly-printed sheets thereon to be lifted up thereby, one row being appropriated for each sheet and each sheet being out of contact with the other sheets.

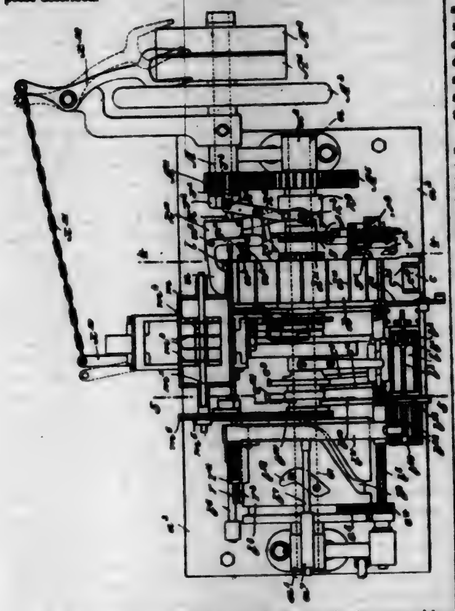
11. The combination, with a press, of a revolving drier having a series of paper-supports, means extending into the space between said supports for conveying the freshly-printed sheets thereon to be picked up as said supports pass said means, each sheet being kept out of contact with the others, and means for preventing the premature discharge of the sheets from said supports.

707,766. CIGARETTE-MACHINE. GUIO FERRARI, Philadelphia, Pa. Filed Mar. 31, 1902. Serial No. 99,341. (No model.)

Claim.—1. In a cigarette-machine, a paper-feeding mechanism, comprising a table over which the paper is adapted to travel, a block, an arm, means for holding said block in frictional contact with said arm, means for reciprocating said arm and block in a horizontal plane on and above said table, and means for limiting the reciprocatory movement of said block, substantially as and for the purposes described.

2. In a cigarette-machine, a paper-feeding mechanism, comprising a block, an arm controlling said block, means for raising and lowering said arm, means for reciprocating the arm and block in a horizontal plane, and means for holding the block in frictional engagement with said arm, substantially as and for the purposes described.

3. In a cigarette-machine, a paper-feeding mechanism, comprising a table over which the paper is adapted to travel, a frame secured to said table, a block arranged within the frame, an arm adapted to raise and lower and to reciprocate said block in a horizontal plane within said frame, said frame being adapted to limit the reciprocatory movement of said block and to shift the same on said arm, substantially as and for the purposes described.



4. In a cigarette-machine, a paper-feeding mechanism, comprising a table over which the paper is adapted to be fed, a frame secured to said table, a block, an arm adapted to raise and lower and to reciprocate said block in a horizontal plane within said frame, and adjustable means carried by said frame and adapted to limit and regulate the forward movement of said block in said frame, substantially as and for the purposes described.

5. In a cigarette-machine, a paper-feeding mechanism, comprising a block, an arm adapted to raise and lower and to reciprocate said block, a bar carried by said block adjacent to said arm, a spring resting on said bar, and a screw adjustable in said block, said screw being adapted to regulate the frictional contact of said bar with said arm and to allow the shifting of said block on said arm, substantially as and for the purposes described.

6. In a cigarette-machine, a paper-feeding mechanism, comprising a block, an arm having notches and adapted to raise and lower and to reciprocate said block, a bar carried by said block having projections at either end and resting on said arm, a spring adapted to depress said bar into engagement with said arm, an adjusting-screw adapted to engage said spring, a table, and a frame secured to said table and within which said block is adapted to reciprocate, said frame constituting a means for shifting said block on said arm so as to bring one of the projections of said bar into engagement with one of the notches of said arm at the backward movement of said block and to disengage the same at the completion of the forward movement of said block, substantially as and for the purposes described.

7. In a cigarette-machine, a paper-feeding mechanism, comprising a table over which the paper is adapted to travel, a block, an arm adapted to raise and lower said block and to reciprocate the same in a horizontal plane to thereby bring at intervals said block into and out of engagement with the paper and to shift the paper in one direction only, a frame within which said block travels and beneath which the paper is fed, and adjusting-screws located in the frame and adapted to limit the reciprocatory movement of said block and to vary the travel of said block to feed the paper forward for varying lengths, substantially as and for the purposes described.

8. In a cigarette-machine in combination with a tube-holder and tube-forming mechanism, a paper-feeding mechanism, comprising a table, a second table arranged adjacent thereto and over both of which tables the paper is adapted to travel, a block adapted to feed the paper forward from one table to the other, a latch adapted to oscillate between said tables and to cover the paper thereon, and means adapted to shift the covered portion of said paper transversely over the second table into said tube-holder and into engagement with said tube-forming mechanism, substantially as and for the purposes described.

9. In a cigarette-machine, a tube-holder, comprising a disk carrying a projecting rim or annulus, openings or mobile arranged in said annulus, said mobile being slotted through the periphery of the annulus, a ring secured to said disk, a continuously-rotating power-shaft upon which the disk is loosely supported, means controlled by said power-shaft to engage said ring and to transmit to the same and the disk an intermittent motion and to lock the ring and disk after each intermittent movement, substantially as and for the purposes described.

10. In a cigarette-machine, a tube-holder, comprising a disk having a laterally-projecting rim or annulus, mobile arranged in said rim and provided with slots traversing the annulus, a ring secured to said disk and having alternate notches and curved portions, a continuously-rotating power-shaft loosely supporting said tube-holder, and means controlled by said shaft adapted alternately to engage said notches and curved portions to impart to the ring and tube-holder an intermittent motion and to lock the same after each consecutive movement, substantially as and for the purposes described.

11. In a cigarette-machine, a tube holder or carrier, comprising a disk and a projecting rim or annulus integral therewith, slotted mobile formed in said rim or annulus, a ring carried by said disk and having alternate notched and curved portions at its inner edge, said curved portions being of a radius less than the radius of said disk, a wheel having a tooth adapted to engage the notches and having its periphery intermittently in engagement with the curved portions of said ring, substantially as and for the purposes described.

12. In a cigarette-machine, a tube holder or carrier, comprising a disk carrying an annulus in which the slotted mobile are formed, a continuously-rotating power-shaft upon which said disk and annulus are loosely supported, a ring carried by said disk and having notches in its interior periphery and curved portions between said notches, a single-toothed wheel of a radius corresponding to the radius of the curved portions of said ring, a gear-wheel adapted to travel with said single-toothed wheel, a shaft carrying both of said wheels and a gear-wheel secured to said power-shaft and meshing with the gear-wheel secured to said single-toothed wheel so as to transmit the motion of the power-shaft to said single-toothed wheel and to cause the same to engage with its teeth the notches of said ring and to change the rotary movement of said power-shaft into an intermittent movement of the tube-holder, substantially as and for the purposes described.

13. In a cigarette-machine, a tube holder or carrier comprising a disk and a projecting rim or annulus in which the slotted mobile are formed, a ring having alternate notched and curved portions and secured to said disk, a continuously-rotating power-shaft upon which the tube-holder is loosely supported, a shaft arranged below said power-shaft, a single-toothed wheel carried by said shaft and alternately engaging with its teeth the notches and with its periphery the curved portions of said ring, gear-wheels connecting the power-shaft and toothed-wheel shaft so as to transmit the rotary movement of said power-shaft to said single-toothed wheel and to impart through the same to the ring and tube-holder a step-by-step movement and to lock the same and the tube-holder against movement, substantially as and for the purposes described.

14. In a cigarette-machine, a mechanism for tucking in the end of a paper tube, comprising a wedge and a latch, means for imparting to said wedge a lateral and forward movement independent of the latch and means adapted to reciprocate said latch and oscillate the same independently of the wedge, substantially as and for the purposes described.

15. In a cigarette-machine, a tucking mechanism, comprising a wedge, a plate supporting said wedge and means adapted to move said plate and wedge both laterally and forwardly, substantially as and for the purposes described.

16. In a cigarette-machine, a tucking mechanism, comprising a wedge, a plate supporting said wedge and having an oblique slot, a horizontally-reciprocating slide adapted to engage the oblique slot of said plate and to impart to said plate and wedge reciprocatory and lateral movements in succession, substantially as and for the purposes described.

17. In a cigarette-machine, a tucking mechanism, comprising a wedge, a plate supporting said wedge having an oblique slot and angular-shaped slots arranged therein, a horizontally-reciprocating slide adapted to engage said oblique slot, a standard, bolts carried by said standard adapted to engage said angular slots, said angular slots being arranged so that when a reciprocatory movement is imparted to said plate by said slide the plate and wedge are first moved laterally and then forward, substantially as and for the purposes described.

18. In a cigarette-machine, a tube shifting and clamping mechanism, comprising a rod adapted to engage the tube at one end, an arm carried by said rod adapted to engage the paper tube at the opposite end,

and means adapted to reciprocate said rod, arm and tube, substantially as and for the purposes described.

19. In a cigarette-machine, a tube shifting and clamping mechanism comprising a rod adapted to engage the tube at one end, an arm adapted to engage the tube at the other end, a ferrule, a spring normally tending to shift said rod, arm and tube until the tube and arm are in engagement with said ferrule, and means adapted to retract said rod and arm and to bring said paper tube out of engagement with said ferrule, substantially as and for the purposes described.

20. In a cigarette-machine, a tube shifting and clamping mechanism, comprising a rod having an arm, said rod and arm adapted to engage a tube at opposite ends, a housing within which said rod and arm are adapted to reciprocate, and a clamp carried by said housing and adapted to be controlled by said arm so as to engage said tube, substantially as and for the purposes described.

21. In a cigarette-machine, a combined tube shifting and clamping mechanism, comprising a rod carrying an arm, said rod and arm adapted to engage a tube at opposite ends, a housing within which said rod and arm are adapted to slide, a clamp carried by said housing, means adapted to normally hold said clamp out of engagement with said tube, and means adapted to bring said clamp into engagement with said tube, substantially as and for the purposes described.

22. In a cigarette-machine, a combined tube shifting and clamping mechanism, comprising a rod and an arm adapted to engage a tube at opposite ends, a tube-holder, a housing within which said rod and arm are adapted to slide, a clamp carried by said housing and having an engagement with said arm, a spring normally tending to hold said clamp out of engagement with the paper tube in said tube-holder, a ferrule, a spring adapted to shift the arm and tube into engagement with the ferrule, and means adapted to retract said rod and arm to thereby disengage said tube from said ferrule and bring said arm into engagement with said clamp and to move the clamp into engagement with said tube, whereby the tube is held against displacement in said tube-holder, substantially as and for the purposes described.

23. In a cigarette-machine, a clamping mechanism, comprising two pivoted arms each having a jaw, a ferrule, means normally tending to close said jaws to bring the same into engagement with said ferrule, and means adapted to open said jaws and to disengage the same from said ferrule, substantially as and for the purposes described.

24. In a cigarette-machine, a clamping mechanism, comprising two arms each provided with a jaw and an indentation or groove, a ferrule adapted to receive the end of a paper tube, a spring normally tending to move the arms toward each other to bring the jaws into engagement with the paper tube so as to clamp said tube to said ferrule, a bolt normally tending in conjunction with the indentations or grooves to open said arms and to disengage the same from the ferrule and tube, and means adapted to alternately bring said bolt into and out of engagement with said indentations or grooves, substantially as and for the purposes described.

25. In a cigarette-machine, a combined tobacco feeding and compressing mechanism, comprising a chamber, a block forming one side of the chamber and having an obliquely-projecting rib, a slide arranged in said chamber opposite said block, a hopper adapted to contain tobacco located above said block and slide, an outlet-opening arranged in said hopper adapted to feed the tobacco partially to said projecting rib and in part directly to the chamber, and means controlled by the power-shaft of the machine adapted to reciprocate said block and slide within said chamber, substantially as and for the purposes described.

26. In a cigarette-machine, a combined tobacco feeding and compressing mechanism, comprising a chamber, a block at one side of the chamber having an obliquely-projecting rib, a slide arranged opposite said block in said chamber, a groove arranged in the bottom of said chamber, a hopper adapted to contain tobacco and located above said block and slide, an outlet-opening arranged in said hopper adapted to feed tobacco in part directly to said chamber and partially on the projecting rib, said rib being adapted to guide the greater quantity of tobacco toward the front of said chamber, substantially as and for the purposes described.

27. In a cigarette-machine, a combined tobacco feeding and compressing mechanism, comprising a block having a projecting rib located in a chamber, a slide arranged opposite said block in said chamber and having a groove, a groove arranged in the bottom of said chamber below said slide, a hopper adapted to contain tobacco and to feed the same to said chamber and to said rib, said block being adapted to shift said tobacco in said chamber toward and into said groove, and said slide adapted to compress the tobacco shifted into said groove, substantially as and for the purposes described.

28. In a cigarette-machine, a combined tobacco feeding and compressing mechanism, comprising a block having a projecting rib located in a chamber, a slide arranged in said chamber having a groove, a groove arranged in the bottom of said chamber opposite said slide, a hopper located above the chamber and adapted to feed tobacco to the same, means adapted to reciprocate said block and slide within said chamber to shift the tobacco into said groove and to compress the same therein, and means adapted to regulate the degree of compression imparted to the tobacco in said groove, substantially as and for the purposes described.

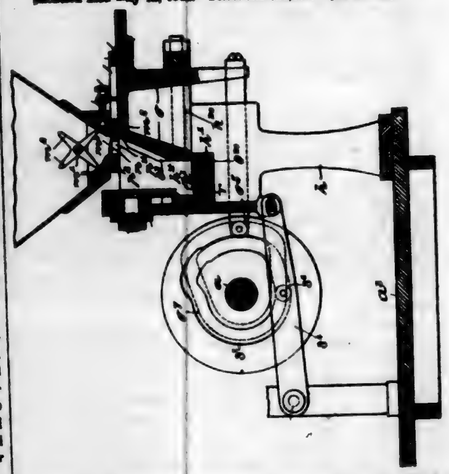
29. In a cigarette-machine, a combined tobacco-compressing mechanism, comprising a tobacco feeding and compressing chamber, a slide arranged within said chamber, a second slide arranged outside of said chamber and adapted to actuate said first slide, and means adapted to clamp the same together and to adjust their position with respect to each other, substantially as and for the purposes described.

30. In a cigarette-machine, a combined tobacco-compressing mechanism, comprising a slide located in a chamber and adapted to compress tobacco fed thereto, an opening arranged in said compressing-slide, a bolt engaging the opening in said compressing-slide, a slide adapted to actuate said compression-slide having an elongated opening, a bushing engaging said elongated opening in said actuating-slide and having an eccentrically-arranged opening through which said bolt passes, said bushing adapted when turned in the elongated opening to adjust said bolt and said compression-slide in a vertical plane with respect to the actuating-slide to regulate the degree of compression imparted to the tobacco by said compression-slide, substantially as and for the purposes described.

31. In a cigarette-machine, a combined tobacco-ejecting mechanism, comprising a plunger-rod, a chamber, a compression-slide adapted to hold tobacco under compression therein, in combination with a ferrule registering with the compressed tobacco in said chamber, a holder adapted to present a tube to said ferrule, arms adapted to clamp the end of said tube to said ferrule, and means adapted to impart to said plunger-rod, a reciprocatory and step-by-step movement to eject said tobacco from said chamber into said paper tube, substantially as and for the purposes described.

32. In a cigarette-machine, a combined tobacco-ejecting mechanism, comprising a plunger-rod, a chamber, a compression-slide adapted to hold the tobacco under compression therein in a position in alinement with the plunger-rod, in combination with a ferrule carried by the housing of said chamber and arranged in alinement with said tobacco, a tube-holder adapted to present a paper tube to said ferrule, arms adapted to clamp the end of the paper tube to said ferrule, a bail, loosely supporting said plunger-rod, a bracket carried by said bail, having a slide to which said plunger-rod is fastened, a drum adapted to impart to said bail and plunger-rod a forward movement and an auxiliary cam secured to said drum adapted to impart to said slide and plunger-rod a movement at the completion of the forward movement of the plunger-rod by said drum, substantially as and for the purposes described.

707,767. TOBACCO-MEASURING MECHANISM FOR CIGARETTE-MACHINES. Guzzo Ferrari, Philadelphia, Pa. Original application filed Mar. 21, 1902, Serial No. 99,341. Divided and this application filed May 12, 1902. Serial No. 106,967. (No model.)



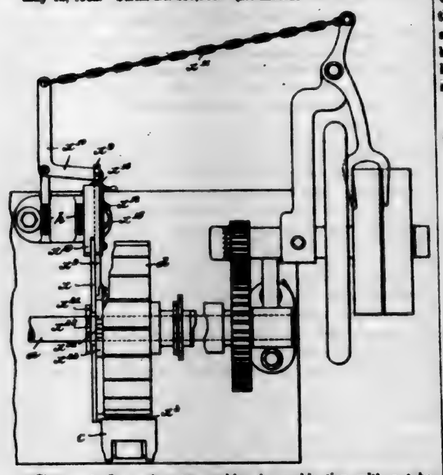
Claim.—1. In a cigarette-machine, a combined tobacco agitating feeding and measuring mechanism having a hopper, in combination with a knife normally closing an opening arranged in the hopper of said mechanism, a frame provided with a chamber arranged below said knife and adapted to receive the tobacco fed from the hopper and measure the same, a block arranged below said frame and forming in conjunction with said frame the measuring-chamber, and means adapted to reciprocate said block and knife, substantially as and for the purposes described.

2. In a cigarette-machine, a combined tobacco agitating feeding and measuring mechanism, comprising a hopper adapted to contain the tobacco, a continuously-rotating shaft arranged in the hopper, arms or wings secured to the shaft adapted to loosen and to break up the tobacco in said hopper, an outlet-opening arranged in said hopper, a knife adapted to normally close said opening, a reciprocating slide to which said knife is fixed, a frame secured to an extension of said hopper and having a bar arranged below said knife, said extension, frame and bar forming a tobacco-measuring chamber, and means adapted to shift said frame and bar with respect to the extension of said hopper to increase or decrease the size of said chamber and to thereby regulate the quantity of tobacco received therein, substantially as and for the purposes described.

3. In a cigarette-machine, a combined tobacco agitating, feeding and measuring mechanism, comprising a hopper adapted to contain the tobacco, an outlet-opening arranged in said hopper, means located in said hopper adapted to loosen the tobacco and to feed the same to said outlet-opening, means located below said outlet-opening adapted to open and close the same, means located below and opposite said outlet-opening having a chamber adapted to receive the tobacco fed thereto from said hopper, means adapted to reciprocate the means for closing the outlet-opening of said hopper and means adapted to disengage said closing means from the operating means to maintain said outlet-opening closed and to cut off the tobacco fed from said hopper into the tobacco-receiving chamber, substantially as and for the purposes described.

4. In a cigarette-machine, a combined tobacco agitating, feeding and measuring mechanism, comprising a hopper adapted to contain the tobacco, a continuously-rotating shaft located in said hopper, arms or wings secured to said shaft and rotating therewith to loosen the tobacco in said hopper, an outlet-opening arranged in said hopper, a reciprocating slide having a knife adapted to open and close said opening, a frame secured to an extension of said hopper having a bar arranged below said knife, said extension, frame and bar forming a tobacco-measuring chamber, a screw engaging said frame and adapted to shift the same with respect to the extension of said hopper to thereby increase or decrease the size of said chamber and the quantity of tobacco to be received therein, a block arranged below said frame adapted to close the same at its lower end, a bar securing said block to the slide having said knife, and means adapted to reciprocate said block actuating said slide and knife to alternately open the outlet-opening of said hopper or to close the same, substantially as and for the purposes described.

707,768. AUTOMATIC STOP MECHANISM FOR CIGARETTE-MACHINES. Guzzo Ferrari, Philadelphia, Pa. Original application filed Mar. 21, 1902, Serial No. 99,341. Divided and this application filed May 12, 1902. Serial No. 106,968. (No model.)



Claim.—1. In a cigarette-machine, in combination with a tube-holder, an automatic stop mechanism, comprising a lever having a knife, means normally tending to elevate said lever and knife, means controlled by the power-shaft for alternately depressing and freeing said lever to permit of a raising of the same, said knife being arranged to be arrested in its upward movement by paper fed to said tube-holder, means connected with said lever and a bolt-shifter, and means operated by the power-shaft adapted to actuate said means and bolt-shifter, when said lever and knife are not arrested by the paper, substantially as and for the purposes described.

2. In a cigarette-machine, in combination with a tube-holder, an automatic stop mechanism, comprising a lever carrying a knife, means normally tending to elevate said lever and knife, means actuated by the power-shaft, said means adapted to arrest the knife in its upward movement when paper is fed to said tube-holder, means connected with said lever and a bolt-shifter adapted to be raised by said lever, means operated by the power-shaft adapted to engage said means raised by said lever and to shift the same and the bolt-shifter, when said knife is not interrupted in its upward movement by said paper, substantially as and for the purposes described.

3. In a cigarette-machine, in combination with a tube-holder, an automatic stop mechanism, comprising a lever carrying a knife, means normally tending to elevate said lever and knife, means arranged on said power-shaft, which during a certain period of its rotation is adapted to arrest the upward movement of said lever and knife, means connected with a bolt-shifter and said lever and operated by said lever, means controlled by the power-shaft adapted to engage said means controlled by said lever and to shift the same and the bolt-shifter, when said lever is not arrested in its upward movement by paper normally fed to said tube-holder, and means adapted to lock the bolt-shifting means in its operative position, substantially as and for the purposes described.

4. In a cigarette-machine, in combination with a tube-holder, an automatic stop mechanism, comprising a lever having a knife, a spring normally tending to elevate said lever, a cam arranged on the power-shaft adapted to alternately depress said lever and to permit of the raising of the same by said spring, said knife being arranged to be arrested by paper fed to said tube-holder, a pawl in engagement with said lever, a disk arranged on said shaft having teeth, a slide connected with said pawl, a bell-crank lever connected with said slide, a bolt-shifter, a chain connecting said bolt-shifter with said bell-crank lever, said lever being adapted to raise the pawl of said slide and to bring the same into engagement with the teeth of said disk when not arrested in its upward movement by said paper, substantially as and for the purposes described.

5. In a cigarette-machine, in combination with a tube-holder, an automatic stop mechanism, comprising a lever having a knife, a spring normally tending to elevate said lever, a cam controlled by the power-shaft and adapted to alternately depress said lever and to permit of the raising of the same by said spring, a pawl connected with said lever, a slide connected with said pawl, a bell-crank lever connected with said slide, a bolt-shifter, a chain connecting said bolt-shifter and bell-crank lever, a latch normally held out of engagement with said slide, and a disk controlled by said power-shaft, said lever and knife adapted to be arrested in their upward movement by paper fed to said tube-holder, and when said paper is not in position to allow of the upward movement thereof to bring said pawl into engagement with the teeth of said disk and to impart to said pawl and slide a forward movement to operate said bolt-shifter and to bring said latch into engagement with said slide to lock the same and the bolt-shifter in operative position, substantially as and for the purposes described.

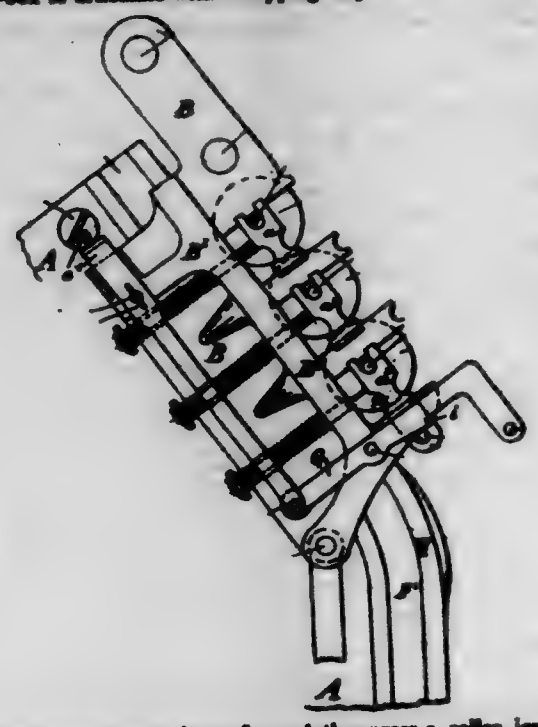
707,769. CLUTCH MECHANISM. Guzzo Ferrari, Philadelphia, Pa. Filed May 12, 1902. Serial No. 106,969. (No model.)

Claim.—In a clutch mechanism, a driven shaft provided with an internal chamber and slot, a pin or bolt extending through said shaft, a ratcheted sleeve mounted on said shaft, a pin or bolt arranged in said sleeve and passing through the slot of said shaft, a ratcheted gear-wheel loosely mounted on said shaft, and a spring mounted in the chamber of said shaft, the respective ends of which are connected with the pins of said shaft and sleeve, substantially as and for the purposes described.

707,770. PRINTING-PRESS. Herbert Gally, Brooklyn, N. Y. Filed Apr. 16, 1902. Serial No. 103,022. (No model.)

Claim.—1. In the form-roller carriage of a printing-press, a roller journal-box; having a catch-pin forming a part thereof, and projecting from its side; a lever-latch crossing the side face of the box to articulate

with the catch-pin; one arm of the lever-latch extending beyond the front of the journal-box to articulate with a tripping-step.



2. In the form-roller carriage of a printing-press a roller journal-box; a depression in the box, forming a finger-socket for moving the box by hand; a tripping device formed of a lever-latch and catch-pin; and an extension of the journal-box reaching below the box proper as a base for the catch-pin, to prevent the lever-latch from obstructing the finger-socket.

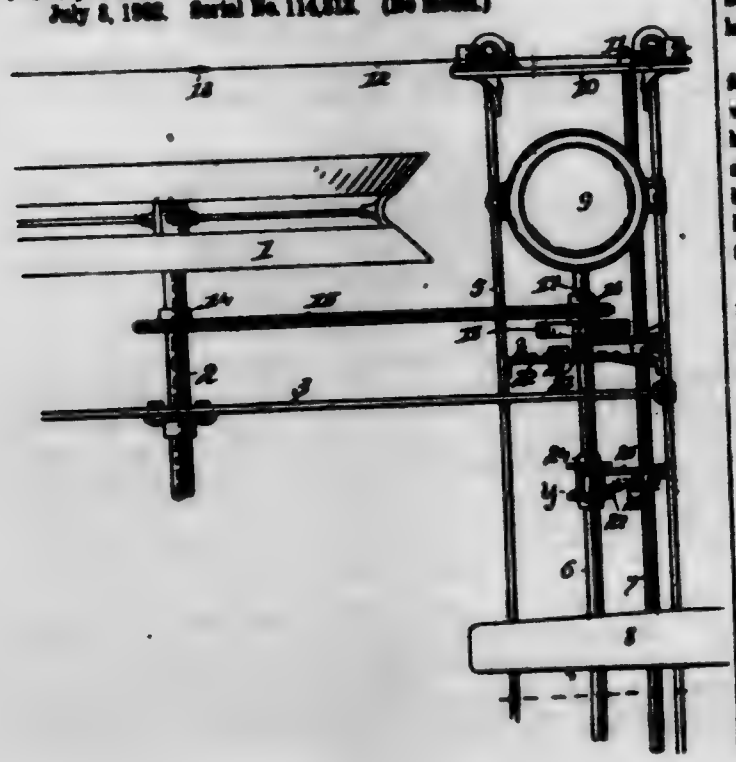
3. In a form-roller trip; a journal-box with latch-pin; a lever-latch, and an operating-bar movably attached thereto; the bar provided with a spring-tension device, and an opposing stop; the spring device for securing connection of the latch with its latch-pin, and the opposing stop for releasing the latch from the pin.

4. In a form-roller-tripping device for printing-presses; the combination with the roller journal-box and lever-latch; of the holding-catch; and the operating-bar with spring, connected to the lever-latch, to keep the latch in engagement with its holding-catch during the time the roller is prevented from inking the form.

5. In a form-roller-tripping device for printing-presses the combination of the roller journal-box; the lever-latch; the operating-bar movably attached to the lever-latch; the tripping-stop for giving motion to the operating-bar in one direction; and the spring for producing the return movement of the bar.

6. In a form-roller-tripping device for printing-presses; the combination with the lever-latch, of the operating-bar; the socket-spring, the follower, and means for adjusting the tension of the spring.

707,771. CURE-PLASTER. Levi P. Graham, Decatur, Ill. Filed July 8, 1902. Serial No. 114,512. (No model.)



Claim.—1. In a plaster, the combination of a covering-wheel, a rotating drill-shaft, a rocking check-row shaft, a wheel journaled on the drill-shaft, means for transmitting motion from the covering-wheel to the wheel on the drill-shaft, means for rocking the check-row shaft backward, means actuated by the wheel on the drill-shaft for rocking the check-row shaft forward, and means for converting the rocking motion of the check-row shaft into intermittent rotary motion in the drill-shaft.

2. In a plaster, the combination of a covering-wheel, a rotating drill-shaft, a rocking check-row shaft, a wheel journaled on the drill-shaft means for transmitting motion from the covering-wheel to the wheel on the drill-shaft, means for rocking the check-row shaft backward, means actuated by the wheel on the drill-shaft for rocking the check-row shaft forward, means for converting the rocking motion of the check-row shaft into intermittent rotary motion in the drill-shaft, an arm on the check-row shaft and a spring exerting stored force lengthwise of the arm while the check-row shaft is rocked forward.

707,772. FOLDING BABY-CARRIAGE. Annie S. Green, Brooklyn, N. Y. Filed Dec. 12, 1901. Serial No. 86,267. (No model.)

Claim.—1. In a folding baby-carriage, the combination with a body capable of folding longitudinally and laterally, of axles formed of jointed sections, embodying body portions and side portions at right angles to the body portions which side portions overlap at the central joints of the axles when the axles are in operative position and prevent further movement.

2. In a folding baby-carriage, a combination with a body capable of folding longitudinally and laterally and of running-gear connected therewith and comprising side bars, of axles formed of jointed sections embodying body portions and side portions at right angles to the body portions which side portions are turned back at their outer ends and bear against the side bars when the axles are in operative position.

3. In a folding baby-carriage, the combination with a body capable of folding longitudinally and laterally and of running-gear connected therewith and comprising side bars, of axles formed of jointed sections embodying body portions and side portions at right angles to the body portions which side portions are turned back at their outer ends and bear against the side bars when the axles are in operative position and at their inner ends overlap each other.

4. In a folding baby-carriage, the combination with a body capable of folding longitudinally and laterally and of running-gear connected therewith and comprising side bars, of axles formed of jointed sections embodying body portions and side portions at right angles to the body portions which side portions are turned back at their outer ends and bear against the side bars when the axles are in operative position and at their inner ends overlap each other, and a coupling the opposite ends of which form the central joints of the axles and whereby the axles may be moved together.

5. In a baby-carriage provided with a folding body, a supporting-frame comprising side pieces connected with said body, and hinged cross-pieces pivoted at their outer ends to said side pieces and embodying a body portion and a side portion extending at right angles to said body portion and bent back at the outer end to bear against the side piece and one of said side portions overlapping the other when the cross-pieces are extended.

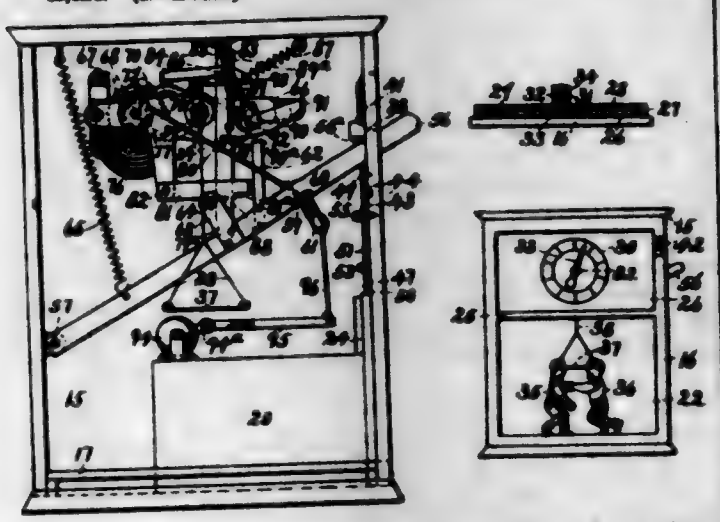
6. In a baby-carriage provided with a folding body, a supporting-frame comprising side pieces connected to said body, and hinged pivoted cross-pieces embodying a body portion and a side portion bent at one end at right angles to said body portion and the side portion of one part of said cross-pieces adapted to overlap the side portion of the other part when said cross-pieces are extended.

7. In a baby-carriage provided with a folding body, a supporting-frame comprising side pieces connected to said body, hinged pivoted cross-pieces embodying a body portion and a side portion bent at one end at right angles to said body portion and the side portion of one part of said

cross-pieces adapted to overlap the side portion of the other part when said cross-pieces are extended, and means connecting said cross-pieces.

8. In a baby-carriage provided with a folding body, a supporting-frame comprising side pieces connected to said body, cross-pieces each embodying a pair of angle-irons having their flanges at one end cut back and bent at right angles to the web which at that end is pivoted to the side pieces and at the other end the flange on one of each pair projecting and on the other of each pair cut back, and a rod pivotally connected at its opposite ends to the ends of the angle-irons having the projecting and cut-back flanges.

707,778. COIN-CONTROLLED MACHINE. PETER J. HALL and PETER S. STAUFFER, Springfield, Mass. Filed Feb. 1, 1901. Serial No. 45,620. (No model.)



Claim.—1. In combination, a dial and a spindle carrying a pointer and a roller, a spring-actuated shoe adapted to sweep over said roller and whirl said pointer, a clock-movement having an eccentric member, one or more automatons connected with said eccentric member, an operating-lever, and means dependent for action on said lever for locking, winding and releasing said clock-movement, actuating said shoe against its spring simultaneously with the locking of the clock-movement, and releasing said shoe to the action of its spring simultaneously with the releasing of the clock-movement, substantially as set forth.

2. In combination, a clock-movement provided with an eccentric member and a spool, one or more automatons connected with said eccentric member, a bell having a lever, an operating-lever, and a cord extending between said spool and bell-lever and so connected to said operating-lever as to leave a portion of said cord slack when the operating-lever is depressed, adapted to ring said bell when wound upon the spool, substantially as set forth.

3. In combination with a lever, a second lever and a detent therefor both dependent for action upon the first lever, a rocker-arm operatively connected with said second lever, a shoe on said rocker-arm, and a spindle carrying a roller and pointer, said roller being in the path of said shoe, substantially as set forth.

4. In combination, an operating-lever 56, a lever 79 a detent for said lever 79, the two latter operated by the former, a rocker-arm operatively connected with said lever 79, a spring-actuated shoe pivotally attached to said rocker-arm, a stop on the lever 79 to limit the rocking movement of said shoe in one direction, and a spindle carrying a roller and a pointer, said roller being in the path of the shoe, substantially as set forth.

5. In combination with a clock-movement as shown, a spring-actuated lever 79, a detent 81, a lock-arm pivoted to said lever and adapted to engage and release a toothed wheel of said clock-movement, and an operating-lever arranged to actuate the first lever against its spring and permit the detent to engage this lever, and to force the detent out of such engagement again, substantially as set forth.

6. In combination with a clock-movement as shown having a spool, a spring-actuated lever 79, a detent 81, a lock-arm 84 pivoted to said lever and adapted to engage and release a toothed wheel of said clock-movement, an operating-lever 56 adapted on its downward travel to engage the lower terminal of the lever 79 and actuate it against its spring and permit said detent to engage this lever, and on its upward travel to force the detent out of such engagement again, and a cord between said operating-lever and spool to wind up the clock-movement while held by said lock-arm, substantially as set forth.

7. In combination with a clock-movement as shown having a spool and an eccentric member, a spring-actuated lever 79, a detent 81, a lock-arm 84 pivoted to said lever and adapted to engage and release a toothed wheel of said clock-movement, an operating-lever 56 adapted in its downward travel to engage the lower terminal of the lever 79 and actuate it against its spring and permit said detent to engage this lever, and on its upward travel to force the detent out of such engagement again, a cord between said operating-lever and spool to wind up the clock-movement while held by said lock-arm, and one or more automatons operatively connected with the aforesaid eccentric member, substantially as set forth.

8. In combination, a spring-actuated lever and a detent therefor, a clock-movement having a spool, a lock-arm pivotally attached to said lever, an operating-lever adapted to actuate the first lever against its spring to cause said lock-arm to engage said clock-movement, and to release said first lever from said detent to release the clock-movement, a bell provided with a lever, cord connections between said spool and bell-lever, loosely attached to said operating-lever, and a weight fastened to the same below the operating-lever, whereby the clock-movement spring is wound up by the movement in one direction of the cord connections and the bell sounded by the movement in the other direction of said connections, substantially as set forth.

9. In combination, a spring-actuated lever and a detent therefor, a clock-movement having a spool and an eccentric member, a lock-arm pivotally attached to said lever, an operating-lever adapted to actuate the first lever against its spring to cause said lock-arm to engage said clock-movement, and to release said first lever from said detent to release the clock-movement, one or more automatons operatively connected with said eccentric member, a bell provided with a lever, cord connections between said spool and bell-lever, loosely attached to said operating-lever, and a weight fastened to the same below the operating-lever, whereby the clock-movement spring is wound up by the movement in one direction of the cord connections and the bell sounded by movement in the other direction of said connections, substantially as set forth.

10. The combination, of an operating-lever, a second lever and a detent therefor both dependent for action upon the first lever, a clock-movement, a rocker-arm operatively connected with and a lock-arm pivotally attached to said second lever, a shoe on said rocker-arm, a spindle carrying a roller and pointer the former being in the path of said shoe, said lock-arm adapted to engage and release said clock-movement, one or more automatons operatively connected with the latter, and a cord between said first lever and a spool on the clock-movement to wind up the spring of the same, the actuating movement of said shoe occurring simultaneously with the initial operation of the clock-movement, substantially as described.

11. The combination, of an operating-lever, a second lever and a detent therefor both dependent for action upon the first lever, a clock-movement, a rocker-arm operatively connected with and a lock-arm pivotally attached to said second lever, a shoe on said rocker-arm, a spindle carrying a roller and pointer the former being in the path of said shoe, said lock-arm adapted to engage and release said clock-movement, one or more automatons operatively connected with the latter, a bell having a lever, and a cord or cords connecting the bell-lever and a spool on the clock-movement with said first lever and weighted below the latter, the actuating movement of said shoe occurring simultaneously with the initial operation of the clock-movement and the ringing of said bell occurring at or near the end of said operation, substantially as described.

12. A lever-controlled mechanism comprising a spring-actuated lever 79 having a cam-surface 79ª at its free terminal and provided with a pivoted lock-arm 84 and stop 86 below the same, a shouldered dog 81 adapted to engage and release said lever, and an operating-lever 56 provided with a member to engage said cam-surface during the first part of the downward travel of said operating-lever, and actuate the lever 79 until locked by said dog, and to engage and force said dog out of locking engagement with the lever 79, at the end of the upward travel of the operating-lever, substantially as shown.

13. A lever-controlled mechanism comprising a spring-actuated lever 79 having a cam-surface 79ª at its free terminal and provided with a pivoted lock-arm 84 and stop 86 below the same, a shouldered dog 81 adapted to engage and release said lever, an operating-lever 56 provided with a member to engage said cam-surface during the first part of the downward travel of said operating-lever, and actuate the lever 79 until locked by said dog, and to engage and force said dog out of locking engagement with the lever 79, at the end of the upward travel of the operating-lever, and a shoe-carrying rod 89 having a downwardly-extending terminal in operative connection with the lever 79, substantially as shown.

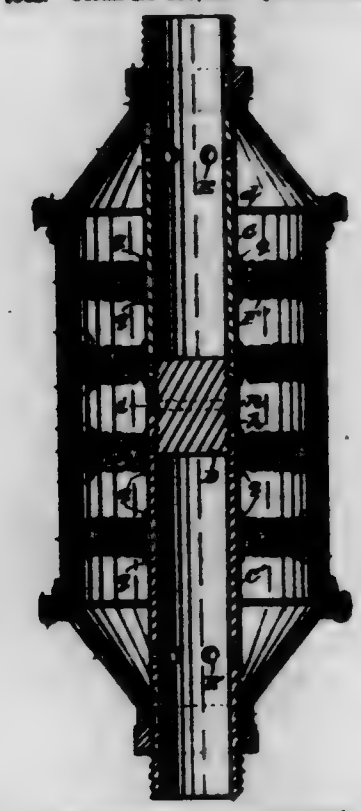
14. In combination with a clock-movement, a lever-controlled mechanism comprising a spring-actuated lever 79 having a cam-surface 79ª at its free terminal and provided with a pivoted lock-arm 84 and stop 86 below the same, a shouldered dog 81 adapted to engage and release said lever, and an operating-lever 56 provided with a member to engage said cam-surface during the first part of the downward travel of said operating-lever, and actuate the lever 79 until locked by said dog, and to engage and force said dog out of locking engagement with the lever 79, at the end of the upward travel of the operating-lever, substantially as shown.

15. In combination with a clock-movement, a lever-controlled mech-

anism comprising a spring-actuated lever 79 having a cam-surface 79ª at its free terminal and provided with a pivoted lock-arm 84 and stop 86 below the same, a shouldered dog 81 adapted to engage and release said lever, an operating-lever 56 provided with a member to engage said cam-surface during the first part of the downward travel of said operating-lever, and actuate the lever 79 until locked by said dog, and to engage and force said dog out of locking engagement with the lever 79, at the end of the upward travel of the operating-lever, and a shoe-carrying rod 89 having a downwardly-extending terminal in operative connection with the lever 79, substantially as shown.

16. A clock-spring-winding mechanism consisting of a spool on the clock-movement, an operating-lever 56, a cord fastened at one end to said spool and at the other end operatively connected with said lever, a spring-actuated lever 79 having a cam-surface 79ª at its free lower terminal and provided with a pivoted lock-arm 84 adapted to engage a toothed wheel of said clock-movement, a detent 81 for said lever 79, and a projection on said operating-lever to engage said cam-surface and actuate the lever 79 to cause the locking of the clock-movement while the descent of the operating-lever winds up the clock-spring, and to force said detent out of locking engagement with the lever 79 when the operating-lever ascends, substantially as shown.

707,774. GAS-FILTER. Barney W. Harris, Waveland, Ind. Filed May 3, 1902. Serial No. 105,726. (No model.)



Claim.—1. A gas-filter comprising an outer tube, an inner tube having perforations therein near the ends of the outer tube, a partition in the inner tube, frames attached to the inner tube, strainers supported by the frames, and caps detachably secured to the outer tube and also to the inner tube.

2. A gas-filter adapted to be connected to a pipe-line and comprising a tube having a partition therein and also perforations at either side of the partition, elongated screw-threads at the ends of the tube, strainer-frames secured to the exterior of the tube between the perforations, an outer tube extending over the strainer-frames, strainers supported by the strainer-frames, and caps having screw-threads engaging the elongated screw-threads and adapted to operate thereon and detachably secured to the ends of the outer tube, substantially as set forth.

3. In a gas-filter, the combination of the inner tubes abutting together in alinement and having the screw-threads at their ends, the plug attached to the inner ends of the tubes, the tubes having the perforations at either side of the plug, the strainer-frames secured to the exterior of the tubes between the perforations, the strainers supported by the strainer-frames, the caps attached to the outer threaded ends of said tubes, and the outer tube or casing extending about and beyond said strainers and detachably connected to said caps, substantially as set forth.

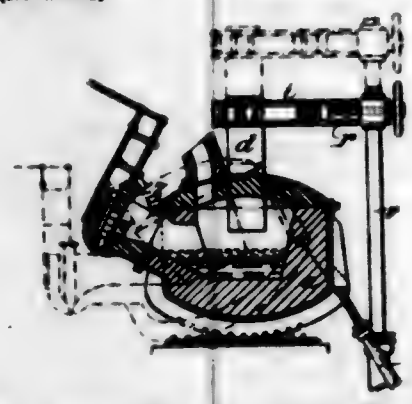
4. In a gas-filter, the combination of the outer tube having the perforated flanges at the ends thereof, the perforated inner tubes extending together through said outer tube and having the screw-threads at the ends thereof, the threads at the outer ends being elongated, the threaded plug attached to the threads at the inner ends of said inner tubes, the strainer-frames secured to said inner tubes, the strainers supported by said frames, the caps having the perforated flanges abutting with the flanges of said outer tube, the bolts securing said flanges together, the packing-washers between said flanges, and the threaded nuts secured to said caps and engaging said elongated threads on said inner tubes, substantially as set forth.

707,775. EMBALMING-CATHETER. William W. Harris, New York, N. Y., assignor to the Max Hanuke Chemical Company, New York, N. Y., a Corporation of Delaware. Filed Mar. 22, 1902. Serial No. 99,473. (No model.)

Claim.—1. In a catheter for draining and embalming purposes, the combination of a metal tube, a relatively long coiled spring normally of less diameter than the aforesaid tube and secured to the end of the same, the construction and arrangement of the parts being such that when the spring is distended a continuous passage between the tube and the aforesaid spring is formed, substantially as described.

2. In a catheter for draining and embalming purposes, the combination of a metal tube provided at its outer end with an enlargement to receive and hold any suitable coupling means, a relatively long flexible coiled spring, normally of less diameter than the aforesaid metal tube, and secured to the same, but adapted when distended to form a continuous passage with the interior of such tube, and a flexible wire extending through said tube and spring, whereby the catheter may be temporarily stiffened during its insertion, substantially as described.

707,776. OSCILLATING ELECTRIC FURNACE. Paul L. T. Héroult, La Praz, France, assignor to Société Electro Metallurgique Française, Froges, Isère, France. Filed Aug. 21, 1901. Serial No. 72,752. (No model.)



Claim.—1. In an oscillatory electric furnace, the combination of an electrode, a support, a collar or loop surrounding said electrode and holding it on said support, copper wedges pressed against said electrode by said collar, and a connection between said wedges and the electric circuit.

2. The combination with an oscillatory electric furnace, of an electrode movable relatively thereto and oscillating therewith, hydraulic means for oscillating said furnace and electrode, and hydraulic means for moving said electrode relatively to said furnace.

3. The combination with an electric furnace carrying arched cogged rails on its bottom, of similarly-cogged rails engaging said arched rails and supporting said furnace and upon which said furnace may be oscillated or tipped, an electrode movable relatively to said furnace and oscillating therewith, hydraulic means for oscillating said furnace and electrode, and hydraulic means for moving said electrode relatively to said furnace.

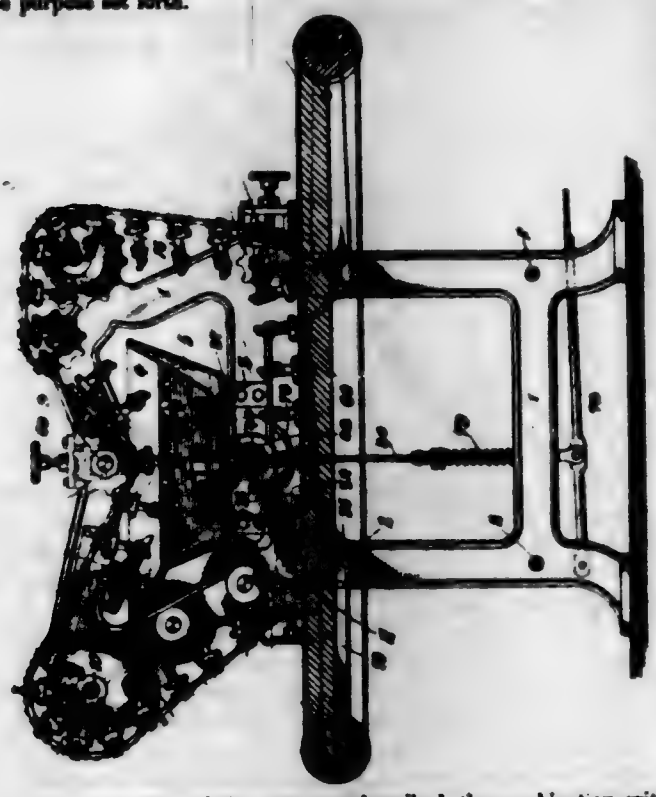
707,777. CHOCOLATE COATING OR DIPPING MACHINE. George J. Hires, New York, N. Y. Filed Dec. 14, 1899. Serial No. 740,262. (No model.)

Claim.—1. In a machine of the character described, the combination, with a receptacle for containing the coating substance, of an endless chain or carrier provided with a confection-holder, means for operating said chain or carrier with a continuous movement and guiding the same to pass the confection-holder through the coating substance in said receptacle, and means independent of the holder for retaining the confection in said holder and permitting its discharge from the latter at a certain predetermined point.

2. In a machine of the character described, the combination, with a receptacle for containing the coating substance, of an endless chain or carrier provided with a pivotally-supported holder for supporting the confection to be coated, and means for operating said chain or carrier and guiding the same to pass the confection-holder through the coating substance in said receptacle, for the purpose set forth.

3. In a machine of the character described, the combination, with

a receptacle for containing the coating substance, of an endless chain or carrier provided with a detachably-connected confection-holder, and means for operating said chain or carrier and guiding the same to pass the connected confection-holder through the coating substance in said receptacle for the purpose set forth.



4. In a machine of the character described, the combination, with a receptacle for containing the coating substance, of an endless chain or carrier provided with a confection-holder, a support for receiving the coated confections, means for operating said chain or carrier with a continuous movement and guiding the same to pass the confection-holder through the coating substance in said receptacle and then to a position adjacent to said support, and means, independent of the holder, for retaining the confections therein after being coated and subsequently permitting their discharge upon said support at a predetermined point.

5. In a machine of the character described, the combination, with a receptacle for containing the coating substance, of an endless chain or carrier provided with a confection-holder, an endless apron for receiving the coated confections, means for operating said chain or carrier with a continuous movement and guiding the same to pass the confection-holder through the coating substance in said receptacle and then to a position adjacent to said endless apron, means independent of the holder for retaining the confections therein after being coated and subsequently permitting their discharge upon said apron, and means for moving said apron with an intermittent movement, for the purpose set forth.

6. In a machine of the character described, the combination, with a receptacle for containing the coating substance, of an endless chain or carrier provided with a confection-holder, a support for receiving the coated confections, means for operating said chain or carrier and guiding the same to pass the confection-holder through the coating substance in said receptacle and then to a position above said support, and means for communicating a shaking or jarring movement to the holder for the purpose of loosening the coated confections therein.

7. In a machine of the character described, the combination, with a receptacle for containing the coating substance, of an endless chain or carrier provided with a confection-holder, a support for receiving the coated confections, means for operating said chain or carrier and guiding the same to pass the confection-holder through the coating substance and then to a position above said support, plates located adjacent to a portion of the path of movement of said holder for holding the confections therein, and a reciprocating plate or finger operating at the terminal end of said retaining-plates, for the purpose set forth.

8. In a machine of the character described, the combination, with a receptacle for containing the coating substance, of an endless chain or carrier provided with confection-holders, a support for receiving the coated confections, means for operating said chain or carrier and guiding the same to pass the confection-holders through the coating substance and to a position above said support, means for subjecting said holders to a shaking or jarring movement above the said receptacle, and means for subjecting said holders to a second shaking or jarring movement above the said support, for the purpose set forth.

9. In a machine of the character described, the combination, with a receptacle for containing the coating substance, of an endless chain or carrier provided with confection-holders, means for operating said chain or carrier and guiding the same to pass the confection-holders through the coating substance in said receptacle, and means for vertically adjusting the path of movement of the holders relative to said receptacle and regulating the slack of the chain or carrier, for the purpose set forth.

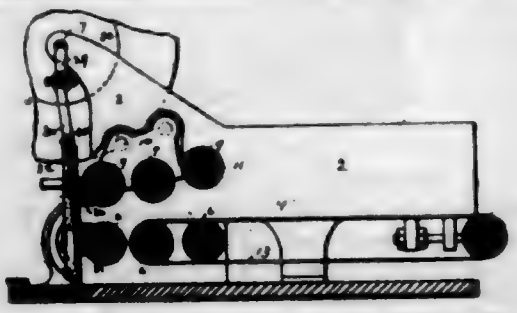
10. In a machine of the character described, the combination, with a receptacle for containing the coating substance, of two endless chains or carriers moving in a path parallel with each other, and each being provided with a series of bracket-arms, confection-holders supported by and between said bracket-arms of the opposite carriers, and means for operating said carriers and guiding the same to pass the confection-holders through the coating substance in said receptacle, for the purpose set forth.

11. In a machine of the character described, the combination, with a receptacle for containing the coating substance, of two endless chains or carriers moving in a path parallel with each other, each being provided with a series of pivotally-supported bracket-arms, confection-holders removably supported by and between said bracket-arms of the opposite carriers, a support for receiving the coated confections, and means for operating said carriers with a continuous movement and guiding the same to pass the confection-holders through the coating substance in said receptacle and then to a position to deposit the coated confections upon the said support.

12. A confection-holder, comprising a supporting-bar having two upper oppositely-sloping surfaces, and an open-sided cup located upon the upper side of said bar.

13. A confection-holder, comprising a supporting-bar having two upper oppositely-sloping surfaces, and an open-sided cup located upon the upper side of said bar, the said cup being composed of a ring and two side pieces connecting at one end with said ring and at their opposite end connected with said bar at a point distant from each other.

707,778. TOBACCO-CUTTING MACHINE. MAX HIRSCH, New York, N. Y. Filed Nov. 20, 1899. Serial No. 737,580. (No model.)



Claim.—1. The combination of a frame provided with means for containing material to be cut, and a stationary knife, with a crank-shaft, a knife-holder connected therewith, and guides having curved ways for guiding the lower end of the holder, the concave sides of said curved ways facing the stationary knife, substantially as described.

2. The combination of a frame provided with a feeding-trough having a mouth and a stationary knife, with a crank, a knife-holder connected therewith, a pair of adjustable guides provided with curved ways to which the lower end of the holder is connected, the concavity of said curved ways facing toward the mouth of the trough, substantially as described.

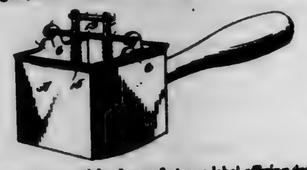
3. The combination of a main frame, a movable frame supported by the main frame, a roller carried by the movable frame, a mouthpiece 38 carried by the movable frame adjacent to said roller, a mouthpiece beneath the same carried by the main frame, a roller adjacent to said mouthpiece and opposed to the other roller, a knife-holder, means for guiding and reciprocating the same, and means for depressing the movable roller and the adjacent mouthpiece and regulating the pressure between the rollers, substantially as described.

707,779. WHIFFLETREE-HOOK. CLAUDE V. HOOVER, Chattanooga, Tenn. Filed July 10, 1902. Serial No. 115,078. (No model.)

Claim.—In a device of the character described, the combination with a loop terminating in a neck having a bearing-slot, said neck terminating in a hook, of a second hook to coact with the first-named hook, said second hook being provided with a lateral stud having a head, said

stud being seated in the slot and its head being of greater diameter than the slot, whereby, when the loop is engaged with the whiffletree, the stud will be prevented from withdrawing from the slot, substantially as set forth.

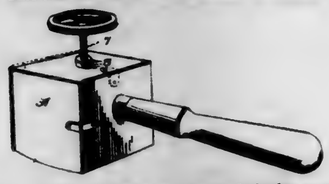
707,780. LABEL-AFFIXING DEVICE. GEORGE E. HOWARD, Washington, D. C. Filed Mar. 31, 1902. Serial No. 101,706. (No model.)



Claim.—1. As an article of manufacture a label-affixing device comprising a box or receptacle open at the bottom for the discharge of the labels, a handle extending out laterally from one side, and a spring-actuated follower adapted to slide in the box or receptacle and force forward the labels contained in the box or receptacle.

2. As an article of manufacture, a label-affixing device comprising a box or receptacle, open at the top and bottom and closed at the sides, a handle extending out laterally from one side, and a spring-actuated follower adapted to slide in the box or receptacle.

707,781. LABEL-AFFIXER. GEORGE E. HOWARD, Washington, D. C. Filed Mar. 31, 1902. Serial No. 101,707. (No model.)



Claim.—1. The combination of a receptacle having an open face for the discharge of its contents, and lips projecting inwardly from opposite sides or edges of the opening, of a follower, a screw turning in threads in the side of the receptacle opposite the open face and swiveled in the follower, a thumb-nut or wheel on the screw by which to turn it and a handle by which the entire device is moved in the operation of labeling.

2. The combination with a receptacle having an open face for the discharge of its contents, and lips projecting inwardly from opposite sides or edges of the opening, of a follower, a screw turning in threads in the side of the receptacle opposite the open face and swiveled in the follower, means whereby to turn the screw, and a handle extending in a direction parallel with the open face of the receptacle by means of which the receptacle is swung bodily in the operation of applying the label.

3. A label-affixing device consisting of a receptacle having an open face and lips projecting inwardly from opposite sides thereof, a pair of followers, a spring interposed between said followers, and a screw-feed for the outer follower and a handle extending laterally from the receptacle whereby the device is wielded in the operation of applying a label.

4. The combination with a receptacle adapted to contain labels, said receptacle having one open face, the other faces all being closed, a handle connected with the box or receptacle by which the latter is lifted and swung bodily in the operation of applying a label, a follower, a screw connected therewith and extending through a hole in one of the closed sides of the box or receptacle, and means for feeding the screw inward or outward through the hole whereby to move and control the position of the follower.

5. The combination with a receptacle adapted to contain labels, said receptacle having one open face, the other faces all being closed, a handle connected with the box or receptacle by which the latter is lifted and swung bodily in the operation of applying a label, a follower, a screw connected therewith and extending through a hole in one of the closed sides of the box or receptacle, and means for feeding the screw inward or outward through the hole whereby to move and control the position of the follower, the screw and follower permanently retained in the box or receptacle.

6. The combination with a receptacle adapted to contain labels, said receptacle having one open face, the other faces all being closed, a handle connected with the box or receptacle by which the latter is lifted and swung bodily in the operation of applying a label, a follower, a screw connected therewith and extending through a hole in one of the closed sides of the box or receptacle, and a nut through which the screw turns for feeding the screw inward or outward through the hole whereby to move and control the position of the follower.

707,782. LABEL-HOLDER. GEORGE E. HOWARD, Washington, D. C. Filed Apr. 8, 1902. Serial No. 101,982. (No model.)

Claim.—1. As an article of manufacture, a label-holder, consisting of a box having the bottom and rear disposed at an acute angle to each other, and a gravity-weight adapted to rest upon the labels, having sliding connection with the box and carrying a guard-plate in front of the outer edge of the labels.

2. As an article of manufacture, a label-holder consisting of a box having bottom, rear and sides and open at the front and top, a weight having sliding connection with the sides and a guard-plate connected with the weight and having sliding connection with the forward edge of the box.

3. As an article of manufacture, a label-holder comprising a box adapted to receive the labels, a gravity-weight adapted to rest loosely on the labels and retain them in the box, a frame connected with the weight and carrying a guard-plate which extends in front of the labels and prevents their sliding bodily from the holder.

4. As an article of manufacture, a label-holder comprising a box having sides and bottom adapted to receive the labels, a gravity-weight adapted to rest loosely on the labels and retain them in the box, and a frame connected with the weight and carrying a guard-plate which extends in front of the labels and cooperates with the sides and bottom of the box to prevent their sliding bodily from the holder.

5. As an article of manufacture, a label-holder consisting of a box open at the forward end and a gravity-weight having a sliding connection with the box and resting upon the labels held in the box, a frame connected with the weight and extending forwardly to embrace the forward edge of the uppermost labels and a guard-plate secured to this frame and extending downwardly therefrom and having sliding connection with the box, whereby the frame, weight and plate maintain a uniform relative position in their descent with respect to the box.

6. As an article of manufacture, a label-holder consisting of a box, a weight having sliding connection therewith, a frame carrying a curved or rounded lip at its outer end over which the labels are slid and a guard-plate depending from the frame and having sliding connection with the box.

7. The combination with the box of a label-holder, of a weight, frame and guard-plate connected together, having sliding connection with the box at front and rear thereof and removably connected with the box.

8. The combination with a box having slotted sides and bottom, of a weight having bearings which extend through the slotted sides of the box, a guard-plate extending through the slot in the bottom, and a frame connecting the guard-plate with the weight.

9. The combination with a box having slotted sides and bottom, of a weight having bearings which extend through the slotted sides of the box, a guard-plate extending through the slot in the bottom, a frame connecting the guard-plate with the weight and means for retaining the weight, frame and guard-plate removably in place.

10. The combination with a box having slotted sides and bottom, of a weight having bearings which extend through the slotted sides of the box, a guard-plate extending through the slot in the bottom, a frame connecting the guard-plate with the weight, and antifriction-rollers journaled on the bearings and fitted to the slots in the sides of the box.

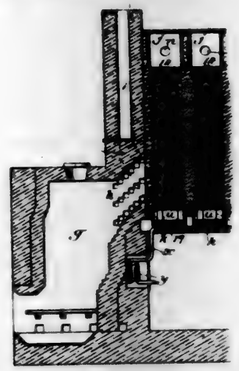
11. In a label-holder the combination with a receptacle having sides and bottom, of a keeper or guard-plate against which and the sides the edges of the labels rest, said keeper or guard-plate having sliding connection with the holder and constructed and adapted to descend automatically as the labels are withdrawn from the holder.

12. In a label-holder the combination with a receptacle having sides and bottom, of a keeper or guard-plate against which and the sides the edges of the labels rest, said keeper or guard-plate having sliding connection with the holder and constructed and adapted to descend automatically as the labels are withdrawn from the holder, and means resting on the labels in the holder for regulating and controlling the descent of the keeper or guard-plate.

13. The combination with a box adapted to receive labels, said box having an open top and front, of a keeper or guard-plate located at and having sliding connection with the forward portion of the box, and means connected therewith and resting on the labels for controlling the descent of the keeper or guard-plate.

14. The combination with a box constructed and adapted to receive labels, of a frame and a guard carried thereby beyond the outer edges of the labels, said frame supported upon the labels whereby the guard is lowered automatically by the removal of the labels.

707,788. PROCESS OF MANUFACTURING ILLUMINATING-GAS. CHARLES W. ISSELL, New York, N. Y. Filed June 13, 1901. Serial No. 64,363. (No specimens.)



Claim.—In the process of manufacturing illuminating-gas from bituminous coal, the loosening of the residual incandescent coke remaining in the generating-retort after the expulsion of said gas to the extent desired, by the introduction into said retort around the said coke of a sufficient quantity of steam to produce the decomposition or combustion and conversion into gas of that portion of said coke contiguous to the sides of the retort, substantially as herein described.

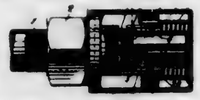
707,784. SWEAT-BAND FOR HATS. CHARLES L. JOHNSON, Woodburn, Oreg. Filed Apr. 30, 1900. Serial No. 715,042. (No model.)

Claim.—1. As an article of manufacture, a hat comprising a body portion, a stiffening-strip of non-absorbent material arranged within and in contact with the body portion, a sweat-band of perforated, resilient, non-absorbent, non-elastic material within the first strip and separated therefrom by tubular separating-strips, substantially as described.

2. The combination with a hat, of a strip of non-absorbent material secured to the inner portion thereof at the zone usually occupied by the sweat-band, a sweat-band formed of a strip of resilient, non-absorbent and non-elastic material, and a plurality of tubular perforated separating-strips secured to the said strip and to the sweat-band, the said strip constituting a stiffening-band, substantially as described.

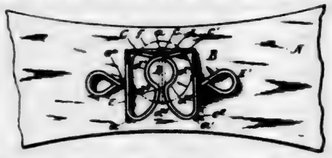
707,785. FASTENING DEVICE. PETER KLEBER, Wiesbaden, Germany. Filed Nov. 27, 1901. Serial No. 83,013. (No model.)

Claim.—1. A fastening device having two sets of bayonet-slots, one set being arranged in a central body, the other set being provided in a sleeve surrounding said central body, a corresponding set of noses provided on a ring slidingly arranged on the surrounding sleeve, each of said noses entering one slot in the surrounding sleeve and one corresponding slot in the central body, a spring arranged on the surrounding sleeve and engaging the said ring substantially as and for the purpose described.



2. A fastening device having two sets of bayonet-slots, one set being arranged in a central body, the other set being provided in a sleeve surrounding said central body, a corresponding set of noses provided on a ring slidingly arranged on the surrounding sleeve, each of said noses entering one slot in the surrounding sleeve and one corresponding slot in the central body, a spring arranged on the surrounding sleeve and engaging the said ring, a casing fixed to an outwardly-extending disk of the said surrounding sleeve substantially as and for the purpose described.

707,786. NECKTIE-FASTENER. OTTO KRAUS, New York, N. Y. Filed May 12, 1902. Serial No. 107,080. (No model.)



Claim.—1. A wire necktie-fastener comprising bracing provision having its members horizontally separated for receiving a button-head, means at one side of said provision for attachment to the shield, a pair of bent arms connected to said provision at the other side thereof and presenting a bearing-eye and contracted entrance for said bearing-eye, the latter being closed contiguous to the connection of the arms with the separated members to present a closed stop for a button-shank bearing in the eye.

2. A wire necktie-fastener comprising horizontal bracing provision having its members separated for receiving a button-head, means at one side of said provision for attachment to the shield, a pair of bent arms at the other side of said provision and presenting a bearing-eye and contracted entrance for said bearing-eye, the latter being closed contiguous to the separated members to present a closed stop for a button-shank bearing in the eye; and provision for independently bracing said arms relative to the shield.

3. A wire necktie-fastener comprising horizontal bracing provision having its members separated for receiving a button-head, and crossed at one side, means for attaching the provision to the shield, and a pair of bent arms connected to the crossed members and presenting a bearing-eye and contracted entrance for said bearing-eye, the latter being immediately contiguous to the crossed members.

4. A wire necktie-fastener comprising horizontal bracing provision having its members separated for receiving a button-head and crossed at one side, means at one side of said provision for attachment to the shield, a pair of bent arms connected to the members at the crossed side thereof and presenting a bearing-eye and contracted entrance for said bearing-eye, the bearing-eye being immediately contiguous to the crossed members; and provision for independently bracing said arms relative to the shield.

5. A wire necktie-fastener comprising a narrow contracted securing-tongue and a distended or expanded horizontal loop immediately contiguous thereto and adapted to bear against the shield for serving as a stop for the tongue, said horizontal loop forming a braced support for a pair of arms bent to present a bearing-eye and contracted entrance therefor, crossed members yieldingly contracting said entrance, and independent bracing provision for said arms relative to the shield.

6. A wire necktie-fastener comprising horizontal bracing provision having its members separated for receiving a button-head, means at one side of said provision for attachment to the shield, a pair of bent arms at the other side of said provision and presenting a bearing-eye and contracted entrance for said bearing-eye, the latter contiguous to the separated members; and laterally-extended reinforces bearing against the shield and contributing to maintain both the arms and separated bracing members in their normal positions.

7. A wire necktie-fastener comprising a narrow contracted securing-tongue and a distended or expanded horizontal loop immediately contiguous thereto and adapted to bear against the shield for serving as a stop for the tongue, said horizontal loop embodying crossed members, a pair of arms supported by said crossed members and bent to present a bearing-eye and spring-yielding contracted entrance for said bearing-eye, and

independent provision for bracing said arms relative to the shield, said bracing provision including laterally-extended reinforces for bearing against the shield.

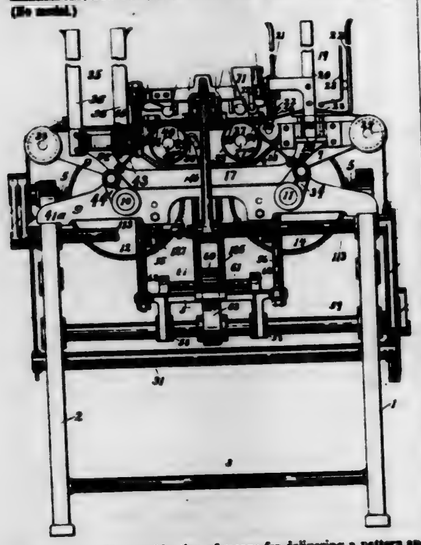
8. A wire necktie-fastener comprising a horizontal spring-loop designed to bear at one side against the shield and having at the opposite side crossed members, arms connected to said crossed members and bent to present a bearing-eye, said crossed members constituting a barrier between said eye and loop, and means for securing said parts to the shield.

9. A wire necktie-fastener comprising horizontal bracing provision having its members separated for receiving a button-head, and crossed at one side, and relatively movable with respect to each other, means for attachment to the shield, and a pair of bent arms connected to the crossed members and presenting a bearing-eye and contracted entrance for said bearing-eye, those portions of the arms at the inner side of the entrance being more abrupt than those constituting the approach thereto.

10. A wire necktie-fastener comprising a narrow contracted securing-tongue and a horizontal spring-loop designed to bear at one side against the shield and having at the opposite side crossed members relatively movable with respect to each other, arms connected to said crossed members and bent to present a bearing-eye and contracted entrance for said bearing-eye, those portions of the arms at the inner side of the entrance being more abrupt than the parts constituting the approach thereto.

11. A wire necktie-fastener comprising horizontal bracing provision having its members separated for receiving a button-head, means at one side of said provision for attachment to the shield, a pair of bent arms at the other side of said provision and presenting a bearing-eye and contracted entrance for said bearing-eye, the latter being contiguous to the separated members; and lateral reinforces bearing against the shield and having their wires twisted together at their inner connections with the rest of the fastener.

707,787. MACHINE FOR AFFIXING LABELS. WILLIAM F. HARRINGTON, New York, N. Y. Filed July 2, 1901. Serial No. 66,826. (No model.)



Claim.—1. The combination of means for delivering a pattern and a label to each other, means for causing the pattern and label to register edge to edge with each other, means for securing the folds of the pattern and the label together, and means for causing the successive operation of each of said above-named means, substantially as described.

2. The combination of separating means for separating a pattern and a label from respective supply-hoppers, means for delivering the pattern and the label to each other, means for causing the pattern and the label to register, means for attaching them together, means for securing the folds of the pattern, and means for causing the successive operation of each of said above-named means, substantially as described.

3. The combination of means for delivering a pattern and a label to each other, means for applying paste to the label, means for causing them to register, means for pressing them together, means for securing the folds of the pattern, and means for causing the successive operation of each of said above-named means, substantially as described.

4. The combination of means for separating a pattern and a label from respective supply-hoppers, means for delivering the label and pattern to each other, means for printing upon the pattern, means for pasting the label to the pattern, means for securing the folds of the pattern, and means for causing the successive operation of each of said above-named means, substantially as described.

5. The combination of separating means for separating a pattern and a label from respective supply-hoppers, means for delivering the same to each other, means for causing them to register, means for pasting the pattern and label to each other, securing means for fastening the folds of the pattern, and means for causing the successive operation of each of said above-named means, substantially as described.

6. The combination of separating means for separating a pattern and a label from respective supply-hoppers, securing means for fastening the folds of the pattern, means for pasting the label to the pattern, and means for causing the successive operation of each of said above-named means, substantially as described.

7. The combination of a securing means for fastening the folds of a pattern, means for delivering the pattern and a label to each other, means for attaching them together, and means for causing the successive operation of each of said above-named means, substantially as described.

8. The combination of a securing means for fastening the folds of a pattern, means for delivering the pattern and a label to each other, means for causing them to register, means for attaching them together, and means for causing the successive operation of each of said above-named means, substantially as described.

9. The combination of means for delivering a pattern and a label to each other, means for securing the folds of said pattern at the side thereof, means for attaching the label and the pattern together, and means for causing the successive operation of each of said above-named means, substantially as described.

10. The combination of means for delivering a pattern and a label to each other, means for securing the folds of the pattern at a side thereof, means for applying paste to the label, means for pressing the pattern and label together, and means for causing the successive operation of each of said above-named means, substantially as described.

11. The combination of means for delivering a pattern and a label to each other, of a paste-roller, means for raising a portion of the label into contact with the paste-roller on its way to the pattern, means for pressing the pattern and label together, means for securing the folds of the pattern, and means for causing the successive operation of each of said above-named means, substantially as described.

12. The combination of means for delivering a pattern and a label to each other, of a paste-roller, means for bringing the label in contact with the paste-roller on its way to the pattern, means for securing the folds of the pattern, and means for causing the successive operation of each of said above-named means, substantially as described.

13. The combination of a reciprocating carrier-strap, an open-ended hopper having a supporting-shelf for the hopper contents, means for moving said hopper so that its contents are intermittently brought into contact with the carrier-strap while moving in the direction to disengage the contents from the shelf and for maintaining the contact while moving in opposite direction to remove the disengaged contents, and means for operating said carrier-strap, substantially as described.

14. The combination of a reciprocating carrier-strap, an open-ended hopper having a supporting-shelf for the hopper contents and arranged to receive the said contents at an angle to the sides of the hopper, and means for intermittently moving the hopper to bring its contents into engagement with the strap while moving in the direction to disengage the contents from the shelf and for maintaining the contact to remove the disengaged contents, substantially as described.

15. The combination of a reciprocating strap, of an open-ended hopper having a forward shelf and a rear shelf transversely located with respect to said strap, the contents of said hopper being adapted to rest upon said shelves, and means for moving said hopper to bring its contents into engagement with the strap, substantially as described.

16. The combination of a reciprocating strap, of an open-ended hopper having a forward shelf and a rear shelf, the contents of said hopper being adapted to rest upon said shelves, and means for moving said hopper to bring its contents into engagement with the strap shortly before the strap has completed its rearward movement, and means for moving the hopper contents out of engagement with the strap when the lowermost sheet is removed from the hopper, substantially as described.

17. The combination of a hopper having an open-ended bottom and a shelf adapted to support one edge of a pile of sheets of paper when contained in said hopper, and means for moving the lowermost sheet in one direction to remove it from said shelf, and means for moving the sheet in the opposite direction to move it under said shelf and from the hopper, substantially as described.

18. The combination of a hopper having an open-ended bottom and a shelf for supporting one edge of the contained sheets of paper, a reciprocating strap or straps, and means for bringing the open-ended bottom in contact with the strap or straps while moving in one direction to disengage the lowermost sheet from said shelf and maintaining the contact when the strap moves in the opposite direction to remove the sheet from the hopper, substantially as described.

19. The combination of a hopper for patterns and a hopper for labels, means for separating the patterns and labels from their respective hoppers and for bringing them together, means for attaching the pattern and label together, and means for moving the pattern and label together to said attaching means, substantially as described.

20. The combination of a hopper for patterns and a hopper for labels, means for separating the patterns and labels from their respective hoppers and for bringing the separated pattern and label together, means for securing the folds of the pattern, means for attaching the pattern and label together, means for moving the pattern and label together to said securing and attaching means, and means for causing the successive operation of each of said above-named means, substantially as described.

21. The combination of means for delivering a pattern and a label to each other, means for causing the same to register, binder-forming mechanism and binder-clenching mechanism, means for delivering the pattern and label to said binder-clenching mechanism, and means for causing the successive operation of each of said above-named means, substantially as described.

22. The combination of means for delivering a pattern and a label to each other, means for causing the pattern and label to register, means for forming a binder at one side of said pattern and label, and means for clenching said binder around the edge of said pattern and label, substantially as described.

23. The combination of means for delivering a pattern and a label to each other, means for causing the same to register, a wire-feeding mechanism, mechanism for forming a binder of the wire from said wire-feeding mechanism, means for delivering the pattern and label to the binder-forming mechanism, a clencher-head adapted to bend the binder around the edge of the pattern and label, and means for operating said clencher-head, substantially as described.

24. The combination of means for delivering a pattern and a label to each other, means operative upon the edges of said pattern and label for causing the same to register edge to edge with each other, means for securing them together, and means for causing the successive operation of each of the above-named means, substantially as described.

25. The combination of means for delivering a pattern and a label to each other, means for causing the same to register, means for applying paste to said label, a guide-plate, means for delivering said pattern and label upon said guide-plate, a binder-forming mechanism, a clencher-head adapted to attach the binder to the pattern and label, means for operating said clencher-head, and means for causing the successive operation of each of the above-named means, substantially as described.

26. In a machine of the character described, the combination with a bed-plate, means for delivering a pattern thereto, means for clamping the pattern to the bed-plate, a clencher-head, mechanism for moving the clencher-head around the edge of said bed-plate and down upon the pattern, clencher-head-removing clamping means, substantially as described.

27. In a machine of the character described the combination with a bed-plate, of means for delivering a pattern thereto, means for clamping the pattern to the bed-plate, a clencher-head, and cam mechanism for moving said clencher-head around the edge of said bed-plate and down upon the pattern, the said clencher-head removing the said clamping means before contacting with the pattern, substantially as described.

28. In a machine of the character described the combination with a bed-plate, of means for delivering a pattern thereto, means for clamping the pattern to the bed-plate, a clencher-head, cam mechanism for moving the clencher-head around the edge of said plate and down upon the pattern, the said clencher-head removing the said clamping means before contacting with the pattern, and means for adjusting the height to which said clencher-head may travel, substantially as described.

29. In a machine of the character described the combination with a bed-plate, of means for delivering a pattern thereto, a clencher-arm carrying a clencher-head, a pivoted arm to which said clencher-arm is pivoted, and two cams operating respectively upon the ends of the clencher-arm and said second-mentioned arm, said cams acting to raise and lower said clencher-arm and to move said clencher-arm upon its pivot, substantially as described.

30. The combination of a chute, a trough, a packer-plate traveling between said chute and said trough and having an opening therein, a retainer-hook adapted to engage the end of the trough and itself projecting through said opening, and means whereby as the said packer-plate moves toward said trough the said hook will be momentarily snapped away from the end of the trough, substantially as described.

31. The combination of a chute, a trough, a packer-plate rocking between said chute and the end of said trough, a retainer-hook normally engaging the end of said trough, and means for disengaging said retainer-hook when the packer-plate rocks toward the end of the trough, substantially as described.

32. The combination of a chute, a trough, a packer-shaft carrying a packer-plate, means for rocking said shaft whereby said packer-plate is rocked between said chute and the end of the trough, a retainer-hook normally engaging the end of said trough, and a cam on said packer-shaft adapted to disengage said retainer-hook, substantially as described.

33. The combination of a slotted guide-plate, means for delivering a pattern and a label to the respective slots in said plate, a chute, and a traveler-arm adapted to move said pattern and label from said slots to said chute, substantially as described.

34. The combination of a slotted guide-plate, means for delivering a pattern and a label to the respective slots in said plate, presser mechanism, a chute, and a traveler-arm adapted to move said pattern and label from said slots to said presser mechanism and from said presser mechanism to said chute, substantially as described.

35. The combination of a slotted guide-plate, means for delivering a pattern and a label into the respective slots, means for causing them to register, presser mechanism, a chute, a traveler-arm adapted to move said pattern and label from said slots to said presser mechanism and from said presser mechanism to said chute and means for raising said guide-plate to bring the pattern and label into engagement with the traveler-arm, substantially as described.

36. The combination of a hopper open at the bottom and having a forward and a rear supporting-shelf adapted to support a pile of labels in said hopper, and means for first disengaging a label from one of said shelves, then from the other shelf, and then removing the label from the hopper, substantially as described.

37. The combination of a hopper open at the bottom and having a forward and a rear supporting-shelf adapted to support a pile of labels in said hopper, and a reciprocating strap or straps adapted to first disengage a label from one of said shelves, then from the other shelf, and then remove the label from the hopper, substantially as described.

38. The combination of a hopper for paper patterns, mechanism for successively separating patterns from said hopper, means for printing upon one face of said folded patterns, means for securing the folds of said patterns, and means for delivering said patterns from the separating means to the printing and securing means, substantially as described.

39. The combination of means for securing the folds of a pattern, means for delivering a folded pattern thereto, presser mechanism for clamping the pattern at said securing means, and means for operating said securing means, substantially as described.

40. The combination of a supply-hopper for folded paper patterns, a feed-plate, means for delivering patterns from said hopper to the feed-plate, means for moving said pattern along said feed-plate to a stapling mechanism, stapling mechanism and means for operating the same, substantially as described.

41. The combination of a supply-hopper for folded paper patterns, a stapling mechanism, wire-feeding mechanism therefor, a feed-plate leading to said stapling mechanism, and means for separating a pattern from said hopper, delivering it to said feed-plate and moving it along said feed-plate to said stapling mechanism, substantially as described.

42. The combination of a supply-hopper for folded paper patterns, a staple-forming mechanism, a wire-feeding mechanism therefor, means for separating a pattern from said hopper and delivering it to said stapling mechanism, a clencher-head adapted to attach a staple to said pattern, and means for operating said clencher-head, substantially as described.

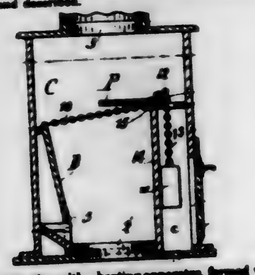
707,788. COMPOSITION OF MATTER. JOHN MURPHY, Columbus, Ohio. Filed Mar. 7, 1902. Serial No. 97,098. (No specimens.)

Claim.—The herein-described composition of matter consisting of crushed hard iron slag, pulverized high-limed cinders, Portland cement, liquor of flints and water, substantially as described.

707,789. AUTOMATIC DRAFT-REGULATING DEVICE. JAMES A. MCATEE, Mahanoy Plane, Pa. Filed Aug. 6, 1901. Serial No. 71,047. (No model.)

Claim.—1. The combination with a heating apparatus formed with a damper-casing; of a pivoted damper mounted in said casing and normally in position to allow a free draft, a rovolvable shaft, a plate mounted on said shaft, and adapted to be moved by a current passing through the damper-casing, an angular extension on said shaft, a chain and a weight attached to said angular extension, and adapted in conjunction with said current to move the said plate, a chain connecting said plate and said damper and enabling them to act simultaneously so that said damper may be closed by the said plate and retained so closed, until restored to normal position

by the hand of an operator, and means for affording facility for such operator to restore said damper and plate to normal position, all substantially as shown and described.



2. The combination with a heating apparatus, formed with a damper-casing, a revolvable shaft mounted in said casing and formed with an angular extension; a plate mounted on said shaft and arranged so that when in normal position, it will not hinder the free flow of the gaseous matter comprising the products of combustion through the said casing, and so that it may be moved in part by said gaseous matter to shut off the draft, a chain and weight attached to said extension, and in connection with said gaseous matter moving said plate to shut off the draft; of a shaft journaled in the said casing, a damper mounted upon said shaft, and arranged to control the draft from the apparatus, a chain connecting said damper and said plate, and enabling them to work simultaneously and to bring said plate into open, and said damper into closed position, so to remain, until restored to normal position by the hand of an operator; and a handle on said last-named shaft to afford facility for said operator to restore said plate and said damper to normal position; all substantially as and for the purpose set forth.

707,790. GRATE AND GRATE-BAR. WILLIAM MCCLAVE, Scranton, Pa., assignor, by mesne assignments, to H. G. Dunham and George G. Brooks, trustees. Filed Dec. 28, 1901. Serial No. 87,614. (No model.)

Claim.—1. A grate comprising grate-bars, a series of fire-bearing finger-caps on some of said bars with ventilating-spaces between them, the said caps being closed on their upper surfaces against a vertical movement of the fuel, and means projecting from the body portion of the bars beneath the spaces between the said finger-caps for preventing the running of fine fuels between the caps before said fuels become coked, while other bars are formed with vertical slots arranged at right angles to the body portions of the bars for introducing more air to the fuel at points where the fuel has become coked sufficiently to prevent the same from running through the grate, substantially as described.

2. An inclined grate comprising side bearer-bars and laterally-extending stationary grate-bars and movable grate-bars supported thereon, the grate-bars at one end of the grate-surface being provided with removable finger-caps having ventilating-openings between their head portions, supporting-fingers upon the grate-bars beneath said ventilating-openings for preventing loose fine fuel from running through the grate at this point, the grate-bars at the lower end of the grate-surface being provided with vertical slots for admitting air to the fuel after the same has become coked, substantially as described.

3. In a grate, the combination of stationary grate-bars and movable grate-bars, the upper bars of the said grate being formed with removable finger-caps having imperforated upper surfaces to prevent fine fuel from running through them, and means projecting from the body portions of the said bars beneath the adjacent edges of the finger-caps to support the caps and prevent a flow of fuel between them, substantially as described.

4. A grate-bar formed with a body portion having flaring recesses formed therein, fingers projecting laterally from the upper edge of said bar, laterally-extending lugs on said fingers, removable caps adapted to rest upon said fingers, means carried by the said caps for engaging the said lugs for holding the caps in position, and means for preventing the caps from becoming disengaged from said lugs, substantially as described.

5. A grate-bar for a furnace, comprising a body portion, and laterally-extending supporting-fingers projecting therefrom, holding-lugs on the said fingers and upon the body portions of the bar, removable caps forming fuel-supporting surfaces on the bar, said caps having laterally-extending lugs for engaging the holding-lugs on the bar, the forward ends of the said caps being also provided with overhanging portions for engaging the holding-lugs on the body portions of the grate-bar, and means for locking the said caps against accidental displacement, substantially as described.

6. In a grate, a series of grate-bars, some stationary, some movable, some also of said bars being formed with a body portion having laterally-extending supporting-fingers, removable finger-caps resting on the said supporting-fingers, lugs for spacing them from said fingers so as to form draft-inlet openings, the top or upper surfaces of said caps being imperforate and extending close to adjacent finger-caps but having air-passages between their adjacent edges, the inner ends of the said caps being inclined and formed with laterally-extending fingers and locking-clips for holding the caps in position, substantially as described.

7. A grate-bar having a body portion formed with laterally-projecting supporting-fingers, a series of fuel-supporting finger-caps arranged with their edges overhanging the edges of adjacent fingers, the said caps having web portions and being spaced a sufficient distance above the said supporting-fingers to form air-passages between the caps and the fingers, spaces being also left between the web portions of the fingers and the said supporting-fingers to provide sufficient draft for fuel carried by the bar, substantially as described.

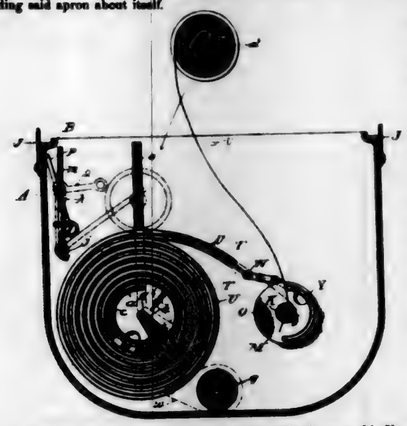
8. A grate-surface made up of grate-bars having body portions and enlarged supporting end portions projecting laterally therefrom, a series of cap-supporting fingers also projecting laterally from said body portion, and a series of fuel-supporting finger-caps mounted between the said supporting-fingers and overlapping their edges, the caps adjacent to the end supporting portions of the bars overlapping the same, substantially as described.

707,791. APPARATUS FOR DEVELOPING PHOTOGRAPHIC FILMS. ARTHUR W. MCCURDY, Washington, D. C., assignor to Eastman Kodak Company, Rochester, N. Y., a Corporation of New York. Filed Mar. 29, 1900. Serial No. 10,663. (No model.)

Claim.—1. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against the admission of actinic rays; a rotary device mounted therein; a flexible apron connected at one end to said rotary device, said apron consisting of a web provided with means for holding the apron in a series of separated layers when wound up; a rotary device connected to the opposite end of said apron; and means for connecting the ends of a flexible photographic film to said rotary devices and maintaining the film in position upon the apron.

2. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against actinic rays; a flexible apron or support mounted therein having its body portion formed of a sheet of celluloid and provided with means for holding the apron in a series of separated layers when wound up; and means for winding the apron about itself in opposite directions.

3. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against actinic rays; a flexible apron or support mounted therein, the body portion of said apron consisting of a sheet of celluloid having openings near its edges; projections extending up from the edges of said apron; and means for winding said apron about itself.



4. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against the admission of actinic rays; a flexible apron or support mounted therein, said apron having its body portion formed of celluloid; projections extending up from said apron near its side edges; means for winding said apron about itself in opposite directions; and means also mounted within the box for holding the ends of a photographic film and maintaining the body of the film proper in close contact with the body of the apron.

5. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle; a cover therefor having an opening formed therein; actinic-proof material mounted within said opening; and lids G, H, pivotally connected to the cover over said actinic-proof material.

6. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle; a cover therefor having an opening formed therein; a sheet of actinic-proof celluloid mounted in the opening, one portion of said sheet being treated so that it will diffuse the light-rays; and lids pivotally connected to the cover over said celluloid sheet.

7. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle; a cover therefor having an opening therein; a sheet of celluloid mounted in said opening and proof against the passage of actinic rays, one portion of the celluloid sheet being ground; and lids G, H, pivotally mounted upon the cover over said celluloid sheet.

8. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle; a cover therefor having an opening formed therein; a sheet of celluloid proof against the passage therethrough of actinic rays, one portion of the sheet being ground; and means for cutting off the direct admission of light-rays to the interior of the apparatus through the unground portion while permitting the operator to view the film through said portion.

9. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against the admission of actinic rays; a flexible apron or support mounted within said box; means for winding said apron about itself with a flexible photographic film thereon; a shaft *j* mounted within the box and provided with outwardly-extending arms, one of said arms being adjustable along the length of the shaft; and a spring for normally rotating said shaft and pressing the arms in a downwardly direction.

10. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against the admission of actinic rays; a flexible apron or support mounted therein; means for winding said apron about itself in a series of separated layers with a flexible photographic film thereon; a shaft *j* mounted within the box and provided with outwardly-extending arms *l*, *m*, said arm *m* being adjustable lengthwise of the shaft; a spring for normally pressing said arms in a downwardly direction; and means for locking said shaft to hold the arms in an upright position.

11. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against the admission of actinic rays; means for admitting liquid to said box; and a hollow screw-plug mounted in the box, said plug being formed with an angular or circuitous passage therein to provide for the exit of the air within said box as the liquid enters the same, substantially as and for the purpose described.

12. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against admission of actinic rays; a shaft K mounted therein; disks loosely mounted upon said shaft; means for locking said shaft and the disks together; a flexible apron or support connected at one end to said disks, the body portion of said apron being formed of celluloid and provided with means for holding the same in a series of separated layers when wound up; disks *a*, *b*, rotatably mounted within the box in rear of said shaft K and likewise connected to the opposite end of the apron; and means carried by said disks *a*, *b*, for holding a spool-axle.

13. In a portable apparatus for developing flexible photographic films, the combination of a suitable box closed against the admission of actinic rays; a shaft K mounted therein and having an opening extending therethrough, the body portion of the shaft being cut away adjacent to said opening, substantially as set forth; disks mounted upon said shaft; means for connecting said disks and the shaft together; a flexible apron or support connected to said disks; a second pair of disks *a*, *b* mounted in the box in rear of said shaft and connected to the opposite end of the apron; and means carried by said disks *a*, *b* for engaging and holding a supporting-shaft for a photographic spool.

14. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against admission of actinic rays; a shaft K mounted therein; disks mounted upon said shaft; a series of seats or sockets P formed in the face of one of said disks; a pin connected to the said shaft and adapted to enter said sockets or seats; means for permitting endwise movement of the shaft and holding it in its adjusted position; a flexible apron connected to the disks; a rotatable device mounted in the box in rear of said shaft and connected to the opposite end of the apron; and means carried by said rotatable device for holding a support for a photographic cartridge-spool.

15. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against the admission of actinic rays; a flexible apron or support mounted therein; a rotatable device connected to one end of said apron; a second rotatable device connected to the opposite end of the apron; means carried by said second device for engaging a shaft or axle; and means for unlocking said devices and permitting the withdrawal of the axle, substantially as and for the purpose described.

16. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against the admission of actinic rays; a rotatable device mounted in the forward end of said box; a flexible apron or support connected at one end to said device; disks *a*, *b*, rotatably mounted in the box in rear of said forward rotary device; locking-levers carried by said devices; and arms *p* pivotally secured within the box and adapted and arranged to be thrown down in line with the outer ends of the locking-levers, substantially as and for the purpose described.

17. An apron or support for use in the development of flexible photographic films consisting of a sheet of celluloid having projections extending up therefrom adjacent to its side edges.

18. An apron or support for use in the development of flexible photographic films, consisting of a sheet of celluloid having strips of flexible material secured thereto adjacent to its side edges.

19. An apron or support for use in the development of flexible photographic films, consisting of a sheet of celluloid having strips or bands of rubber secured thereto adjacent to its side edges.

20. An apron or support for use in the development of flexible photographic films consisting of a sheet of celluloid having perforations extending therethrough near its side edges, and a strip of flexible material secured to the face of the sheet intermediate the openings and the edges.

21. An apron or support for use in the development of flexible photographic films, consisting of a sheet of celluloid having projections extending up therefrom adjacent to its side edges, in combination with means for holding a flexible photographic film thereon intermediate said raised edges.

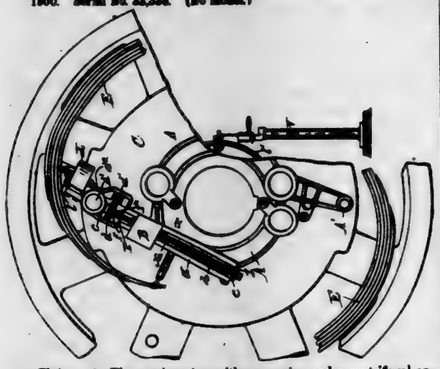
22. An apron or support for use in the development of flexible photographic films, consisting of a sheet of celluloid, having perforations formed therein near its side edges, and strips of rubber sewed to the face of said sheet intermediate the perforations and the edges thereof.

23. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against the admission of actinic rays; a rotatable device mounted therein; a flexible supporting-web connected to said rotatable device; means for holding successive layers of said web in a separated position; and means for connecting the end of a flexible photographic film to said rotatable device.

24. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against the admission of actinic rays; a rotatable device mounted therein; a self-containing flexible web connected to said device; means for holding successive layers of said web in a separated position; and means for connecting the end of a flexible photographic film to said rotary device.

25. In a portable apparatus for developing flexible photographic films, the combination of a suitable box or receptacle closed against the admission of actinic rays; a rotatable device mounted therein; a self-containing flexible web connected to said device; means for holding successive layers of said web in a separated position; means for connecting the end of a flexible photographic film to said rotary device; and means for maintaining a cartridge in proper position with relation to said web.

707,792. ADJUSTER FOR CENTRIFUGAL GOVERNORS. JOHN B. MCINTOSH and JAMES A. SETHOUS, Auburn, N. Y. Filed Oct. 3, 1900. Serial No. 32,333. (No model.)



Claim.—1. The combination with an engine and a centrifugal engine-governor controlling the motor fluid and rotating with the engine-shaft, said engine-governor including a weight adjustable to vary the centrifugal effect of the governor, and a screw for adjusting said weight, of electrically-controlled mechanism rotating with the governor for rotating said screw to adjust the weight while the engine is running.

2. The combination with an engine and a centrifugal engine-governor controlling the motor fluid and rotating with the engine-shaft, said engine-governor including a weight adjustable to vary the centrifugal effect of the governor, and a screw for adjusting said weight, of an electric motor rotating with the governor and connections for rotating said screw, and electrical connections for actuating said motor.

3. The combination with an engine, a centrifugally-acting rotating device including a weight adjustable to vary the centrifugal effect, an eccentric and connections for moving the eccentric by the centrifugally-acting device, connections for controlling the motor fluid by said eccentric, and a screw for adjusting said weight, of electrically-controlled mechanism for rotating said screw to adjust the weight while the engine is running.

4. The combination with an engine, of a centrifugally-acting rotating weight, a pivoted arm carrying said weight, an auxiliary weight carried by and adjustable longitudinally of said arm, an eccentric and connections for moving the eccentric by the centrifugally-acting weight, connections for controlling the motor fluid by said eccentric, a screw for adjusting said auxiliary weight, electrically-controlled mechanism for rotating said screw to adjust the weight while the engine is running.

5. The combination with an engine, of a centrifugally-acting device rotating with the engine-shaft and including a weight adjustable to vary the centrifugal effect, an eccentric and connections for moving the eccentric by the centrifugally-acting device, connections for controlling the motor fluid by said eccentric, a screw for adjusting said weight, and means for rotating said screw to adjust the weight while the engine is running.

6. The combination, with the rotary frame, eccentric and the main centrifugal weight, of a guide carried on said weight, an auxiliary weight mounted longitudinally movable on said guide, a nut on said weight, a screw passing through said nut and pivotally supported on the main centrifugal weight, a gear connected to said screw, a pinion engaging said gear, an electric motor carried on said main centrifugal weight actuating said pinion, and means for controlling said motor.

7. The combination, with the rotary frame, eccentric and the main centrifugal weight, of a guide carried on said weight, an auxiliary weight mounted longitudinally movable on said guide and formed with a nut disposed axially parallel with the guide, a screw passing through said nut, spring-buffers disposed to cushion the auxiliary weight at the ends of its travel, an electric motor carried on the governor-wheel, gearing transmitting motion from said motor to the screw, and means for controlling said motor.

8. The combination, with the rotary frame, eccentric and the main centrifugal weight, of a guide carried on said weight, an auxiliary weight mounted longitudinally movable on said guide and formed with a nut disposed axially parallel with the guide, a screw passing through said nut, spring-buffers disposed to cushion the auxiliary weight at the ends of its travel, an electric motor carried on said main centrifugal weight and actuating said screw, and means for controlling said motor.

9. The combination, with the rotary frame, eccentric and the main centrifugal weight, of a guide carried on said weight, an auxiliary weight mounted longitudinally movable on said guide, a screw moving said weight, stops in the path of said weight to limit the travel thereof, an electric motor carried on the governor-wheel, gearing transmitting motion from said motor to the screw and comprising a friction-drive to allow the motor to slip and continue running after the auxiliary weight has reached the end of its travel, and means for controlling said motor.

10. The combination with the rotary frame, eccentric and the main centrifugal weight, of a guide carried on said weight, an auxiliary weight mounted longitudinally movable on said guide, a screw moving said auxiliary weight, stops in the path of said weight to limit the travel thereof, an electric motor carried on said main centrifugal weight, gear transmitting motion from said motor to the screw and comprising a friction-drive to allow the motor to continue running after the auxiliary weight has reached the end of its travel, and means for controlling said motor.

11. The combination, with the rotary frame, eccentric and the main centrifugal weight, of a guide carried on said weight, an auxiliary weight mounted longitudinally movable on said guide and formed with a nut disposed axially parallel with the guide, a screw passing through said nut, spring-buffers disposed to cushion the auxiliary weight at the ends of its travel, an electric motor carried on the governor-wheel, gear transmitting motion from said motor to the screw, a friction-drive interposed in said gearing to allow the motor to slip and continue running after the auxiliary weight has reached the end of its travel, and means for controlling said motor.

12. The combination, with the rotary frame, eccentric and the main centrifugal weight, of a guide carried on said weight, an auxiliary weight mounted longitudinally movable on said guide and formed with a nut disposed axially parallel with the guide, a screw passing through said nut, spring-buffers disposed to cushion the auxiliary weight at the ends of its travel, an electric motor carried on said main centrifugal weight, gear transmitting motion from said motor to the screw and comprising a friction-drive to allow the motor to continue running after the auxiliary weight has reached the end of its travel, and means for controlling said motor.

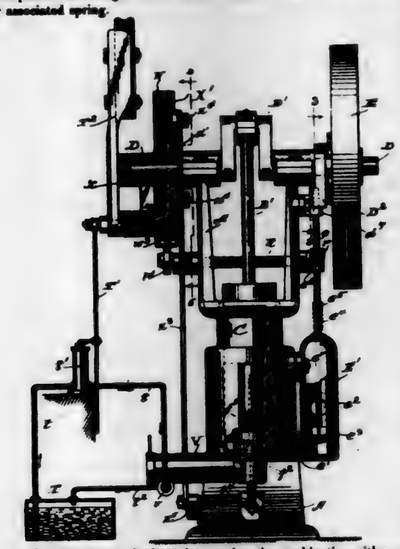
13. The combination, with the rotary frame, eccentric and the main centrifugal weight, of a guide carried on said weight, an auxiliary weight mounted longitudinally movable on said guide and formed with a nut disposed axially parallel with the guide, a screw passing through said nut, and mounted in bearings on the main centrifugal weight, a disk fastened to said screw, a companion disk mounted longitudinally movable on the screw and locked from turning thereon, a gear sustained by the interposition of its web between said disks, a nut connected to the aforesaid screw, a spring interposed between said nut and movable disk to clamp the gear between the disks, a motor carried on said arm actuating the gear, and means for controlling said motor.

14. The combination, with the rotary frame, eccentric and the main centrifugal weight, of a guide carried on said weight, an auxiliary weight mounted longitudinally movable on said guide and formed with a nut disposed axially parallel with the guide, a screw passing through said nut, spring-buffers disposed to cushion the auxiliary weight at the end of its travel, a friction-drive consisting of a disk fastened to the screw, a companion disk mounted longitudinally movable on the screw and locked from turning thereon, a gear sustained by the interposition of its web between said disks, a nut connected to the aforesaid screw, a spring interposed between said nut and movable disks, a motor carried on said arm and actuating the gear, and means for controlling said motor.

707,793. GASOLENE-ENGINE. ELOY T. MCKAIG, Chicago, Ill. Filed Aug. 26, 1901. Serial No. 73,256. (No model.)

Claim.—1. In a gasolene or hydrocarbon engine, the combination with the cylinder having an inlet-valve, and an outlet-valve having a stem, of a governor for controlling the engine, consisting of a rotating disk or wheel having spring-held weighted arms pivoted thereto and adapted to move in unison and provided with a brake, and of a collar, having a socket to receive the valve-stem and a sleeve with which the brake connects to move the collar into the path of the valve-stem.

2. In a gasolene or hydrocarbon engine, the combination with the cylinder having inlet and outlet valves, of a governor for controlling the engine, consisting of a rotating disk or wheel having connected weighted arms pulled toward each other by spring tension and adapted to be forced apart by centrifugal action of the weights as the wheel revolves and provided with a brake, and of a collar on the shaft of the wheel, having a sleeve in the path of the brake and a socket-piece provided with a recess in the path of the stem of the outlet-valve, said collar and brake being adapted to move together when the weights overcome the tension of their associated spring.



3. In a gasolene or hydrocarbon engine, the combination with a cylinder having an inlet-valve and an exhaust-valve provided with a stem, springs holding said valves normally in their seats, the spring of the exhaust-valve being somewhat stronger than the spring of the inlet-valve, of a governor for controlling the inlet-valve, consisting of a rotating disk or wheel having spring-held weighted arms pivoted thereto and moving outwardly and inwardly from the shaft thereof in unison under spring and centrifugal force, respectively, and provided with a brake-shoe, and of a collar loosely mounted on said shaft, having a sleeve with which the brake-shoe is adapted to cooperate, and provided with a socket-piece embracing the upper end of the valve-stem and having a buffer adapted to be projected within the path of the valve-stem to retain the valve in open position when the collar and brake-shoe move together.

4. In a vapor-engine, the combination with a cylinder and piston having a shaft, and an exhaust-valve for said cylinder having a valve-stem, of a collar loose on the shaft and having a flange and a socket-piece yieldingly held against movement with the shaft, said socket-piece being adapted to cooperate with the valve-stem for the purpose described, a disk or wheel provided with connected spring-pressed weighted arms pivoted thereto, and a brake on one of the arms and adapted to engage the flange.

5. In a vapor-engine, the combination with a cylinder and piston provided with a shaft, and an exhaust-valve for said cylinder having the valve-stem, of a collar yieldingly held against movement therewith and comprising a flange and a socket-piece, said socket-piece being adapted to cooperate with the valve-stem for the purpose described, a disk or wheel, weighted arms pivoted thereto and carrying a brake normally held out of engagement with the collar by spring-pressure and adapted to engage therewith by the centrifugal action of the weights.

6. In a vapor-engine, the combination with a cylinder and a piston connected to a shaft, of a collar loose on the shaft and having a sleeve and a socket-piece provided with a buffer, a guide within the socket, an interposed spring, a reciprocating valve-stem in the guide, and a disk or wheel having weighted arms pivoted thereto provided with a brake, a link connecting the arms, and a spring for normally counteracting the centrifugal action of the weights.

7. In a vapor-engine, the combination with a cylinder, a piston, and a crank-shaft, of a collar on the shaft having an annular flange and a socket-piece provided with a recess, a buffer-plate in the recess, a spring-chamber in one side of the socket-piece, a guide within the socket, a spring in the chamber holding the buffer out of alinement with the guide, a valve-stem within the guide, and a disk or wheel having spring-pressed weighted arms pivoted thereto and provided with a brake engaging the flange under the centrifugal action of the arms.

8. In a vapor-engine, the combination with the cylinder having an inlet-valve and an outlet-valve having a stem, a spring for moving said outlet-valve in one direction, and governing mechanism for holding the outlet-valve open, comprising a rotating disk, weighted arms pivoted thereto and carrying a brake, a link connecting said arms, a spring for normally counteracting the centrifugal action of said weights, and a collar movable on the shaft adapted to be engaged by said brake and moved into the path of the stem.

9. In a vapor-engine, the combination of a cylinder having an inlet and an outlet valve, a stem upon the outlet-valve, a spring for moving said valve in one direction, and a governor for holding said outlet-valve open, comprising a rotating-disk or wheel having weighted arms D^4 pivoted thereto and provided with a brake d, a link D^5 connecting said arms, a spring D^6 for normally counteracting the centrifugal action of said arms, a collar D^2 having a sleeve d^3 and a socket-piece provided with a recess, a buffer d^5 in the recess, and a spring d^6 holding the buffer out of the path of the valve-stem.

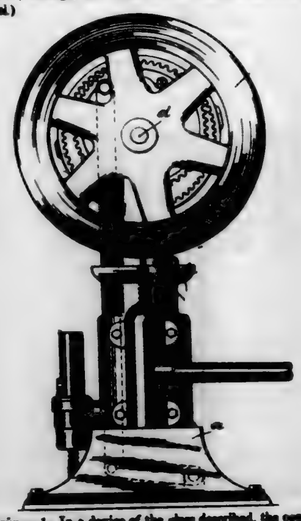
10. In an engine of the class described, the combination with the cylinder having an inlet and an outlet valve, of a governor for controlling the engine consisting of a rotating disk or wheel, a spring-held weighted arm pivoted thereto and provided with a brake, and mechanism operated by said brake to hold the outlet-valve open.

11. In an engine of the class described, the combination with the cylinder having inlet and outlet valves, of a governor for controlling the engine consisting of a rotating disk or wheel having a spring-held weighted arm adapted to be moved outward by centrifugal action and provided with a brake, and a collar on the shaft of the wheel, having a sleeve in the path of the brake and a socket-piece in the path of the stem of the outlet-valve, said collar and brake being adapted to move together when the weight overcomes the tension of the associated spring.

12. In an engine of the class described, the combination with a cylinder and piston provided with a shaft, of a collar yieldingly held against movement therewith and comprising a sleeve and socket-piece, a disk or wheel, a weighted arm pivoted thereto and carrying a brake normally held out of engagement with the collar by spring-pressure and adapted to engage therewith by the centrifugal action of the weight

13. In an engine of the class described, the combination with the cylinder having an inlet-valve and an outlet-valve having a stem, a spring for moving said outlet-valve in one direction, and a governor for holding said valve open comprising a rotating disk, a weighted arm pivoted thereto and carrying a brake, a spring normally counteracting the centrifugal action of said weight, and a collar movable on the shaft and adapted to be engaged by said brake and moved into the path of the stem.

707,794. LUBRICATING APPARATUS FOR ENGINES. ELOY T. MCKAIG, Chicago, Ill. Filed Dec. 9, 1901. Serial No. 86,184. (No model.)



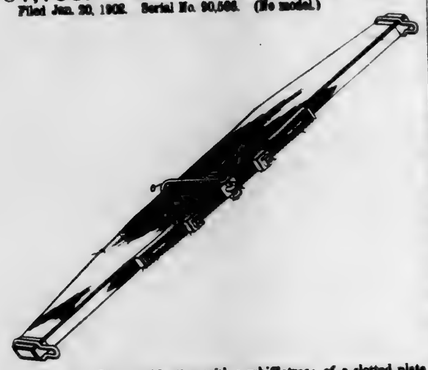
Claim.—1. In a device of the class described, the combination with the cylinder, of the piston adapted to reciprocate therein, a channel con-

nected with the cylinder and adapted to receive a supply of the lubricant, and a wick extending into said channel and having its other end in position to contact with the piston; substantially as described.

2. In a device of the class described, the combination with the cylinder, of the piston adapted to reciprocate therein, a channel connected with the cylinder and adapted to receive a supply of the lubricant, a wick extending into said channel and having its other end in position to contact with the piston, and means for holding said wick in said channel; substantially as described.

3. In a device of the class described, the combination with the cylinder, of the piston adapted to reciprocate therein, a channel connected with the cylinder and adapted to receive a supply of the lubricant, a wick extending into said channel and having its other end in position to contact with the piston, and means for holding said wick in said channel consisting of the annular spring-clip *j*; substantially as described.

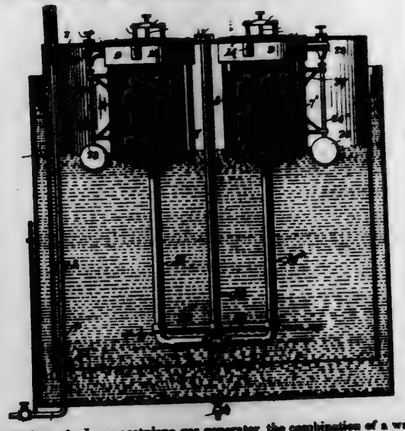
707,795. WHIFFLETREE. ROBERT W. MCKINLEY, Ripley, Ohio. Filed Jan. 20, 1902. Serial No. 90,566. (No model.)



Claim.—1. The combination with a whiffletree; of a slotted plate slidably mounted thereon, teeth upon said plate, toothed blocks normally engaging the teeth of the plate, means for clamping said blocks against the plate whereby said plate is locked in adjusted position, and a pivot-bolt for the whiffletree, secured to the slidable plate.

2. The combination with a whiffletree; of bolts extending therefrom, a slotted plate slidably mounted thereon, teeth upon the plate, toothed blocks upon the bolts and engaging the teeth of the plate, nuts upon the bolts for clamping the blocks and plate together, a pivot-bolt for the whiffletree, secured to the plate.

707,796. ACETYLENE-GAS GENERATOR. SYRANDA L. NEWLIN and JESS MATHESON, Kingriver, Cal.; said Newlin assignor to said Matheson. Filed Mar. 27, 1902. Serial No. 100,239. (No model.)



Claim.—1. In an acetylene-gas generator, the combination of a water-tank, a gas-holder movably mounted therein, a gas-generator carried by the gas-holder and comprising a casing having an inlet for water and a discharge for the generated gas, means for closing the inlet to prevent access of water to the generator, a valve controlling the outlet, means for automatically opening said valve, and means for holding said valve closed against the pressure of the opening device, substantially as described.

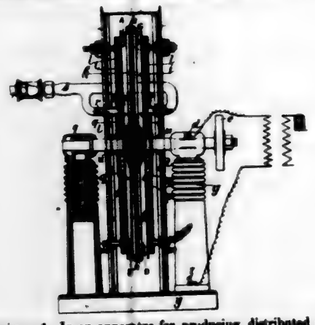
2. In an acetylene-gas generator, the combination of a water-tank, a bell or gas-holder movable therein, a generator carried by the bell and comprising a casing having an inlet for water and an outlet for the generated gas, a carbid-basket arranged within the casing, a valve for opening and closing the inlet to regulate the supply of water to the casing, means for holding the outlet-valve closed, and a float carrying a tappet device adapted to open said valve in a predetermined position of the valve when the said valve-closing device is retracted, substantially as specified.

3. In an acetylene-gas generator, the combination of a water-tank, a bell or gas-holder arranged therein, a generator carried by the gas-holder and comprising a casing having a carbid-basket arranged therein and provided with a depending pipe for the inlet of water thereto, a valve-controlled discharge regulating the outflow of gas from the generator, a rod for opening the valve of said discharge, a float for operating said rod, and means for holding the valve seated against the pressure of the rod, substantially as set forth.

4. In an acetylene-gas generator, the combination of a water-tank, a bell or gas-holder arranged therein, generators carried by the gas-holder and each comprising a casing having a carbid-basket arranged therein and provided with a depending water-supply pipe, the water-supply pipes of the two generators having their lower ends arranged in close relation, a valve-controlled discharge regulating the outflow of gas from each generator, means for holding the valves thereof closed against their seats, means for opening the valves in a predetermined position of the gas-holder when said valve-holding means are retracted, and means common to both pipes for opening or closing either of the water-inlet pipes at will, substantially as specified.

5. In an acetylene-gas generator, the combination of a water-tank a gas-holder arranged therein, generators carried by the gas-holder, each generator comprising an imperforate casing containing a perforate carbid-holder and having a pendent water-inlet pipe, the two pipes having their lower ends arranged in close relation, a valve-controlled discharge regulating the outflow of gas from each generator-casing, means for holding the valves thereof closed against their seats, rods for opening the valves when the valve-closing means are retracted, floats for bringing said rods into action when the gas-holder descends to a predetermined position, a valve adapted to close the lower end of either of the aforesaid water-inlet pipes, a rod connected to said valve, and means for operating the rod, substantially as set forth.

707,797. ROTARY APPARATUS FOR THE PRODUCTION OF DIFFUSED ELECTRIC DISCHARGES. MARIUS OTTO, Neuilly, France. Filed Nov. 12, 1901. Serial No. 82,080. (No model.)



Claim.—1. In an apparatus for producing distributed electric discharges, the combination with electrodes moving relatively to each other, of dielectric material interposed between said electrodes, substantially as described.

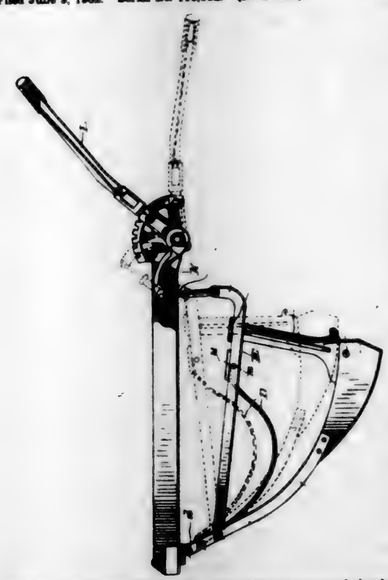
2. In an apparatus for producing distributed electrical discharges, a pair of stationary conducting-disks having each a covering or facing of dielectric material, and a conducting-disk movably mounted between the dielectric-covered faces of the stationary conducting-disks, substantially as described.

3. In an apparatus for producing distributed electrical discharges, a pair of hollow stationary conducting-disks arranged parallel to each other, means for supplying a cooling medium thereto, a covering or facing of dielectric material on the opposing faces of said disks, and a disk of conducting material rotatably mounted between said dielectric-covered faces, substantially as described.

707,798. PARER AND SLICER. GEORGE W. PAUL, Pittsburg, Pa. Filed Mar. 16, 1901. Serial No. 51,510. (No model.)

Claim.—A paring and slicing implement which comprises a handle and frame formed of a single piece of wire doubled upon itself, the ends of the two strands being extended in parallel relation to one another, a slicer comprising an integral sheet-metal plate having an elongated slot formed therein extending in proximity to the sides of said plate, an integral curved extension having a knife-edge on its lower face carried by one side of said slicer, the said ends of the frame engaging the outer face of said slicer and extending to a point below said slot, the sides of said plate being bent over to engage said frame except at the point of the curved extension, the part above said slot being bent at an angle and having its sides doubled upon themselves from a point at the ends of said frame, the upper end, of said inclined part being straight, the walls of said slot being bent in opposite directions, and a knife-edge on one of said walls, substantially as described.

707,799. GRAIN-DRILL. OCTAVE A. POIRIER, Minneapolis, Minn. Filed June 9, 1902. Serial No. 110,902. (No model.)



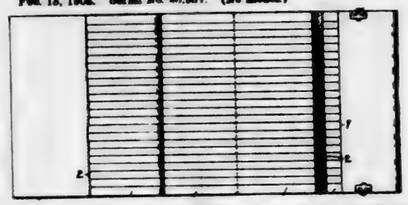
Claim.—1. The combination, with a suitable frame and the draw-bars pivotally connected to said frame, of guide-bars pivotally connected to said draw-bars, a head-block secured to the forward ends of the draw-bars and a spring having one end connected to said head-block, its opposite end forming a sliding bearing with a plate on the guide-bars and its intermediate portion bearing upon the draw-bars, substantially as described.

2. The combination, with the frame and the draw-bars pivoted thereto, of the guide-bars pivoted to said draw-bars and provided with means for adjusting them and the spring having one end secured to said draw-bars and its other end forming a sliding bearing with a plate on the guide-bars, substantially as described.

3. The combination, with the pivoted draw-bars, of the head-block arranged between the forward ends of said draw-bars, the guide-bars pivotally connected to said draw-bars and a spring having one end secured to said head-block and its other end forming a sliding bearing with a plate on the guide-bars, substantially as described.

4. The combination, with the draw-bars, of the head-block secured to the forward portions of said draw-bars, the guide-bars arranged above said draw-bars and the spring having one end connected to said head-block and the other end forming a sliding bearing with a plate on said guide-bars, the intermediate portion of spring forming a bearing on said draw-bars, substantially as described.

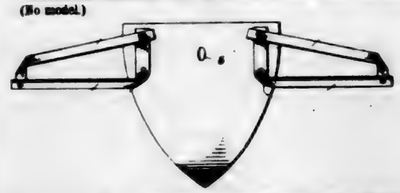
707,800. SPELLING-MANUAL. ROBERT B. ELGIDON, Washington, D. C., assignor to William B. Stockett & Co., a firm consisting of William B. Stockett and Charles A. Stockett, Washington, D. C. Filed Feb. 13, 1902. Serial No. 93,867. (No model.)



Claim.—1. A book consisting of a cover provided at one edge with a pocket opening toward the central fold of the cover, a plurality of leaves permanently secured or bound at said central fold of the cover, and having a weakened line parallel with the bound edge and approximately midway between the bound and free edges; the pocket of the cover being of a size to receive the half-leaves that may be severed, substantially as described.

2. A book consisting of a cover extended at one edge and folded to form a pocket, a plurality of leaves permanently secured or bound at the central fold of the cover and having a weakened line approximately midway between the edges; the pocket of the cover being of a size to receive the half-leaves that may be severed on said weakened line, substantially as described.

707,801. WEED-CUTTING ATTACHMENT FOR PLOWS. JOHN M. ROBINSON, Goldthwaite, Tex. Filed May 29, 1902. Serial No. 108,467. (No model.)



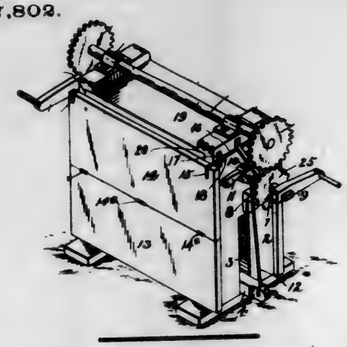
Claim.—1. In a cutting attachment for plows, the combination of the plow-shovel, the cutting-blades attached to the shovel, and brace-rods connecting the outer ends of said blades with said shovel, substantially as set forth.

2. In a weed-cutting attachment for plows and cultivators, the combination of the plow-shovel, the cutting-blades attached to the shovel and having their attaching ends bent and twisted at an angle to said blades so that when bolted to said shovel the blades will lie at the proper cutting angle, and brace-rods connecting the outer ends of said blades to the plow-shovel, substantially as set forth.

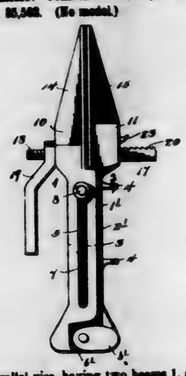
707,802. BALING-PRESS. JOHN P. SHAW, Aberdeen, Miss. Filed Feb. 20, 1901. Serial No. 48,982. (No model.)

Claim.—In a baling-press, the combination with the casing having a sliding top and hinged side doors and the ends of the casing having vertically-elongated slots therein; of a follower having arms projecting through said slots, a drive-shaft mounted on top of the casing having gear-wheels on opposite ends, brackets secured to the opposite ends of the casing having stub-shafts provided with drums journaled therein and in the ends of the casing, said stub-shafts having on their outer ends gear-wheels meshing with the gear-wheels on the drive-shaft, the inner ends of said stub-shafts being provided with ratchet-wheels meeting with suitably-arranged pawls, and ropes secured to the drums and the bearings of the projecting arms of the follower, and the cranks secured to the stub-shafts to rotate the same so as to wind the ropes on the drums thereby moving the follower vertically upward toward the top of the press, substantially as specified.

707,802.



707,808. CLAMP. JOHN A. SMITH, Dayton, Ohio. Filed Dec. 12, 1901. Serial No. 85,562. (No model.)

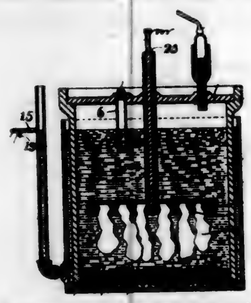


Claim.—A parallel vise, having two beams 1, and 2; beam 1, consisting of a vise-jaw 14, and below said jaw and integral therewith, a square part 10, provided with a smooth-bore horizontal perforation 12, and extending from the lower end and front face of said square part, a longitudinally-slotted arm 1', just one-half the thickness of said square part; a short arm extending rearwardly from the lower end of said arm; a bearing 6', extending inwardly from the rear end of said short arm; beam 2, consisting of a vise-jaw 15, a square part 11, provided with a smooth-bore rectangular perforation 13, a slotted arm 2', extending from the rear face of said square part; a short arm, extending inwardly from the lower end of said arm; a bearing extending inwardly from the front end of said arm; cross toggle-levers 5, and 6, their lower ends pivoted to the bearings 5', and 6', respectively, their upper ends perforated; bolts 8, and 9, passing through the perforations in the upper ends of said arms, and through the slots 3, and secured loosely, so that they may slide up and down in said slots; a bar 17, having one end cylindrical and threaded, and working in said smooth-bore perforation 12; a lever-handle nut working on the threads of the cylindrical part of said bar 17, and against the outer face of said beam, the other end of said bar working in the rectangular smooth-bore perforation 13, and having in its upper edge, notches 20; a dog 21, provided with a thumb-lift 23, and with teeth 22, adapted to catch in the notches 20, of said bar; said beams adapted to be moved to the right and left in parallel lines, and to be held in place by said bar, a dog and lever-handle nut, substantially as shown and described and for the purposes set forth.

707,804. ELECTROLYTIC CELL. ADOLPH SOMER, Cambridge, Mass. Filed Aug. 17, 1899. Serial No. 727,681. (No model.)

Claim.—1. In an apparatus for the electrolysis of saline solutions, an anode-compartment, a cover therefor, a cathode, an anode in said compartment having a non-conducting horizontal flat upper surface, and a tube for the introduction of material to be electrolyzed, said tube leading through said cover and terminating above said anode.

2. In an apparatus for the electrolysis of saline solutions, an anode-compartment, a cover therefor, an anode in said compartment, a cathode, and a liquid seal or water-joint leading through said cover, said liquid seal or water-joint having a high outer wall or cup, and a relatively low inner tube providing an unobstructed passage to permit of the introduction of a liquid into the compartment and the discharge of the liberated gas.



3. In an apparatus for the electrolysis of saline solutions, an anode-compartment, a cover therefor, a cathode, a tube for the discharge of gas, a cup surrounding said tube and forming therewith an annular receptacle for the reception of liquid, the outer wall of said cup projecting above said tube so that liquid introduced in said cup will flow through said tube into the compartment, and a gas-conducting pipe having its end placed in said annular receptacle whereby the escape of gas except through said pipe is prevented by the liquid in said receptacle.

4. In an apparatus for the electrolysis of saline solutions, an anode a cathode, a diaphragm consisting of a layer of insoluble granular non-conducting material and a foraminous non-fibrous sheet of conducting material supporting said granular material, and means for maintaining said sheet out of contact with said cathode.

5. In an apparatus for the electrolysis of saline solutions, an anode, a cathode, a diaphragm consisting of a layer of insoluble granular non-conducting material, a foraminous non-fibrous sheet of conducting material supporting said granular material, means for maintaining said sheet out of contact with said cathode, and a gas-tight non-conducting tube which forms the vertical wall of the anode-compartment and is placed upon the said foraminous sheet.

6. In an apparatus for the electrolysis of saline solutions, an anode, a cathode, a diaphragm consisting of a layer of insoluble granular non-conducting material and a foraminous non-fibrous sheet of conducting material, a gas-tight non-conducting tube which forms the vertical wall of the anode-compartment and is placed upon the said sheet, and electrically non-conducting means for supporting the said sheet and tube, and maintaining said sheet out of contact with said cathode.

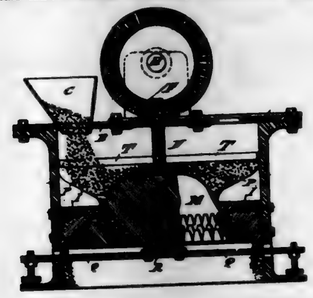
7. In an apparatus for the electrolysis of saline solutions, a conductive receptacle, a wall forming an anode-compartment, an anode in said compartment, a cathode, a diaphragm separating the anode and cathode and located at the bottom of the anode-compartment, and a support for the said wall and diaphragm, said support being made of a non-conducting material and having openings on a plane with the lower surface of the diaphragm, substantially as described.

8. An apparatus for the electrolysis of saline solutions comprising a metallic tank which alone constitutes the cathode, an open-ended tube in said tank, the walls of which are non-conducting and impermeable to gas, an anode in said tube, a porous diaphragm closing the bottom of said tube, and a separable cover closing the top of said tube, substantially as described.

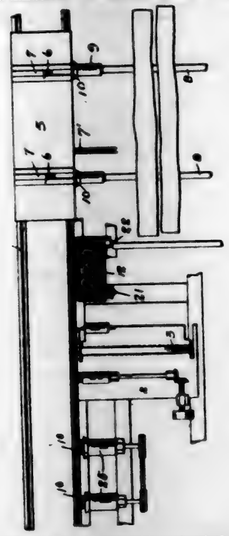
9. An apparatus for the electrolysis of saline solutions, comprising a metallic tank, which constitutes the cathode, a non-conducting impervious tube in said tank, an anode in said tube, a non-conducting open support for said tube, and a diaphragm consisting of a foraminous non-fibrous sheet closing the bottom of said tube and held between said tube and said support, and a layer of sand or other insoluble granular non-conducting material on said sheet.

707,805. MILL. ADOLPH THIESS, Paris, France. Filed Apr. 11, 1901. Serial No. 55,343. (No model.)

Claim.—In the improved grinding-mill, the combination with a cylindrical casing and perforated cover-plate removably secured on the same of a stationary inverted cup within the casing, stepped annular rows of grinding-teeth, having curved bodies described in the arc of the annulus on the inner wall of said cup, a rotatable grinding-cone arranged in said cup, correspondingly-stepped annular rows of curved grinding-teeth on the outer wall of said cone and extending into the intermediate spaces between the teeth of said cup, a vertical shaft carrying said cone and suitably journaled in bearings, means for actuating said shaft, a hopper mounted on the cover-plate of the casing, a circular screen arranged beneath said hopper and secured to and rotating with said vertical shaft to uniformly distribute grains to the cup and cone, means for preventing grains from dropping upon the upper surface of the cups, and means for adjusting said shaft vertically, substantially as and for the purpose set forth.



707,806. LUMBER-CONVEYER. EDWIN E. THOMAS, St. Paul, Minn., assignor of one-half to Union Iron Works, Minneapolis, Minn., a Corporation of Minnesota. Filed Jan. 21, 1902. Serial No. 90,060. (No model.)



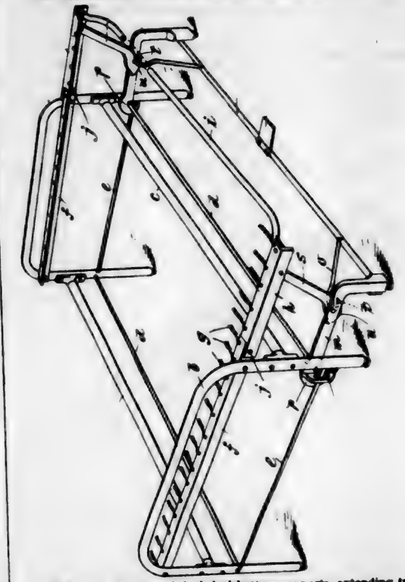
Claim.—1. The combination, with a saw, log-deck and carriage, of an endless conveyer belt or bed arranged below the level of the carriage-blocks and whereon the lumber falls that is cut on the backward or return movement of the carriage, said bed being composed of a series of slats or bars arranged at intervals, ribs provided lengthwise of said bars, and faces provided at or near the inner ends of said bars and inclined toward the middle of the same to receive the lower edges of the lumber as it falls from the carriage.

2. The combination, with a double-cutting band-mill and the log-carriage, of rolls arranged to receive the lumber as it falls from the carriage, cone-shaped or beveled faces provided near the inner ends of said rolls to receive the lower edges of the lumber and direct it to its proper flatwise carrying position on said rolls and an endless lumber-conveying bed or belt having slats provided near their inner ends with inwardly-inclined surfaces.

3. In a sawmill, a lumber-conveyer comprising a series of bars or slats and links connecting the same, said bars being provided near one end with inclined faces to engage the lumber and direct it to its proper carrying position on said bars, and means for driving said conveyer.

4. The combination, with a band-saw mill, of a lumber-conveyer bed or belt provided near the saw and comprising a series of metal bars or slats and links connecting the same, and projections or teeth provided near the inner ends of said bars and having inclined faces to receive and direct the lumber to the proper carrying position on said bars and said projections being also adapted to act as guides to prevent the lumber from coming in contact with the saw while traveling over said conveyer.

707,807. COUCH-BED. FRANCIS H. TINKHAM, Springfield, Mass. Filed Apr. 26, 1901. Serial No. 104,844. (No model.)



Claim.—1. In a couch-bed, bed-bottom supports extending transversely of the couch, a side frame pivotally attached to the ends of said bed-bottom supports, arms depending from the side frames, a support for said side frames slidable in and out from beneath the couch on the floor, devices on said side-frame support, and on said arms adapted to become engaged by the upward-swinging movement of the side frame, whereby the side-frame support may be withdrawn from under the couch, together with automatically-operating interlocking means between said arms and the side-frame support operable at the limit of the outward movement of the latter.

2. In a couch-bed frame, bed-bottom supports, a side frame pivotally attached thereto and adapted to swing from a horizontal, downwardly to a vertical position, or vice versa; a frame slidable on the floor and on the frame of the couch, in and out under the latter, a device on said sliding frame for interlocking with the frame of the couch at the limit of its outwardly-sliding movement, and a connection between the sliding frame and the side frame, whereby the upwardly-swinging movement of the latter will operate to draw out said sliding frame from under the couch.

3. In a couch-bed frame, bed-bottom supports, a side frame pivotally attached thereto and adapted to swing from a horizontal to a vertical position downwardly, and vice versa; a frame slidable toward and from the couch under said side frame, an arm on the latter to engage said slidable frame on the outward movement of the latter, whereby said slidable frame is rigidly supported in horizontal position; a device on said slidable frame for interlocking with the couch-frame when the side frame is extended, and means for pivotally rocking said slidable frame on said arm to disengage the former from its engagement with the couch-frame.

4. In a couch-bed frame, bed-bottom supports, a side frame pivotally attached thereto and adapted to swing from a horizontal downwardly to a vertical position, or vice versa; a frame slidable on the floor and on the frame of the couch, in and out under the latter; a device on said sliding frame for interlocking with the frame of the couch at the limit of its outwardly-sliding movement, an interlocking connection between the sliding frame and the side frame, and means whereby, upon the inward movement of the sliding frame, the disengagement of the interlocking connection between said side frame and said sliding frame may be effected.

5. The combination in a couch-bed, of a side frame pivotally attached thereto, which may be swung upward into horizontal position in the plane of the top of the couch; of a frame slidable on the floor in and out from under the couch, and a pivoted arm constituting a vertical brace between said side frame and slidable frame and adapted to engage the sliding frame, to draw it outwardly by the upward movement of the side frame, and interlocking devices between said arm and the sliding frame to lock the arm in frame-supporting position at the limit of the upwardly-swinging movement of said frame.

6. The combination in a couch-bed, of a side frame pivotally attached thereto, which may be swung upward into horizontal position in the plane of the top of the couch, of a frame slidable on the floor in and out from under the couch, and a pivoted arm constituting a vertical brace between said side frame and slidable frame, adapted to be automatically locked in side-frame-supporting position by the outward movement of the sliding frame, and means on the couch whereby said arm may be automatically disengaged from the sliding frame by the inward movement of the latter.

707,808. WINDOW. HUGO VETTEL, Newark, N. J. Filed June 20, 1902. Serial No. 112,466. (No model.)

Claim.—1. The combination of a window-casing provided with parallel front and rear guide-grooves and parting-strips having recesses adjacent to the window-sill, switch-tongues pivoted in said recesses and adapted to form inclined channels with the parting-strips, and sashes guided along said grooves and provided with pivots at their lower ends and locking devices at their upper ends, the lower of said sashes being permitted to be shifted from one guide-groove into the other by means of the switch-tongues, substantially as set forth.

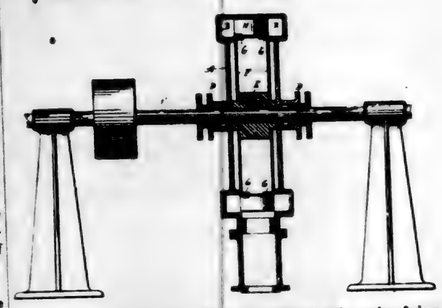
2. The combination, with a window-casing provided with parallel guide-grooves, of switch-tongues located between said guide-grooves near the sill, said switch-tongues being pivoted at their lower ends to the window-casing, sashes guided along the guide-grooves and provided with pivots at their lower ends projecting into said guide-grooves, and shiftable rollers at the upper ends of the sashes adapted to move in said guide-grooves, substantially as set forth.

3. The combination of a window-casing provided with parallel front and rear guide-grooves, pivoted switch-tongues located in recesses in the parting-strips near the window-sill, said rear guide-grooves having adjacent to the window-sill sliding sashes, pivot-rollers at the lower corners of said sashes, and locking devices having rollers at the upper corners of said sashes, said rollers being adapted to move in said guide-grooves, each sash being adapted to be tilted inwardly when the locking-pins are withdrawn and the lower rails of the same are placed in the recesses of the window-casing, substantially as set forth.

4. The combination of a window-casing provided with independent front and rear guide-grooves and recesses at the rear guide-grooves, sashes guided along the same, pivot-rollers at the lower ends of the sashes, weighted sash-cords connected with said pivot-rollers, switch-tongues located in recesses in the parting-strips, said switch-tongues forming inclined channels for shifting the lower sash from the front guide-grooves into the rear guide-grooves and into said recesses of the casing so as to permit the tilting of the sashes for cleaning without interference with the sash-cords, substantially as set forth.

707,809. MOTOR. MAXIMILIAN VILLARDI, New Haven, Conn. Filed Aug. 25, 1901. Serial No. 73,003. (No model.)

Claim.—1. A motor comprising a shell or case formed with a series of chambers in opposite sides opening into the shell but otherwise closed, a wheel mounted in said shell and formed with a series of peripheral parabolic buckets arranged in line with said chambers across the mouths of which they pass, a tangential inlet-opening through the shell directly in line with and against the tips of said buckets, and an exhaust or discharge opening in the bottom of the shell.



2. A motor comprising a shell or case formed with a series of chambers in opposite sides, a wheel mounted in said shell, said wheel comprising a hub and flanges supported on opposite sides thereof, said flanges turned inward at their outer edges, a series of parabolic buckets secured to the said turned-in edges, said buckets being arranged in line with said chambers across the mouths of which they pass, and an inlet-opening through the case directly in line with and against the tips of the said buckets, substantially as described.

707,810. DENTAL FORM FOR HOLDING TEETH. RAYMOND J. WISNER, Milwaukee, Wis. Filed Jan. 11, 1902. Serial No. 89,204. (No model.)

Claim.—1. As a new manufacture, a so-called dummy jaw or dental form for demonstrating or experimental purposes, provided with a plurality of recesses or sockets for the reception of the roots or covered portions of teeth, substantially as set forth.

2. As a new manufacture, a so-called dummy jaw or dental form for demonstrating or experimental purposes, provided with a plurality of recesses or sockets for the reception of the roots of teeth; teeth located in said sockets or recesses; and means for retaining said teeth in their sockets as set forth.

3. As a new manufacture, a dummy jaw or dental form for demonstrating or experimental purposes, provided with a plurality of sockets or recesses for the reception of the roots of teeth; teeth located in said sockets or recesses; and a packing of adhesive material interposed between the walls of said sockets and the teeth therein, and adapted to adhere to and rigidly retain said teeth in their respective sockets, as set forth.

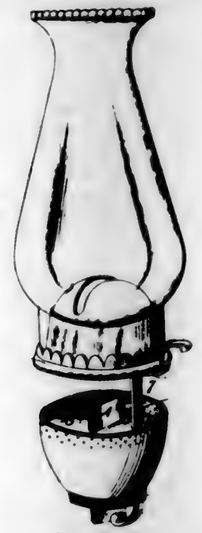
4. As a new manufacture, a dummy jaw or dental form for demonstrating or experimental purposes, formed of flexible material and provided with a series of sockets or recesses for the reception of the roots of teeth; teeth located in said sockets or recesses; and means for retaining said teeth in their sockets, substantially as set forth.

707,811. LAMP-BURNER. THOMAS B. ARNOTT, Sale, Victoria, Australia. Filed Dec. 6, 1901. Serial No. 84,902. (No model.)

Claim.—1. The combination with a burner comprising a body portion and a separable crown, of a lifting device fixedly connected to the crown and having a sliding connection with the body portion, and means carried by the lifting device for engaging the wick-tube of the body portion and holding the separable crown in elevated adjustment above the body portion, substantially as set forth.

2. The combination with a burner comprising a body portion and a separable crown, of a lifting device consisting of an angular strip fixed to the separable crown and having a sliding engagement with the body portion, the upper end of said strip projecting laterally to form a finger-piece and the inner or lower end being formed of spring metal and adapted to engage the wick-tube of the body portion and support the crown portion in elevated position above the same, substantially as set forth.

707,811.



707,812. ALKOXY-CAFFEIN AND PROCESS OF MAKING SAME. FRITZ ACH, Mannheim, Germany, assignor to The Firm of C. F. Boehringer & Soehne, Waldhof, near Mannheim, Germany. Filed Apr. 16, 1898. Serial No. 677,857. (Specimens.)

Claim.—1. In the art of preparing the alkoxy derivatives of chloro-caffein, the process which consists in reacting upon 3'-8-dichloro-caffein with an alcohol.

2. In the art of preparing the alkoxy derivatives of chloro-caffein, the process which consists in boiling 3'-8-dichloro-caffein with methyl-alcohol.

3. In the art of preparing the alkoxy derivatives of chloro-caffein the process which consists in heating chloro-caffein under pressure, together with phosphorus-penta-chlorid and phosphorus-oxy-chlorid in the proportions and under the conditions substantially as stated, then cooling, and then evaporating the resultant liquor and boiling the residue, together with methyl-alcohol, in a reflux, in the proportions and at the temperature, substantially as stated.

4. As a new series of chemical compounds, alkoxy-chloro-caffeins, that is, alkoxy derivatives of chloro-caffein, said compounds being others which may be obtained in the form of crystals and which have the group

$$C_nH_{2n}+1.O.CH_2$$

bound to the atom N in the position (3,) said compounds, moreover, all melting above 100°, centigrade, and all giving a murexid reaction.

5. As a new chemical compound, 3'-methoxy-8-chloro-caffein having the formula above given, and the following properties: it crystallizes in fine shining felted needles, having the melting-point 129° to 130°, centigrade; it is soluble in boiling water, hot alcohol, benzene, aceton, acetic ether and chloroform, and in fuming hydrochloric acid; it gives a strong murexid reaction with dilute nitric acid or chlorin water.

707,813. TRIPHENYL-METHANE DYE AND PROCESS OF MAKING SAME. FRITZ ACH, Mannheim, Germany, assignor to The Firm of C. F. Boehringer & Soehne, Mannheim, Waldhof, Baden, Germany. Filed Dec. 23, 1900. Serial No. 40,702. (Specimens.)

Claim.—1. The process of preparing dyes which consists in oxidizing a mixture of an amido-phenyl-tartronic acid and an aromatic base.

2. The process of preparing dyes of the triphenyl-methane series which consists in heating the mixture of an amido-phenyl-tartronic acid with an aromatic base in the presence of an oxidizing agent.

3. The process of preparing dyes of the triphenyl-methane series which consists in heating the mixture of an amido-phenyl-tartronic acid with an aromatic base and hydrochloric acid in the presence of an oxidizing agent.

4. The process of preparing dyes which consists in heating the mixture of an amido-phenyl-tartronic acid with an aromatic base in the presence of a nitro compound, and a ferrous salt.

5. The process of preparing dyes of the triphenyl-methane series which consists in heating the mixture of an amido-phenyl-tartronic acid with an aromatic base and hydrochloric acid in the presence of a nitro compound, and a ferrous salt.

6. The process of preparing dyes of the triphenyl-methane series, which consists in oxidizing a mixture of an amido-phenyl-tartronic acid and a primary aromatic amin.

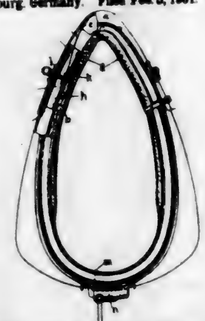
7. The process of preparing dyes of the triphenyl-methane series, which consists in heating an amido-phenyl-tartronic acid together with a primary aromatic amin and hydrochloric acid in the presence of a nitro compound, and a ferrous salt.

8. The process of preparing dyes which consists in heating an amido-phenyl-tartronic acid together with ethyl-benzyl-anilin and hydrochloric acid in the presence of an oxidizing agent.

9. The process of preparing dyes which consists in heating dimethyl-amido-phenyl-tartronate of potassium mixed with ethyl-benzyl-and hydrochloric acid, in the presence of nitrobenzene and ferric chlorid.

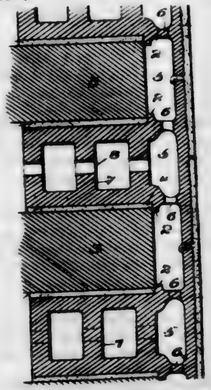
10. As a new dye compound, dimethyl-diethyl-dibenzyl-triamido-triphenyl-carbinol which has hitherto not been obtained in crystalline form, but tends to become resinous on exposure to air, is insoluble in water but readily soluble in alcohol is of a light-gray color but rapidly darkens in the air, and which when treated with feebly-fuming sulfuric acid at water-bath temperature yields a violet dyestuff.

707,814. COLLAR FOR HORSES OR THE LIKE. JOHANNES AHRENDT, Hamburg, Germany. Filed Feb. 5, 1901. Serial No. 46,086. (No model.)



Claim.—A collar comprising an upper portion to fit over the neck and having socketed lower ends, said upper portion consisting of an elastic upper piece bent to the form of an inverted U, a stiffened under neck-pad of similar shape, and a short middle piece between these bent parts, the lower portion of the collar having ends to fit the sockets of the upper portion, and means for adjusting and securing said ends in said sockets, substantially as described.

707,815. COMBINED BRICK AND TILE FOR WALLS &c. DAVID W. ANDERSON, Richmond, Va. Filed Jan. 23, 1902. Serial No. 90,947. (No model.)



Claim.—1. A combined brick and tile having a shoulder projecting from the body portion beyond the inner face of an intermediate brick

to serve as a guide for said intermediate brick, and to prevent the mortar from being pressed out from between the bricks.

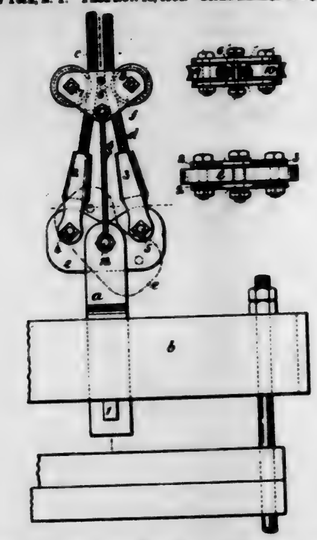
2. A combined brick and tile having a concavity in both the upper and lower edge of the tile portion to form a pocket for any excess of mortar.

3. A brick or tile having an enlarged edge and a concavity in both the upper and lower edge thereof to form pockets to contain the mortar keyage.

4. A combined brick and tile consisting of a hollow body portion, an extended tile surface, shoulders between the tile surface and the body portion, the edges of the tile portions having concavities or mortar-pockets.

5. A wall or similar structure composed of combined brick and tile having shoulders, intermediate bricks seated against the shoulders, extended tile surfaces on the combined brick and tile, and concave meeting edges on said extended surfaces, substantially as described.

707,816. EQUALIZER FOR CABLE-ROPES. WALTER H. BENNE, New York, N. Y. Filed Nov. 16, 1901. Serial No. 82,502. (No model.)



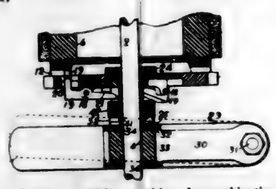
Claim.—1. The combination with the counterweight or car and two ropes or cables, of a device to which adjacent ends of said ropes or cables are pivotally connected, and a pivotal connection between said device and the counterweight or car, and means substantially as shown and described for holding the said ropes or cables above and adjacent to their point of connection in a predetermined relation to one another and at the same time permitting freedom of movement, substantially as set forth.

2. The combination with the cross-bar of an elevator-car or counterweight, the yoke connected therewith and ropes or cables, of a rocker-bar pivotally connected to the said yoke and devices at the respective ends of the ropes or cables for pivotally connecting the same to the rocker-bar at opposite sides of its pivotal connection to the yoke, and a frame of plates between which the ropes or cables pass, devices between and carried by said frame of plates and against which the cables bear to maintain the cables in a predetermined relation to one another, and means for connecting the said frame of plates to the aforesaid yoke, substantially as set forth.

3. The combination with the cross-bar of an elevator-car or counterweight, a yoke connected therewith, a pair of ropes or cables and rocker-heads connected to the ends of the ropes or cables and having strap prolongations with eyes, of a rocker-bar and a bolt for centrally and pivotally connecting the rocker-bar to the yoke and bolts for pivotally connecting the strap prolongations of the rocker-heads of the ropes or cables to the said rocker-bar at opposite points to its pivotal connection with the yoke, said rocker-bar having rounded corners and a central depression in said upper edge between the rounded corners, substantially as and for the purposes set forth.

4. The combination with a cross-bar of an elevator-car or counterweight and the yoke connected therewith, of a rocker-bar and a bolt for pivotally connecting the same centrally to said yoke, ropes or cables, rocker-heads connected to the ends of the ropes or cables and having prolongations with eyes, bolts for connecting the rocker-head prolongations to the rocker-bar adjacent to its ends, plates and bolts connecting the same and forming a frame between which said ropes or cables pass, grooved rollers pivotally mounted between said plates and against which the said ropes or cables bear, and bars extending from the said yoke to the said frame of plates connected at one end to the bolt of the yoke to which the rocker-bar is pivoted and at the other end to one of the securing-bolts of the frame of plates, substantially as and for the purposes set forth.

707,817. TYPE-WRITING MACHINE. ERNST M. ERNEST, Boston, Mass., assignor to Wyckoff, Seamans & Benedict, Ilion, N. Y., a Corporation of New York. Filed June 28, 1900. Serial No. 21,871. (No model.)



Claim.—1. In a type-writing machine, the combination with a cylindrical platen, of a fine-toothed wheel secured to the end thereof, a line-space wheel adjoining said fine-toothed wheel, and a detent extending through the line-space wheel to engage the said fine-toothed wheel.

2. In a type-writing machine, the combination with a cylindrical platen, of a fine-toothed wheel secured to the end thereof, a space-wheel adjoining said fine-toothed wheel, and a detent pivoted upon the opposite side of said line-space wheel and extending through the latter to engage the said fine-toothed wheel.

3. In a type-writing machine, the combination with a cylindrical platen, of a fine-toothed wheel secured to the end thereof, a line-space wheel adjoining said fine-toothed wheel, and a series of radially-arranged and independently spring-pressed detents pivoted upon the opposite side of said line-space wheel and extending through the latter to engage the said fine-toothed wheel.

4. In a type-writing machine, the combination with a cylindrical platen, of a fine-toothed wheel secured to the end thereof, a line-space wheel adjoining said fine-toothed wheel, a series of detents pivoted upon the opposite side of said line-space wheel and extending through the latter to engage said fine-toothed wheel, each of said detents having an arm, and a spring arranged between each of said arms and said line-space wheel.

5. In a type-writing machine, the combination with a cylindrical platen, of a fine-toothed wheel secured to the end thereof, a line-space wheel, cars fixed upon the latter, and a series of spring-pressed detents pivoted in said cars and engaging said fine-toothed wheel.

6. In a type-writing machine, the combination with a cylindrical platen, of a fine-toothed wheel secured to the end thereof, a platen-shaft, a line-space wheel loosely mounted upon said shaft, a movable detent engaging said fine-toothed wheel and mounted upon the line-space wheel, a collar supported upon the shaft and engaging said detent, and means for moving said collar along the said shaft to disengage the detent.

7. In a type-writing machine, the combination with a platen-frame and a cylindrical platen, of a fine-toothed wheel secured to the end thereof, a platen-shaft, a line-space wheel loosely mounted upon said shaft, a movable detent engaging said fine-toothed wheel and mounted upon the line-space wheel, and a lever mounted upon the platen-frame and connected to disengage said detent.

8. In a type-writing machine, the combination with a platen-frame and a cylindrical platen, of a fine-toothed wheel secured to the end thereof, a platen-shaft, a line-space wheel loosely mounted upon said shaft, a movable detent engaging said fine-toothed wheel and mounted upon the line-space wheel, a collar engaging said detent, and a lever mounted upon the platen-frame and constructed to move said collar along said shaft so as to disengage said detent.

9. In a type-writing machine, the combination with a cylindrical platen, of a fine-toothed wheel secured to the end thereof, a platen-shaft, a line-space wheel loosely mounted upon said shaft, a movable detent engaging said fine-toothed wheel and mounted upon the line-space wheel, a collar engaging said detent and supported upon said shaft, a platen-frame, a horizontally-swinging lever mounted upon said platen-frame, and an ear on said lever connected to said detent.

10. In a type-writing machine, the combination with a cylindrical platen, a fine-toothed wheel, a platen-shaft, a hand-wheel connected to turn said shaft, a line-space wheel, a detent, a platen-frame, and a lever

mounted upon the platen-frame and connected to move said detent to release the platen.

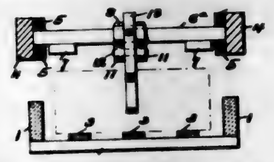
11. In a type-writing machine, the combination with a platen-frame, a cylindrical platen, and a line-space wheel, of a toothed wheel connected thereto, a releasable detent, a lever mounted upon the platen-frame, and connections between said lever and said detent.

12. In a type-writing machine, the combination with a platen and a line-space wheel, of an adjustment-wheel having teeth, and a series of detents connecting said wheels, said detents being so constructed and arranged as not to simultaneously fall between said teeth.

13. In a type-writing machine, the combination with a platen and a line-space wheel, of a wheel having evenly-spaced teeth, and releasable locking devices engaging said teeth and so constructed and arranged as to enable the platen to be adjusted relatively to the line-space wheel through finer intervals than the intervals between said teeth, and to be relocked to the line-space wheel at such finely-adjusted positions.

14. In a type-writing machine, the combination with a platen and a line-space wheel, of a spring-pressed releasable device for locking the platen to the line-space wheel, a lever or finger-piece operatively connected to said releasable device, whereby the latter may be moved to an inoperative position, and a frictional device for holding said lever and said releasable device during the adjustment of the platen relatively to the line-space wheel.

707,818. ICE-CARRIER. RICHARD BRADLEY, Branford, Conn. Filed Feb. 24, 1902. Serial No. 96,343. (No model.)



Claim.—1. The combination in an ice-carrier; of a frame; a dog-bracket fastened securely thereto and having a stop-lug thereon; and a dog pivotally secured to said bracket and so arranged as to engage said stop-lug whereby said dog is held against movement in one direction, all constructed and operating substantially as described.

2. The combination in an ice-carrier; of a carrier-frame comprising cross-pieces 6 6' and longitudinal tie-beams 7 7 connecting said cross-pieces; a dog-bracket 9 fixed to one of said cross-pieces; and a dog 13 pivotally secured within said bracket and depending below said frame, all constructed and operating substantially as shown and described.

707,819. POLISHING-MACHINE. JOHN W. BROWN, Jr., and HERBERT W. YEAGER, Philadelphia, Pa., assignors to The Enterprise Manufacturing Company of Pennsylvania, Philadelphia, Pa., a Corporation of Pennsylvania. Filed May 16, 1902. Serial No. 107,953. (No model.)

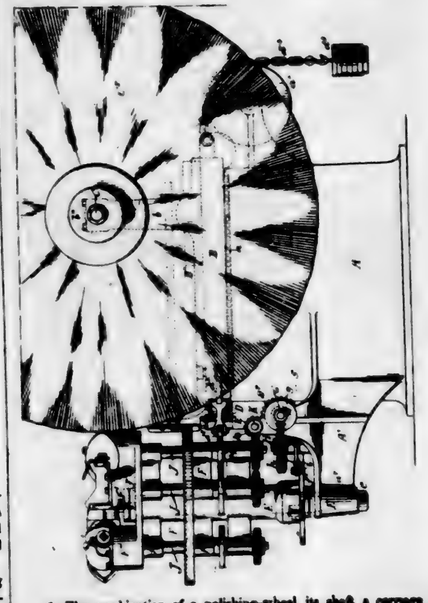
Claim.—1. The combination in a machine for polishing the edges of sad-irons and other objects, of a polishing-wheel, a carrier, a spindle mounted in bearings in the said carrier, means for turning the carrier, means for turning the spindle, a shaft geared to the spindle, and a chuck carried by said shaft for engaging the article to be polished, substantially as described.

2. The combination of a polishing-wheel, a standard, a carrier mounted on the standard, a series of spindles having their bearings in the carrier, a series of shafts arranged at right angles to the spindles and geared thereto, a chuck on each shaft for engaging a sad-iron or like object, a worm-wheel on each spindle, and a worm arranged to engage the spindles as they are brought into polishing position, with means for intermittently turning the carrier, substantially as described.

3. The combination in a polishing-machine, of a polishing-wheel, a carriage on which the shaft of the polishing-wheel is mounted, a standard, a carrier mounted on the standard, a spindle on the carrier, a shaft mounted on the carrier at an angle to the spindle and geared thereto, a chuck on the shaft for engaging a sad-iron or like object, a cam on the spindle, and a lever connected to the carriage and actuated by the cam for moving the carriage and its polishing-wheel toward and from the work carried by the chuck, substantially as described.

4. The combination in a polishing-machine, of a carriage, a polishing-wheel mounted on the carriage, a standard, a carrier on the standard, means for rotating the carrier, a series of shafts having chucks for engaging a sad-iron or like object to be polished, means for turning the shafts, and means for moving the polishing-wheel toward and from the work, substantially as described.

5. The combination in a polishing-machine, of a polishing-wheel, a carriage on which the wheel is mounted, a standard, a carrier mounted on the standard, means for intermittently rotating the carrier, a series of spindles having their bearings in the carrier, a shaft arranged at an angle above each spindle and geared thereto, a clutch for engaging a sad-iron or like object, means for releasing said clutch, and means for turning the spindles when the work is in position in respect to the polishing-wheel, substantially as described.



6. The combination of a polishing-wheel, its shaft, a carriage on which the shaft is mounted, a standard, a carrier mounted on the standard, a series of spindles having their bearings in the carrier, a cam on each spindle, and a lever actuated by the cams in rotation so as to move the polishing-wheel to and from the work, substantially as described.

7. The combination in a polishing-machine, of a polishing-wheel, a carrier, means for intermittently rotating the carrier, a series of spindles on the carrier, means for turning the spindles when in position, a series of heads secured to the carrier, a shaft on each head, each shaft being geared to a spindle, a chuck on the end of the shaft for engaging the sad-iron or other article to be polished, and a lever for actuating the chuck to release the iron, substantially as described.

8. The combination in a polishing-machine, of a base, a carriage, a driven shaft, a polishing-wheel mounted on said shaft, a bracket projecting from the base, a standard secured to the bracket, a carrier mounted on the standard, a driven shaft, a star-wheel gear by which the carrier is driven from the said shaft, a series of spindles on the carrier, a hand above each spindle, a shaft in said head and geared to the spindles, chucks on the shafts for the reception of the article to be polished, a cam on each spindle, and connecting means by which the cams operate the carriage on which the polishing-wheel is mounted, substantially as described.

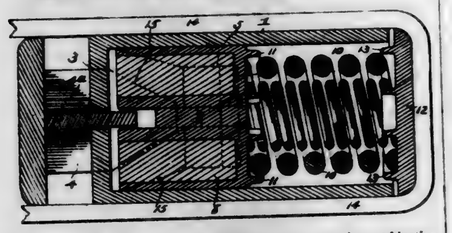
9. The combination in a polishing-machine, of the base, a polishing-wheel, a bracket, a standard on the bracket, a carrier mounted on the standard, a star-wheel secured to the carrier, a driven shaft, a worm on said shaft, a worm-wheel on the standard, a disk connected to the worm-wheel and having a pin which enters the slots in the star-wheel and through which the carrier is given an intermittent rotary motion, a series of slots on the carrier, a shaft in each head, a chuck on the shaft for engaging the article to be polished, and means for rotating one of the shafts when the iron is in line with the polishing-wheel, substantially as described.

10. The combination in a polishing-machine, of the base, a polishing-wheel, a standard, a carrier mounted on the standard, a driven shaft, a worm, worm-wheel, and a star-gear in one of said driving-shafts, a carrier by which an intermittent rotary motion is given to the carrier, a series of slots on the carrier, a shaft in each head, a chuck mounted in each shaft for engaging the article to be polished, a series of spindles having their bearings in the carrier and geared to the said chuck-shaft, a

worm-wheel on each spindle, a driven shaft, and a worm thereon engaging one of the worm-wheels when the article to be polished is brought in line with the polishing-wheel, substantially as described.

11. The combination in a polishing-machine, of the base, a carriage, a weight for moving the carriage away from the work, a standard, a carrier mounted on the standard, means for intermittently rotating the carrier, a series of spindles, a shaft-shaft geared to each spindle, means for rotating the spindle, a cam on each spindle, a lever pivoted to the frame of the machine having one arm resting against the cam of the spindle in line with the rotating spindles, the other end of the said lever being connected to the carriage so as to move the polishing-wheel toward and from the work as the work is turned, substantially as described.

707,820. **FRICTION DRAW-GEAR AND BUFFING APPARATUS FOR RAILROAD-CARS.** SAMUEL P. BUSH, Columbus, Ohio, assignor to the Buckeye Malleable Iron and Coupler Co., Columbus, Ohio. Filed Mar. 22, 1902. Serial No. 99,461. (No model.)



Claim.—1. In a draw-gear and buffing apparatus, the combination with opposing wedges mounted to move simultaneously in the same direction, a resisting-spring behind one of said wedges and a transversely-movable device interposed between said wedges.

2. In a draw-gear and buffing apparatus, the combination with opposing wedges in line with each other in a plane coincident with that of the draft devices, said wedges mounted to move together in the same direction, a resisting-spring behind one of said wedges and a transversely-movable device interposed between said wedges.

3. In a draw-gear and buffing apparatus, the combination with opposing wedges arranged in line with each other and mounted to move simultaneously in the same direction, and a resisting-spring behind one of said wedges, of a transversely-movable part interposed between said opposing wedges, and means for preventing longitudinal movement of said transversely-disposed device, in a direction parallel with the movement of the wedges.

4. In a draw-gear and buffing apparatus, the combination with a casing having shoulders or abutments separated from each other, of opposing wedges movable in unison in the same direction in said casing, intermediate transversely-movable devices separating said wedges and located within the casing between said shoulders or abutments, and a spring bearing against one of said wedges.

5. In a draw-gear and buffing apparatus, the combination of opposite wedges movable together in the same direction, a transversely-movable part intermediate of and separating said wedges, a resisting-spring, and a case to hold the parts.

6. In a draw-gear and buffing apparatus, the combination of opposing wedges movable together in the same direction, an intermediate transversely-movable part disposed between and separating said wedges and against which the wedges bear, a spring in line with the wedges, a case to hold the parts, and a follower-plate against which the spring bears.

7. In a draw-gear and buffing apparatus, the combination of a follower-plate having a wedge-shape projection, an opposite wedge in line with the first wedge, an intermediate transversely-movable part separating said wedges and against which the wedges bear from opposite sides, and a resisting-spring in line with the wedges.

8. In a draw-gear and buffing apparatus, the combination of a wedge in positive contact with the draw-bar, an opposite wedge in the same line and having a seat to receive one end of a spring, and an intermediate transversely-movable part separating said wedges and against which the wedges bear from opposite sides.

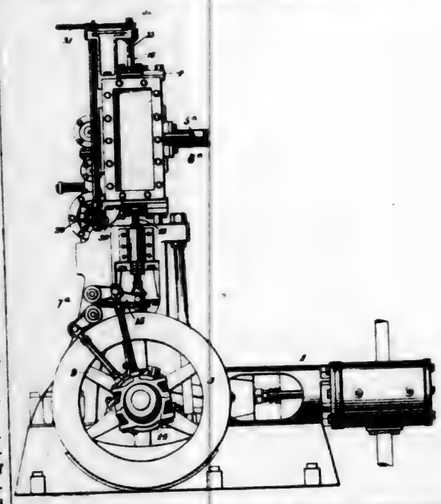
9. In a draw-gear and buffing apparatus, the combination of opposite wedges that move together in the same direction, and an intermediate transversely-movable part that is forced laterally positively in one direction as the wedges move forward and laterally in the opposite direction as the wedges are moved back.

10. In a draw-gear and buffing apparatus, the combination of opposite wedges in line with the draw-bar, an intermediate transversely-movable part separating said wedges and against which the wedges bear from opposite sides, a spring in line with the wedges and holding the latter in contact with the transversely-movable part, and a case to hold the parts.

11. In a draw-gear and buffing apparatus, the combination of opposite wedges that move together in the same direction, an intermediate transversely-movable part separating said wedges, a follower-plate, a spring, one end of which bears against a wedge and the other against the follower-plate, and a case to hold the parts.

12. In a draw-gear and buffing apparatus the combination with two followers restrained against outward movement, of a sliding casing intermediate the followers, opposite wedges that move in unison in the same direction in buffing, an intermediate transversely-movable part separating said wedges, and a spring.

707,821. **AIR-PUMP.** THEODORE N. CASE, Mount Vernon, N. Y. Filed Dec. 4, 1901. Serial No. 84,598. (No model.)



Claim.—1. In an air-pump the combination of a pumping-cylinder, a pumping-piston therein, a governor air-chamber, a connection between said pumping-cylinder and said governor air-chamber and positively-actuated means for opening said connection just prior to the opening of the pumping-cylinder discharge-ports and maintaining it closed at all other times, said means being independent of said pumping-piston.

2. In an air-pump the combination of a pumping-cylinder, a pumping-piston therein, a governor air-chamber, a connection between the extreme end of said pumping-cylinder and said governor air-chamber and positively-actuated means for opening said connection just prior to the opening of the discharge-ports of said pumping-cylinder and maintaining it closed at all other times.

3. In an air-pump the combination of a pumping-cylinder, a pumping-piston therein, and main and release valves therefor, a governor air-chamber having a piston therein, one end of said governor air-chamber being connected to the pumping-cylinder and the other subjected to receiver-pressure, means actuated by said governor-air-chamber piston for adjusting said release-valves and positively-actuated means for opening said connection just prior to the opening of the discharge-ports of said pumping-cylinder and maintaining it closed at all other times, said means being independent of said pumping-piston.

4. In an air-pump the combination of a pumping-cylinder, a piston therein, a positively-actuated main discharge-valve, a positively and independently actuated release-valve, a governor for determining the action of said release-valve, a governor air-chamber, a piston therein, a connection between one end of said air-chamber and both ends of said pumping-cylinder, and positively-actuated means for opening the connection with the pumping-cylinder just prior to every discharge of the pumping-cylinder and maintaining it closed at all other times.

5. In an air-pump the combination of a pumping-cylinder, a piston therein, a positively-actuated main valve, a positively-actuated release-valve, and means controlled by the pressure in said cylinder for automatically adjusting said release-valve relatively to said main valve

6. In an air-pump the combination of a pumping-cylinder, a piston therein, a positively-actuated main valve, a positively and independently actuated release-valve, an air-controlled governor for adjusting said release-valve and pressure-ports connecting said pumping-cylinder with said governor and controlled by said release valve.

7. In an air-pump the combination of a pumping-cylinder, a piston therein, a positively-actuated main valve, a positively and independently actuated release-valve, a fluid-cylinder containing a piston for adjusting said release-valve, an air-chamber and piston controlling said fluid-cylinder, and a connection between said air-cylinder and said pumping-cylinder controlled by said release-valve.

8. In an air-pump the combination of a positively-actuated main valve, a positively-actuated release-valve movable relatively thereto, a governor for automatically adjusting said release-valve and means controlled by the positions of said main and release valves for actuating said governor.

9. In an air-pump the combination of a main valve, a release-valve, a governor for automatically adjusting said release-valve relatively to said main valve, and air-ports leading to said governor which are controlled by the positions of said main and release valves.

10. In an air-pump the combination of an air-cylinder, a piston therein, a main valve, a positively-actuated release-valve, movable relatively thereto, a governor for automatically adjusting said release-valve relatively to said main valve, said governor being controlled by air-pressure exerted through ports controlled by said release-valve.

11. In an air-pump the combination of a cylinder, a main valve, a positively-actuated release-valve, a rod for actuating said release-valve, means for adjusting said valve by the rotation of said rod and a governor for automatically rotating said rod.

12. In an air-pump the combination of a main valve and a release-valve movable relatively thereto, a rod for adjusting said release-valve by its rotary movement and means for automatically rotating said rod in either direction controlled by the positions of said main and release valves.

13. In an air-pump, a governor consisting of an air-cylinder and piston therein, a revolvable screw-threaded nut actuated by said piston, a rod moved therein, a fluid-valve actuated by said rod controlling the entrance and egress of said fluid-pressure in and to the operating-cylinder of the governor.

14. In an air-pump the combination of the cylinder, a piston therein, a main valve, a positively-actuated release-valve consisting of two members, a rod for actuating said members and also adjusting their relative positions.

15. In an air-pump the combination of a cylinder, a piston therein, a main valve, a positively-actuated release-valve consisting of two members, a rod for actuating said members by its longitudinal movement and adjusting their relative positions by its axial rotation.

16. In an air-pump a governor for adjusting a release-valve having a fluid-operating cylinder, a piston therein, a fluid-valve controlling the ports to said cylinder, a movable rod for actuating said valve through a lever connected by a link to the rod of the piston in the operating-cylinder and to said valve.

17. In an air-pump the combination of a cylinder, a reciprocating piston therein, a positively-actuated main valve, a positively-actuated release-valve, a positively-actuated equalizing-valve establishing a connection between the two ends of the cylinder when the main-valve ports are out of register with the cylinder-ports.

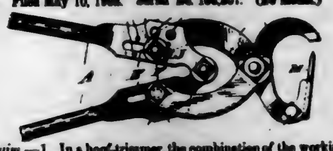
18. In an air-pump the combination of a cylinder, a piston therein, a main valve, a release-valve having a chamber connected with a low-pressure source and acting to hold said valve to its seat.

19. In an air-pump the combination of a cylinder, a piston therein, a main valve, a release-valve having a chamber connected with the suction-chamber of said pump and acting to hold said valve to its seat.

20. In an air-pump, the combination of the cylinder 4, a piston 4*, the main valve 7, the release-valve 12 and equalizing-valve 37, and means for actuating the same.

21. In an air-pump the combination of the cylinder 4, the piston 4*, a main valve 7, a release-valve 12, a governor therefor having an air-chamber and an air-passage leading thereto controlled by the positions of said valve 12 and said main valve 7.

707,822. **HOOF-TRIMMER.** WARREN S. CASTERLIN, Pittston, Pa. Filed May 10, 1902. Serial No. 106,827. (No model.)



Claim.—1. In a hoof-trimmer, the combination of the working members pivoted together, the lever members pivoted together and provided with longitudinal slots, and pivot-bolts inserted through the ends of the working members and the said slots of the lever members.

2. In a hoof-trimmer, the combination of the working members pivoted together, the lever members pivoted together and having lateral offsets provided with a series of transverse openings and also having longitudinal slots between said transverse openings and their inner edges, and pivot-bolts adapted to be inserted through the ends of the working members and the said slots or the said transverse openings.

3. In a hoof-trimmer, the combination of the working members pivoted together, the lever members pivoted together and having longitudinal slots and notches or recesses adjacent to the edges of the said slots, pivot-bolts inserted through the ends of the working members and through the said slots, washers fitted on the said bolts and provided with lugs adapted to engage the said notches or recesses, and retaining-nuts on the bolts adapted to be turned against the said washers whereby the pivot-bolts may be permitted to move along said slots or held against such movement at will.

4. In a hoof-trimmer, the combination of the lever members, the working members pivoted to the lever members and to each other, one of the working members having its end centrally divided and provided with a dovetailed groove in its outer face, a knife fitted in said groove and having teeth on its edges adapted to take into the walls of the same, and a clamping-bolt inserted transversely through the member to secure the knife.

707,828. **METHOD OF DRYING COLLARS.** ROBERT CLOTT, Troy, N. Y., assignor to Clott, Peabody & Co., Troy, N. Y., a Corporation. Filed Mar. 31, 1902. Serial No. 100,733. (No model.)

Claim.—1. That improvement in the art of drying, preparatory to ironing, previously-starched collars, and like articles, each having buttonholes arranged to be a predetermined distance apart, which consists in arranging each of such articles with the buttonholes thereof fixed at said predetermined distance apart, and then drying the article and at the same time maintaining the buttonholes thereof in said fixed relation to each other, until the article is dried, substantially as described.

2. That improvement in the art of drying, preparatory to ironing previously-starched collars and like articles having buttonholes arranged at a predetermined distance apart, which consists in suspending the article while wet upon supports inserted through said buttonholes and spaced a distance apart equal to the predetermined distance apart of the buttonholes and drying the article while so suspended.

3. That improvement in the art of drying, preparatory to ironing, previously-starched collars and like articles having end buttonholes arranged at a predetermined distance apart which consists in suspending the article while wet upon supports inserted through said buttonholes and

spaced to equal the predetermined distance apart of the buttonholes and located substantially in the same horizontal plane, whereby the extremities below the supports are caused to gravitate to a relatively uniform shape and position and drying the article while so suspended.

707,824. CLOTHES-HOOK. ALPHEUS H. COBB, Asheville, N. C. Filed Jan. 14, 1902. Serial No. 89,761. (No model.)

Claim.—1. A hook comprising a single piece of wire bent to the desired form, and provided with a fastening device formed by one end of the wire being bent rearwardly and doubled back upon itself and secured, said doubled extension being sharpened at its looped end.

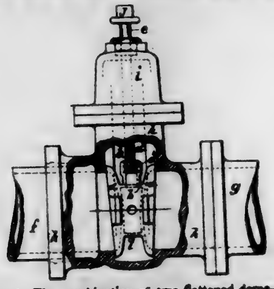
2. A hook comprising a single piece of wire bent to the desired form and provided with a fastening device comprising a reinforced looped extension formed by one end of said wire being bent upwardly and rearwardly and doubled back upon itself and secured, said reinforced extension being sharpened at its looped end.

3. A hook of the character described, composed of one piece of wire having a body portion comprising the upper and lower hooks, a downwardly-projecting looped extension carried by the hook, formed by the wire being bent upon itself and secured to the body portion of the hook, and a chisel-point formed upon the end of said looped extension.

4. A device of the character described comprising a single piece of wire bent to form a plurality of hooks forming the body portion of the device, and a fastening extension formed by one end of the wire being bent rearwardly at an angle to said body portion and doubled back upon itself and secured to the body portion, said extension being sharpened at its looped end.

5. A device of the character described comprising a single piece of wire bent to form a plurality of hooks and a plurality of rearwardly-projecting looped extensions, said extensions being sharpened at their looped ends and adapted to be driven into a support.

707,825. WATER-GATE. DAVID M. B. COFFIN, Newton, Mass., assignor to Coffin Valve Company, Boston, Mass., a Corporation of Massachusetts. Filed Oct. 19, 1901. Serial No. 79,213. (No model.)



Claim.—1. The combination of two flattened-dome-shaped valve-disks having seat-faces in relatively angular relation to each other and the annular union or ring connection uniting them, said union being concentrically arranged in relation to the valve-faces or bases of resistance and to the valve-center, substantially as shown and described.

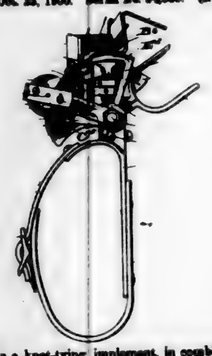
2. In a gate for water and other fluids, having double or twin valve-seats, the two spring valve-disks having seat-faces at their periphery and an annular union or connection concentrically connecting said disks and seat-faces substantially as shown and described.

3. In a water-gate, or gate for any fluid, having two relatively angular-faced valve-seats, a valve constructed with two spring valve-disks having faces corresponding to the seat-faces and an annular union or connection arranged midway from center to seat-faces and concentrically to the seats connecting them together, substantially as shown and described.

4. In a gate for water or other fluids having twin valve-seats between which is forced a taper valve for closing and from between which the valve is withdrawn for opening, by a valve-stem, the two spring valve-disks united together by an annular connection arranged midway between center and seats and concentrically in relation to both center and seat-faces, substantially as shown and described.

5. The twin disks constructed each with its own attached part of the annular union separate from the other and having within the circle of the union a web or plate *c* joined to each such separate part of the union by which it may be bolted to the other part, and bolt-holes and the bolts *d* bolting them together and so completing the union, substantially as shown and described.

707,826. KNOT-TYING IMPLEMENT. HOWARD D. COLMAN, Rockford, Ill. Filed Oct. 23, 1900. Serial No. 34,099. (No model.)



Claim.—1. In a knot-tying implement, in combination, means for forming a loop in a thread; which means comprises a rotatable winding-spindle; means for passing a bight of said thread through said loop; and means for introducing a second thread into said bight.

2. In a knot-tying implement, in combination, means for forming a loop in a thread; which means comprises a rotatable winding-spindle; means for passing a bight of said thread through said loop; and means for holding a second thread in such position that the bight thus formed may be pulled over said second thread.

3. In a knot-tying implement, in combination, means for looping a thread in helical form; which means comprises a rotatable winding-spindle and a movable thread-guide; means for passing a bight from one of the windings of the helix inwardly through the central loop of the latter; and means for introducing a second thread into said bight.

4. In a knot-tying implement, in combination, mechanism for forming a loop in a thread; which mechanism comprises a rotatable bifurcated winding-spindle; means for passing a bight of the thread through the formed loop; and means for introducing a second thread into said bight.

5. In a knot-tying implement, in combination, a winding-spindle for forming a loop in a thread; a shearing and clamping jaw pivotally mounted on said spindle; means for passing a bight of said thread through the formed loop; and means for introducing a second thread into said bight.

6. In a knot-tying implement, in combination, a winding-spindle having an opening therein; a shearing and clamping jaw pivotally mounted on said spindle; means for rotating said spindle and winding a thread thereon; means adapted to pass through the opening in said spindle, for passing a bight of said thread through the loop formed by winding it about said spindle; and means for holding a second thread in such position that the bight thus formed may be pulled over said second thread.

7. In a knot-tying implement, in combination, a winding-spindle having an opening therein, also having a shearing and clamping jaw; means for rotating said spindle and winding a thread thereon; means adapted to pass through the opening in said spindle, for passing a bight of said thread through the loop formed by winding said thread about the spindle; and a shearing and clamping jaw for holding a second thread in such position that the bight thus formed may be pulled over said second thread.

8. In a knot-tying implement, in combination, means for forming a loop in a thread; which means comprises a rotatable winding-spindle having a shearing and clamping jaw; a finger adapted to pass a bight of said thread through said loop; and means for introducing a second thread into said bight.

9. In a knot-tying implement, in combination, means for forming a loop in a thread, said means comprising a shearing and clamping jaw; a tumbler-finger adapted to pass a bight of said thread through said loop; and means for introducing a second thread into said bight.

10. In a knot-tying implement, in combination, means for forming a loop in a thread, said means comprising a shearing and clamping jaw; a tumbler-finger adapted to pass a bight of said thread through said loop; and means for holding a second thread in such position that the bight thus formed may be pulled over said second thread.

11. In a knot-tying implement, in combination, means for forming a loop in a thread, said means comprising a shearing and clamping jaw; a tumbler-finger adapted to pass a bight of said thread through said loop and a clamping-jaw for holding a second thread in such position that the bight thus formed may be pulled over said second thread.

12. In a knot-tying implement, in combination, means for forming a loop in a thread; a tumbler-finger adapted to pass a bight of said thread through said loop; and a shearing and clamping jaw on said tumbler-finger, for cutting off a second thread, and for holding it in such position that said bight may be pulled over said second thread.

13. In a knot-tying implement, in combination, a winding-spindle having an opening therein; means for rotating said winding-spindle; a tumbler-finger adapted to pass through the opening in said winding-spindle; means for turning said tumbler-finger; and means for holding a second thread adjacent to said winding-spindle.

14. In a knot-tying implement, in combination, a winding-spindle having an opening therein; a shearing and clamping jaw on said spindle; means for rotating said spindle; a tumbler-finger adapted to pass through the opening in said spindle; means for turning said tumbler-finger; and a shearing and clamping jaw on said finger.

15. In a knot-tying implement, in combination, a winding-spindle having an opening therein; a shearing and clamping jaw on said spindle; a thread-guide adapted to have a longitudinal movement with relation to said spindle while the same is being rotated; a tumbler-finger adapted to pass through the opening in said spindle; means for turning said tumbler-finger; and a shearing and clamping jaw on said tumbler-finger.

16. In a knot-tying implement, in combination, a winding-spindle having an opening therein; a shearing and clamping jaw on said spindle; a thread-guide adapted to have a longitudinal movement with relation to said spindle during the rotation of the latter; a tension-arm; a tumbler-finger adapted to pass through the opening in said spindle; a gear for turning said tumbler-finger; and a shearing and clamping jaw on said finger.

17. In a knot-tying implement, in combination, a winding-spindle having an opening therein; a shearing and clamping jaw on said spindle; intermeshing gear for rotating said spindle; said spindle also having a cam-groove; a thread-guide adapted to be actuated by said grooved cam; a tension-arm; a cam for actuating said tension-arm; a tumbler-finger adapted to pass through said opening in said spindle; a gear for turning said tumbler-finger; and a shearing and clamping jaw on said finger.

18. In a knot-tying implement, in combination, a winding-spindle having an opening therein, and a cam-groove; a shearing and clamping jaw on said spindle; a pinion and a delay-shoe for the spindle; a sector-gear; gear-teeth and two delay-fingers on said sector; a thread-guide adapted to be actuated by said grooved cam; a tumbler-finger adapted to pass through the opening in said spindle; means for turning said tumbler-finger; and a shearing and clamping jaw on said finger.

19. In a knot-tying implement, in combination, a winding-spindle having an opening therein; a shearing and clamping jaw on said spindle; said spindle also having a pinion and a delay-shoe thereon, and a cam-groove therein; a guide-arm for the thread, adapted to be moved by said grooved cam; a sector-gear having gear-teeth for said pinion, and two delay-fingers for said delay-shoe; a tension-arm; a cam for actuating said tension-arm; a thumb-lever for moving said sector and said cam; a projection on the sector-gear for opening and closing the shearing and clamping jaw; a tumbler-finger adapted to pass through the opening in said spindle; means for turning said tumbler-finger; and a shearing and clamping jaw on said finger.

20. In a knot-tying implement, in combination, a winding-spindle having an opening therein and a cam-groove; said spindle also having a pinion, a delay-shoe, and a shearing and clamping jaw; a fixed guide for holding said shearing and clamping jaw closed; a sector-gear having gear-teeth for said pinion and two delay-fingers for said delay-shoe, also having a projection for opening and closing said shearing and clamping jaw; a shaft for said sector-gear; a sector-cam loosely mounted on said shaft, but movably connected with said gear-sector; a tension-arm adapted to be actuated by said sector-cam; a thread-guide adapted to be moved by the grooved cam of said winding-spindle; a thumb-lever having a rigid connection with said cam-sector; a tumbler-finger adapted to pass through the opening in said spindle; means for turning said tumbler-finger; and a shearing and clamping jaw on said finger.

21. In a knot-tying implement, in combination, a winding-spindle having an opening therein; means for rotating said spindle; a tumbler-finger adapted to pass through the opening in said spindle; a supporting-shaft for said tumbler-finger; a pinion and a delay-shoe on said shaft; a fixed sector having gear-teeth for said pinion, and a peripheral delay-surface for said delay-shoe; and a shearing and clamping jaw for said tumbler-finger.

22. In a knot-tying implement, in combination, a winding-spindle having an opening therein; means for rotating said spindle; a shaft; a thumb-lever on said shaft; an arm fixed with relation to said shaft; a frame on said arm; a tumbler-finger adapted to pass through the opening in said spindle; a shaft for said tumbler-finger; said frame being provided with a channel concentric with the bearing for said tumbler-finger, said channel having a pocket near its end; a pinion and a delay-shoe on said tumbler-finger shaft; a fixed sector having gear-teeth for said pinion and a peripheral delay-surface for said delay-shoe; a shearing and clamping jaw having a pivotal connection with said tumbler-finger, also having an integral arm; a stud on said arm, adapted to engage the concentric channel in said frame; and a pivotal engagement between said tumbler-finger and said arm, whereby the stud on said arm is thrown into the pocket in said channel to open said shearing and clamping jaw.

707,827. EYEGLASS-GUARD. JAMES F. COOMBS, Chicago, Ill., assignor of one-fourth to Frederick Kendall Lawrence, Chicago, Ill. Filed June 8, 1901. Serial No. 63,662. (No model.)

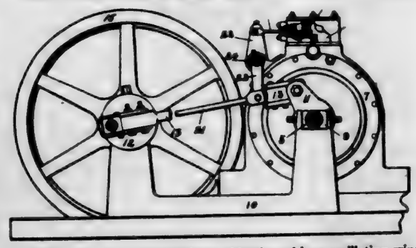
Claim.—1. The combination in an eyeglass, of an attaching-stud formed with a screw-threaded orifice and projecting flanges at opposite sides of said orifice, which flanges have open-top recesses that extend at right angles to the axis of said orifice, a guard-piece formed with an orifice alining with the orifice of the attaching-stud and with lateral lugs to engage said open-top recesses, and an attaching-screw engaging in said orifices to hold the parts in place, substantially as set forth.

2. The combination in an eyeglass, of an attaching-stud formed with a screw-threaded orifice and projecting flanges at opposite sides of said orifice, which flanges have open-top recesses that extend at right angles to the axis of said orifice, a guard-piece formed with an orifice alining with the orifice of the attaching-stud and with lateral lugs to engage said open-top recesses, the said lugs having angular extensions adapted to fit outside the flanges of the attaching-stud, and an attaching-screw engaging in said orifices to hold the parts in place, substantially as set forth.

3. The combination in an eyeglass, of an attaching-stud, a guard of ductile material comprising a flat reduced extension which extends downwardly in an oblique direction toward an adjacent lens, a loop portion at the lower end of such oblique portion and located between the same and the adjacent lens and a rearwardly and upwardly extended portion of said loop portion carrying at its free end a nose-pad, and means for attaching the guard to the stud, substantially as herein described.

4. The combination in an eyeglass, of a pair of attaching-studs, an integrally-formed guard of ductile material comprising a middle spring-bow portion, a pair of flat reduced extensions which extend downwardly in oblique directions toward the respective lens, loop portions at the lower ends of such oblique portions and located between the same and the adjacent lens and rearwardly and upwardly extended portions of said loop portions carrying at their free ends the nose-pads, and means for attaching the guard to the studs, substantially as herein described.

707,828. ENGINE. WILLIAM G. COWAN and ALONZO JEWETT, Saginaw, and JOHN G. WARDELL, East Tawas, Mich. Filed Mar. 6, 1902. Serial No. 96,972. (No model.)

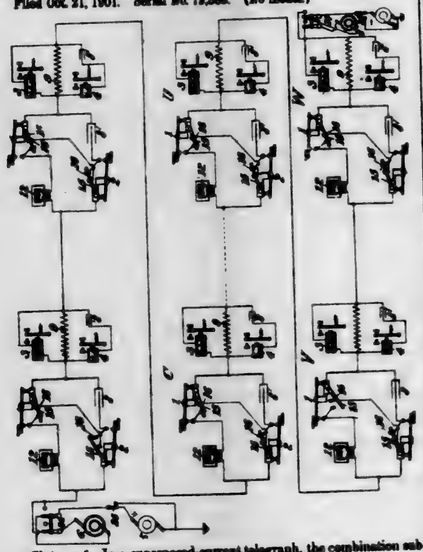


Claim.—1. In an engine the combination with an oscillating wing-piston, a valve-chest, ports connecting the valve-chest with the piston-chamber and a slide-valve for controlling the flow through said ports; of a trunnion having a pair of by-pass ports, each arranged to connect the

steam-spaces on opposite sides of a wing when the wing is near the bottom of its stroke; an exhaust-port in said trunnion, arranged to discharge steam from the space underneath the wing when the wing is near the top of its stroke; and an exhaust-passage in the engine-cylinder, arranged to register with the exhaust-port of the trunnion when the wing is near the top of its stroke, substantially as described and for the purposes set forth.

2. In an engine the combination of an oscillating trunnion mounted within the engine-cylinder and carrying diametrically opposite wings; ports for admitting and discharging steam from the spaces above said wings; a slide-valve for controlling said ports; a pair of by-pass ports formed in the trunnion, each port being arranged to connect the steam-spaces on opposite sides of a wing when the wing is near the bottom of its stroke; an exhaust-port in the lower side of the trunnion, arranged to discharge steam from the space underneath the wing when the wing is near the top of its stroke; an exhaust-passage in the engine-cylinder, arranged to register with the exhaust-port of the trunnion when the wing is near the top of its stroke; an oscillating arm secured to said trunnion and arranged to actuate a rotating shaft, together with means operated by said shaft for actuating the slide-valve.

707,829. **TELEGRAPHY.** ALBERT C. CREHORE, Tarrytown, N. Y. Filed Oct. 21, 1901. Serial No. 79,353. (No model.)



Claim.—1. In a superposed-current telegraph, the combination substantially as described with continuous and pulsatory current receivers arranged in shunt relation to one another and having a condenser in the pulsatory-current branch, of transmitters for the two sides of the system arranged in shunt relation to one another, an inductance in the branch with the continuous-current transmitter, and a condenser in the branch with the pulsatory-current transmitter, said transmitter branches being independent of those containing the receivers.

2. In a superposed current telegraph, the combination of transmitters for the pulsatory and continuous sides of the system respectively, arranged in shunt relation to one another, and an inductance in the shunt or branch containing the continuous-current transmitter whereby when the latter transmitter is closed the transmitter in the other branch opens and closes a shunt around the branch which offers an impedance to the flow of the pulsatory current.

3. In a superposed-current telegraph, a single main line having transmitting apparatus for the continuous and pulsatory sides of the system respectively, arranged in shunt relation to one another, in combination with an inductance in the shunt containing the continuous-current transmitter and a condenser in the shunt containing the pulsatory-current transmitter.

4. In a superposed-current system of telegraphy, the combination with the continuous-current and pulsatory-current transmitters at a station, of means for short-circuiting the transmitting apparatus for the pulsatory-current and continuous-current sides of the system respectively, said short-circuiting devices being connected in series as described so that neither shall be effective to short-circuit until both are thrown to short-circuiting position.

5. In a superposed-current telegraph, the combination substantially as described, of a continuous-current transmitter and a pulsatory-current transmitter placed in shunt relation to one another upon the same circuit but both in series relation to the portion of circuit containing the receivers said transmitter branches or shunts containing respectively a condenser and an inductance as and for the purpose described.

6. In a superposed-current telegraph, two branches of the line-circuit in shunt relation to one another, one containing a Morse key and inductance, and the other a condenser and Morse key, said keys being arranged at opposite ends of the branches respectively, with their short-circuiting switches connected direct to line, and supplemental contacts for said switches connected together as and for the purpose described.

7. In a superposed-current telegraph, the combination substantially as described of a transmitter for the continuous-current side of the system and an inductance arranged in one shunt or branch of the circuit, a transmitter for the pulsatory-current side of the system and a condenser arranged in another branch which is in shunt relation to the first-named branch said transmitters being placed at opposite ends of their shunts or branches respectively, a switch for each transmitter whereby it may be short-circuited without short-circuiting the reactance or condenser as the case may be, and supplemental contacts for said switches connected as described so that only when both switches are closed both the inductance and condenser will be short-circuited.

8. In a superposed-current system of telegraphy, the combination substantially as described, with suitable continuous-current and pulsatory-current receivers, of continuous-current and pulsatory-current transmitters, a condenser in a shunt to a branch containing the continuous-current transmitter and an inductance in a shunt to the branch containing the pulsatory-current transmitter, said transmitter branches being independent of those branches or parts of the circuit in which the said receivers are located.

9. In a superposed-current telegraph, transmitters for the continuous-current and pulsatory-current sides of the system respectively, arranged in shunt relation to one another and each adapted to make and break the shunt in which it is placed, in combination with an inductance in the shunt containing the continuous current transmitter and a condenser in the shunt containing the pulsatory-current transmitter.

10. In a superposed-current telegraph, the combination of a pulsatory-current generator, a continuous-current generator, transmitting-keys adapted to make and break circuit and normally short-circuited, a condenser, a reactance and means for introducing the keys into circuit, one in a condenser-shunt around the reactance and the other in a shunt around a condenser.

11. In a superposed-current system of telegraphy, the combination with way-station receiving apparatus comprising a continuous-current receiver in shunt to a condenser and the pulsatory-current receiving apparatus while the apparatus is in the condition for receiving, of transmitters for the two sides of the system both normally short-circuited, branches or shunts of the circuit, one a condenser shunt or branch around a reactance, and the other an inductance shunt or branch around a condenser, and means for including said transmitters respectively in the branches.

12. The combination with the continuous and pulsatory current transmitters in shunt relation to one another, of a reactance, a condenser, and two interdependent circuit-closing devices, one for each key, co-operating as described to short-circuit the condenser and reactance.

13. In a superposed-current system of telegraphy, the combination with two branches of the circuit one containing an inductance and transmitter, and the other containing a condenser and transmitter, of a short-circuiting device for each branch, one adapted to shunt the inductance and the other to shunt the condenser said short-circuiting devices being connected in series as described.

14. In a superposed current system of telegraphy, two branches of line-circuit in shunt relation to one another, one containing an inductance and Morse key, the other a condenser and Morse key combined with key-switches having supplemental contacts, and a connection between said contacts forming a short circuit for both the inductance and the condenser, as and for the purpose described.

15. In a superposed-current telegraph, the combination of transmitting apparatus for the pulsatory-current side of the system, an inductance-shunt therefor, transmitting apparatus for the continuous-current side of the system, a condenser-shunt therefor and circuit-closing devices for said transmitting apparatus adapted to form a short circuit around both the inductance and the condenser when said transmitting apparatus is out of use.

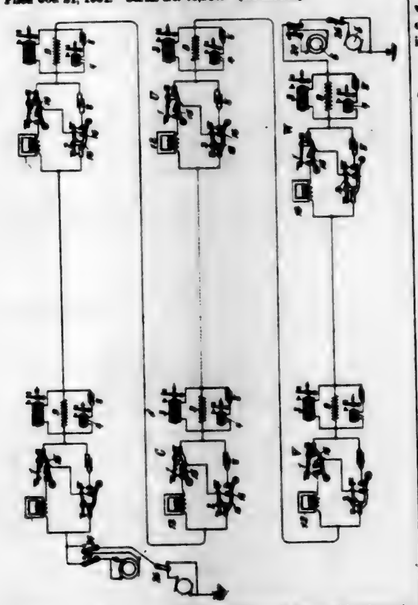
16. In a superposed-current telegraph, the combination of a continuous-current receiver, a pulsatory-current receiver, a condenser, an inductance, continuous-current transmitting apparatus in a branch of the circuit independent of the continuous-current receiver and forming a shunt to the condenser, pulsatory-current-transmitting apparatus in a branch of the circuit independent of the pulsatory-current receiver and forming a shunt to the inductance, and circuit-closing devices adapted to short-circuit both said inductance and condenser when either transmitting apparatus is not in use.

17. In a superposed-current telegraph, the combination of an inductance, a pulsatory-current transmitter adapted to transmit signals by opening and closing a branch of the main line around said inductance, a condenser in the branch with the pulsatory-current transmitter, a continuous-current transmitter adapted to open and close a branch of the main line around said condenser, and circuit-closing devices for shunting either the condenser or inductance out of the line-circuit when either transmitter is not in use.

18. In a superposed-current telegraph, the combination with a pulsatory-current generator and a Morse key controlling the connection of said generator with the line of a circuit-closer for said key, and a contact therefor connected to a branch leading from the key to the line around the coils of said generator.

19. In a superposed-current telegraph, the combination of an inductance in a main line and a pulsatory-current transmitter adapted to close and open a shunt around the same, a continuous-current receiver, and a condenser in said shunt for obviating disturbances in the continuous-current receiver through variations of line-resistance produced by the action of said transmitter.

707,830. **TELEGRAPHY.** ALBERT C. CREHORE, Tarrytown, N. Y. Filed Oct. 21, 1901. Serial No. 79,347. (No model.)



Claim.—1. In a superposed-current telegraph, the combination substantially as described of a pulsatory-current generator adapted to generate an approximate sine-wave electromotive force and condenser shunts or branches around apparatus for the continuous-current side of the system each said shunt having its capacity balanced by inductance, as and for the purpose set forth.

2. In a superposed-current telegraph, the combination with an approximate sine-wave pulsatory-current generator for the pulsatory-current side of the system, a transmitter for the continuous current side of the system a condenser-shunt around the latter and a balancing-inductance in said shunt, said inductance, condenser capacity and frequency of pulsations being related to one another as described, as and for the purpose set forth.

3. In a superposed-current telegraph, the combination with a pulsatory-current generator adapted to generate electromotive force of the sine-wave type, a continuous-current receiver and transmitter, and a shunt to the same containing a condenser and inductance related to one another and to the frequency of the pulsations in the manner described to reduce the impedance of said shunt, as and for the purpose set forth.

4. In a superposed-current system of telegraphy, a condenser-shunt containing a receiver for the pulsatory-current side of the system in combination with a pulsatory-current generator of the sine-wave type, the frequency of the pulsations, the reactance of the receiver and the capacity of the condenser being related to one another as described to increase the strength of current permissible at the transmitting end of the line.

5. A superposed-current system of telegraphy having a sine-wave generator for the pulsatory-current side and shunts around the continuous-current apparatus at way-stations comprising a condenser and balancing-inductance related to one another as and for the purpose described.

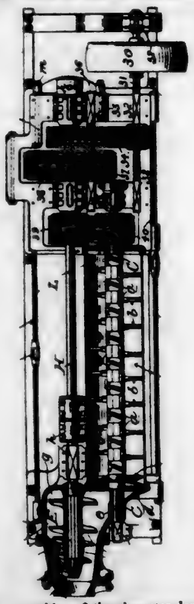
6. In a superposed-current telegraph, the combination with a pulsatory-current generator adapted to generate an electromotive force of sine-wave type, a continuous-current transmitter and receiver and a shunt around said transmitter and receiver containing a condenser, and an inductance whose reactance is adapted to balance the reactance of said condenser.

7. In a superposed-current telegraph, the combination substantially as described with a continuous-current transmitter and its condenser-shunt, of a balancing-inductance in the condenser-shunt adapted to furnish a reactance that will balance the opposing reactance of the condenser, as and for the purpose described.

8. In a superposed-current telegraph, the combination substantially as described with the continuous-current apparatus, of a condenser-shunt having a balancing-reactance composed of a coil wound on an iron core magnetically closed except for the presence of a narrow gap, as and for the purpose set forth.

9. In a superposed-current system of telegraphy, the combination with a condenser shunt through which the pulsatory currents flow for operating on the pulsatory-current receiver, of a suitable inductance having a reactance adapted to balance the reactance of said condenser.

707,831. **COMBINED TILE-MACHINE AND PUG-MILL.** WILLIAM R. CUNNINGHAM, Bucyrus, Ohio, assignor to the American Clay Working Machinery Company, Bucyrus, Ohio, a Corporation of Ohio. Filed Apr. 16, 1902. Serial No. 103,236. (No model.)



Claim.—1. In a machine of the character described the combination of two separate and independent cylinders placed substantially in the same horizontal plane and means connecting the discharge end of one cylinder with the inlet end of the other cylinder, one of said cylinders having clay-tempering devices and the other cylinder having a clay-expressing mechanism and said devices and mechanism extending parallel and in the same direction.

2. In a machine of the character described the combination of two separate and independent cylinders placed in different vertical planes and substantially in a common horizontal plane, and a forwardly-inclined lateral passage connecting the outlet end of one cylinder with the inlet end of the other cylinder; a shaft extending through one of the cylinders and provided with mixing and tempering devices; a shaft passing through

the other cylinder, and provided with an expressing mechanism, said mixing and tempering devices and expressing mechanism extending parallel in the same direction, and a prime mover and power-transmitting mechanism between the same and the said shafts, for rotating the latter.

2. In a machine of the character described, the combination of two separate and independent cylinders of unequal length extending in the same direction and placed horizontally substantially side by side, and with the outlet of one cylinder connecting horizontally with the inlet of the other cylinder; a shaft extending through one of said cylinders and provided with mixing or tempering blades, and a propeller or auger arranged proximate to the discharge end of the cylinder; a shaft passing through the other cylinder; and a propeller or auger on said second shaft and receiving the discharge from the first-named propeller and expressing it through the outlet of the second cylinder; said shafts extending in the same direction and means for operating said shafts.

4. In a machine of the character described the combination of a horizontally-disposed cylinder; a shaft passing therethrough, and provided with clay mixing and tempering blades, and a propeller on said shaft proximate to the discharge end of the cylinder; a second cylinder offsetting in a horizontal plane the first-named cylinder, and extending forward of and in the same direction as the first-named cylinder, and having a horizontally-curved wall forming a lateral, forwardly-inclined, throat between the discharge end of one cylinder and the inlet end of the other cylinder; a shaft passing through the second cylinder and provided with an expressing propeller or auger, adapted to receive the clay forced through said throat by the first-named propeller and express it through the discharge end of the second cylinder without materially changing the direction of travel of the clay; and power-transmitting mechanism for operating said shafts.

707,882. BLUE DYE AND PROCESS OF MAKING SAME. CHAS. DE LA HARPE, Basle, Switzerland, assignor to The Firm of Dye Works formerly L. Durand, Huguenin & Co., Basle, Switzerland. Filed Feb. 27, 1902. Serial No. 96,998. (Specimens.)

Claim.—1. An improvement in the manufacture of blue dyestuffs, consisting in treating a sulfonic gallocyanin derived from a nitrosoalkylbenzylanilinsulfonic acid, by sulfurous acid.

2. An improvement in the manufacture of blue dyestuffs, consisting in treating a sulfonic gallocyanin derived from the nitrosoethylbenzylanilinsulfonic acid by sulfurous acid.

3. As a new article of manufacture, the herein-described blue dyestuff obtained from a gallocyanin derived from a nitrosoalkylbenzylanilinsulfonic acid, the said dyestuff being soluble in sodium acetate with a pale-blue coloration and giving with concentrated sulfuric acid a reddish solution turning to blue by addition of an oxidizing agent, this dyestuff dyeing chromium-mordanted fibers in blue shades.

707,883. BLUE DYE AND PROCESS OF MAKING SAME. CHAS. DE LA HARPE, Basle, Switzerland, assignor to Firm of Dye Works formerly L. Durand, Huguenin & Co., Basle, Switzerland. Filed Feb. 27, 1902. Serial No. 96,994. (Specimens.)

Claim.—1. The herein-described improvement in the manufacture of blue dyestuffs, consisting in condensing a phenol with a sulfonic gallocyanin.

2. The herein-described improvement in the manufacture of blue dyestuffs, consisting in condensing a phenol with a sulfonic gallocyanin derived from a nitrosoalkylbenzylanilin-sulfonic acid.

3. The herein-described improvement in the manufacture of blue dyestuffs, consisting in condensing resorcin with a sulfonic gallocyanin derived from a nitrosoalkylbenzylanilin-sulfonic acid.

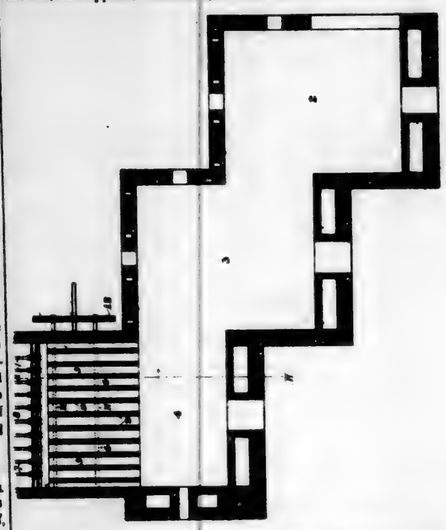
4. The herein-described improvement in the manufacture of blue dyestuffs, consisting in condensing resorcin with a sulfonic gallocyanin derived from the nitrosoethylbenzylanilin-sulfonic acid.

5. As a new article of manufacture, the herein-described blue dyestuff obtained by the condensation of the resorcin with a gallocyanin resulting from a nitrosoalkylbenzylanilin-sulfonic acid, the said dyestuff constituting in dry state a bluish powder very sparingly soluble in cold water, soluble in sodium acetate and alkalies and dying chromium mordanted fibers in pure blue shades.

707,884. PLATE-GLASS-ANNEALING APPARATUS. HENRY L. DERST, Pittsburg, Pa. Filed May 6, 1901. Serial No. 58,570. (No model.)

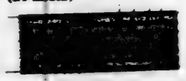
Claim.—1. The combination with a lear having longitudinally-movable bars, of transfer mechanism arranged to lift a glass plate and carry it longitudinally to a position over the bar-supports; substantially as described.

2. In plate-glass-annealing apparatus, a lear having movable bars with supports therefor at the front end of the lear, a supporting floor or platform in front of the lear, and transfer mechanism arranged to lift the glass plate from the floor or platform and carry it rearwardly to a point over the bar-supports; substantially as described.



3. The combination with a lear, of a tile floor or platform in front of it, and having transfer-bars therein, and rock-arms arranged to lift the bars and plate and carry them rearwardly over the front supports for the lear-bars; substantially as described.

707,885. MEANS FOR GENERATING COUNTER ELECTROMOTIVE FORCE. HERBERT H. DOW, Midland, Mich. Filed Apr. 21, 1900. Serial No. 13,707. (No model.)



Claim.—1. A voltaic element comprising electrodes and a suitable electrolyte, the opposing faces of said electrodes being of opposite sign and of a granular construction, said electrodes and their faces being of similar material.

2. A voltaic element comprising electrodes and a suitable electrolyte, such electrodes having their respective opposing faces of opposite sign and provided with a covering of granular material, said electrodes and covering being of similar material.

3. A voltaic element comprising electrodes and a suitable electrolyte, such electrodes consisting of sheets of carbon having their opposing faces provided with a covering of granular carbon, said faces being of opposite sign.

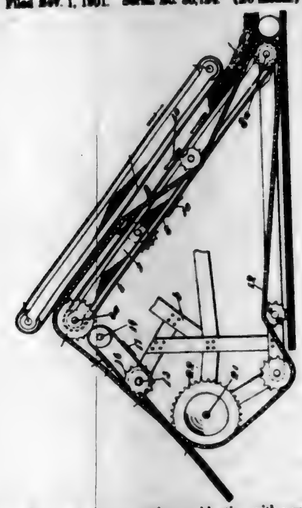
4. A voltaic element comprising electrodes, a suitable electrolyte and bibulous material, opposing faces of such electrodes being of opposite sign and having a granular construction and in contact with opposite faces of such bibulous material, said electrodes and their faces being of similar material.

5. A voltaic element comprising electrodes, a suitable electrolyte and bibulous material, such electrodes consisting of sheets of carbon having their opposing faces of opposite sign and formed of a covering of granular material of a character similar to that of the electrodes, such material being in contact with opposite faces of such bibulous material.

6. A series of voltaic elements each comprising electrodes and an electrolyte, opposing faces of adjacent electrodes being of opposite signs and formed with a covering of granular material of a character similar to that of the electrodes, opposite faces of such electrodes constituting the anode and cathode respectively of two adjacent elements.

7. A series of voltaic elements each comprising electrodes, an electrolyte and bibulous material, opposing faces of adjacent electrodes being of opposite signs and formed with a covering of granular material of a character similar to that of the electrodes upon opposite sides of said bibulous material, opposite surfaces of such electrodes constituting the anode and cathode respectively of two adjacent elements.

707,886. GRAIN-HARVESTER. HOMER P. FISLEY, Ann Arbor, Mich. Filed Nov. 1, 1901. Serial No. 80,794. (No model.)



Claim.—In a grain-harvester the combination with a grain-elevator and a stationary deck arranged stubbleward of the top portion thereof, of a movable grain-deck held between the elevator and the stationary deck and comprising two rollers mounted respectively in proximity to said elevator and the stationary grain-deck, and an endless belt or conveyer mounted on said rollers and of a width equal to the width of the grain-deck and means for moving the endless belt, at a higher speed than the elevator, substantially as shown and described.

707,887. SHEET-PILING. LUTHER P. FRIESNER, Chicago, Ill. Filed Dec. 2, 1901. Serial No. 84,602. (No model.)

Claim.—1. A metal sheet-piling, comprising a series of beams having interlocking flanged edges and joined together in the relative alternating position shown, and presenting a single wall at all points, substantially as set forth.

2. A metal sheet-piling, comprising a series of channel-beams having engaging interlocking flanged edges, the joining faces of said flanges being beveled and which draw together with a wedging action as the beams are assembled in their alternating position in forming a structure presenting a single wall at all points, substantially as set forth.

3. A metal sheet-piling, composed of channel-beams joined edgewise and having the back and face sides thereof positioned alternately with reference to each other, and presenting a wall structure of a single thickness at all points, substantially as set forth.

4. A metal sheet-piling, composed of beam-sections assembled edgewise and presenting a single wall at all points, and means for locking said beams together, substantially as set forth.

5. In metal sheet-piling, the combination with a series of channel-beams positioned alternately and interlocked along their flanged edges in continuous order of succession, of an angle Z-bar joining and bracing the beam-sections, substantially as set forth.

6. In metal sheet-piling, the combination with a series of channel-beams joined together in a continuous unbroken sheet, by having the respective flanged edges interlock, of the double angle-bars, and the angle-plates positioned opposite to said bars and providing a space for the insertion of a packing substance, substantially as set forth.

707,888. UMBRELLA-RUNNER. WILLIAM H. GAMBLE, Philadelphia, Pa., assignor to Samuel W. Evans, Jr., Philadelphia, Pa. Filed Nov. 16, 1900. Serial No. 36,573. (No model.)

Claim.—1. In a spring-case for an umbrella, a tube, and a ring having a collar, the latter being provided with an annular groove on the exterior thereof, the contiguous metal of said tube being deflected into said groove and secured to the wall thereof.

2. In a spring-case for an umbrella, an exterior tube, a ring having a collar, said collar being provided with an annular groove on the exterior thereof, the contiguous metal of the exterior tube being deflected into said groove and engaging with the surface of said collar on opposite sides of said groove.

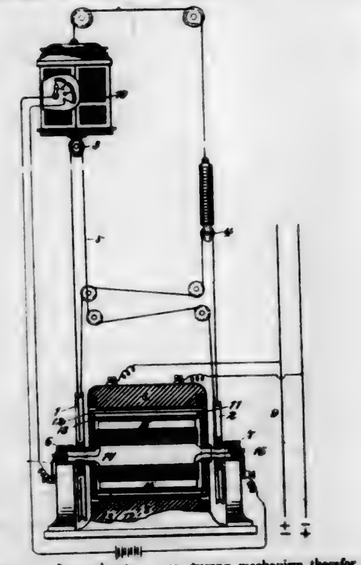
3. In a spring-case for an umbrella, a ring having a collar, a groove on the exterior of said collar, and an exterior tube having its upper extremity knurled or otherwise deflected into said groove, the lower portion of said exterior tube being of reduced diameter.

4. A runner for a self-opening umbrella, consisting of a body portion having a ring attached thereto, said ring having an outer downwardly-deflected peripheral lip or flange, and an inner annular strengthening device between said lip and the inner wall of said ring whereby the upper portion of said ring is prevented from being crushed inwardly in the act of wiring the stretchers in position.

5. As an improved article of manufacture, a runner having an annular groove at its upper portion, said groove being closed at its top and open at its bottom, and annularly-disposed strengthening means on the inner wall of said groove between the inner and outer walls of the ring, whereby the upper portion of the device is prevented from being crushed inwardly during the wiring of the stretchers in position.

6. A spring-case for an umbrella consisting of an interior tube, a notched ring having a collar, said ring and collar being carried by said tube, said collar being provided with an annular groove on the exterior thereof, and an exterior tube, the metal of which latter is deflected into said groove and engaged with the portion of said collar on the opposite sides of said groove.

707,889. ELEVATOR. EDWIN R. GILL, New York, N.Y., assignor to Invention Developing Company, a Corporation of New Jersey. Filed Dec. 16, 1899. Serial No. 740,594. (No model.)



Claim.—1. In an elevator, a car, driving mechanism therefor, rotary magnetizable poles adapted to turn therewith, a magnetizing-circuit for said poles, means on the car for varying the current in said circuit, a closed rotatable circuit close to said magnetizable poles and means for imparting rotary movement to said closed circuit.

2. In an elevator, a car balanced so as to tend by gravity to move in one direction, driving mechanism therefor, constantly-moving motive means adapted to operate through said driving mechanism to counteract said gravitative tendency and means for regulating the power of said motive means from zero to a maximum sufficient to move said car against

said gravitative tendency without substantially changing the speed of said mechanism.

3. In an elevator, a car, driving mechanism therefor, rotary magnetizable poles adapted to turn therewith, a magnetizing-circuit for said poles, a closed rotatable circuit close to said magnetizable poles, an electric motor for driving said closed circuit continuously, a generator operated by said motor and supplying current to said magnetizing-circuit and means for controlling said magnetizing-current.

4. In an elevator, a car, driving mechanism therefor, rotary magnetizable poles adapted to turn therewith, a magnetizing-circuit for said poles, a closed rotatable circuit close to said magnetizable poles, an alternating-current motor for driving said closed circuit continuously, a generator operated by said motor and supplying current to motor field-magnets and to said magnetizing-circuit, and means for controlling said magnetizing-current.

5. In an elevator, a car, driving mechanism therefor, constantly-rotating motive means, an inducing and an induced electromagnetic transmission member, one of said members being operatively connected to said driving mechanism and the other to said motive means, and means for operatively varying the electromagnetic reaction between said transmission members.

707,840. METHOD OF BALLASTING RAILWAY-TRACKS. WILLIAM GOLDER, Wilkinsburg, Pa. Filed Jan. 10, 1902. Serial No. 89,147. (No model.)

Claim.—1. The method of surfacing railroad-tracks, consisting in injecting cement under the ties to form supporting-beds therefor, said cement being moistened sufficiently to cause the same to set but not sufficiently to render the same fluid or mobile.

2. The method of surfacing railroad-tracks, consisting in injecting cement under the ties to form supporting-beds therefor, and simultaneously therewith supplying sufficient moisture thereto to cause the same to set but not to become fluid or mobile.

3. The method of surfacing railroad-tracks, consisting in injecting cement under the ties to form supporting-beds therefor, and simultaneously therewith moistening the same with a spray of atomized water.

4. The method of surfacing railroad-tracks, consisting in raising the tie and then injecting cement under the same to form supporting-beds therefor, said cement being slightly moistened to cause the same to set but not sufficiently to cause the same to become fluid or mobile.

5. The method of surfacing railroad-tracks, consisting in tamping the ballast under the ends of the ties, and injecting cement under the ties underneath the rails to form supporting-beds therefor, said cement being moistened sufficiently to cause it to set but not sufficiently to cause it to flow or become plastic.

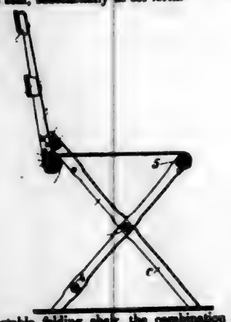
6. The method of surfacing railroad-tracks, consisting in placing dam-plates at the sides of the ties underneath the rails and injecting cement under the ties to form supporting-beds therefor, said cement being moistened sufficiently to cause it to set but not sufficiently to cause it to flow or become plastic.

7. The method of surfacing railroad-tracks, consisting in injecting under the ties by means of fluid-pressure cement to form supporting-beds therefor, and simultaneously therewith admitting a small stream of water to the fluid-pressure pipe whereby the water is atomized and mingled with the cement.

8. The method of surfacing railroad-tracks, which consists in injecting under the ties by means of fluid-pressure cement in a practically dry state, and simultaneously therewith drawing by means of said fluid-pressure a small stream of water into the fluid-pressure pipe whereby the water is atomized and mixed with the cement.

707,841. PORTABLE FOLDING CHAIR. BENJAMIN J. HARRISON, Whitestone, N. Y., assignor to Anna May Harrison, Whitestone, N. Y. Filed Dec. 23, 1901. Serial No. 87,222. (No model.)

Claim.—1. The combination with the pairs of pivoted folding X-legs, of a back-frame, a flexible seat secured at one end to the inner frame of the pairs of X-legs, a cross-bar connected to the lower ends of the back-frame and to which the other end of the flexible seat is secured, the flexible seat being longitudinally of full width and agreeing in width with its supports, and devices for pivotally connecting the said back-frame to and between the inner surfaces of the outer pair of pivoted X-legs at a point forward of the back-frame and above the point of attachment to the cross-bar of the flexible seat, substantially as set forth.



2. In a portable folding chair, the combination with the pairs of folding X-legs, the back-frame and the flexible seat, of plates secured to the outer faces of the side bars of the back-frame and projecting forward of the edge face of the side bars, and pivot-bolts connecting said plates to the upper end of the longer members of the X-legs, whereby the flexible seat in width agrees with the width of the back-frame and leg-frame and the back-frame is adapted to fold over upon the flexible seat and leg-frame, substantially as set forth.

3. In a portable folding chair, the combination with the pairs of folding X-legs and the back-frame pivoted thereto, of a cross-bar longer than the width of the back-frame, a part adapted to be connected thereto and means for securing the cross-bar to the lower ends of the back-frame side bars below and beyond the points of pivotal connection of the said back-frame to the folding X-legs, and a flexible seat secured at one end to the inner frame of the pairs of X-legs and at the other end and in its full width to the said cross-bar of the back-frame between the same and the parts adapted to be connected thereto, substantially as set forth.

4. In a portable folding chair, the combination with the pairs of pivoted folding X-legs, the back-frame pivoted thereto and the flexible seat, of a cross-bar having a longitudinally-flattened surface, and notches providing faces in the axial plane of the bar, a strip of wood and means for securing the same to the cross-bar with one end of the flexible seat intervening, said end of the flexible seat also intervening between the notched ends and the lower ends of the back-frame side bars, substantially as set forth.

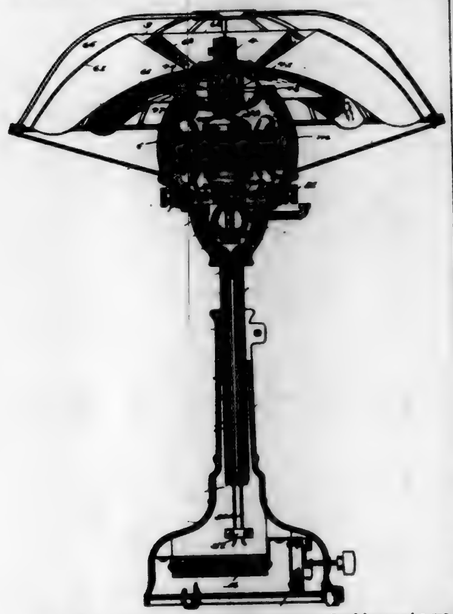
5. In a portable folding chair, the combination with the pairs of pivoted folding X-legs and the flexible seat connected at one end thereto, of the back-frame side bars having notches at their lower ends at inclinations which are substantially acute angles to the edge faces, pivotal connections for the side bars to the longer members of the pairs of X-legs adjacent to said notched ends but appreciably distant therefrom, a cross-bar of circular form in cross-section with a longitudinally-flattened portion and ends notched to provide faces in axial planes, a strip of wood and screws for securing part of one end of the flexible seat to the said cross-bar between the side bars of the back-frame, the said flexible seat being notched at the corners of the angular notches at the ends of the side bars and the sides of the flexible seat at the same end being between the notched ends of the side bar and the notched ends of the cross-bar, whereby this end of the flexible seat is securely held over its entire length both at the end where the same is notched and adjacent thereto over an unbroken portion, substantially as set forth.

707,842. ELECTRIC FAN. GARDNER C. HAWKINS, Boston, and HERBERT L. PLIFF, Cambridge, Mass., assignors to Boston Electric Heating and Power Company, Portland, Me., and Boston, Mass., a Corporation of Maine. Filed Mar. 20, 1901. Serial No. 52,402. (No model.)

Claim.—1. In an electric fan, a telescopic standard carrying at its upper end a motor having a vertically-arranged armature-shaft, means to clamp the sections of the standard together in any adjusted position, a fan secured to the upper end of said shaft, extensible conductors within the standard and connected to the motor, and a controller for the motor carried by said standard, the construction being such that the motor may be operated at any adjusted position of the standard.

2. In an electric fan, a standard, comprising a base and a motor-frame having a hollow stem, said stem being vertically adjustable in the base, a motor in said frame having a vertically-arranged armature-shaft, a fan attached to said shaft and telescopic electrical connections inclosed in the hollow stem and connected to the motor.

3. In an electric fan, a standard comprising a fixed base and a vertically-adjustable motor-frame, said frame having a hollow stem which telescopes into the base of the standard, a motor in said frame, and a fan operated by said motor, means to clamp said base and standard together to hold the fan at any desired vertical elevation, fixed terminals in said base and frame respectively, extensible electrical connections inclosed by said hollow stem and connecting the terminals in the base with those of the frame, and a controller in said base for regulating the speed of the fan.



4. In an electric fan, a standard comprising a fixed base and a motor-frame, said frame having a hollow stem which is vertically adjustable in the base, a motor in said frame, a fan operated by said motor, a switch in said base, and extensible electrical conductors inclosed by said hollow stem and connecting the switch and motor.

5. In an electric fan, a standard comprising a fixed base and a motor-frame having a hollow stem, said stem being vertically adjustable in said base, a motor in said frame, a fan operated by said motor, a resistance-coil and a switch in said base, and extensible conductors between the switch and motor whereby the motor may be operated at any adjusted position of the motor-frame.

6. In an electric fan, a standard comprising a base and a motor-frame having a hollow stem, said stem being vertically adjustable in said base, a motor in said frame having a vertically-arranged armature-shaft, a fan attached to said shaft, a switch in said base, and telescopic electrical connections inclosed in the hollow stem and connecting the switch and motor.

7. In an electric fan, a standard comprising a base and a motor-frame having a hollow stem, said stem being vertically adjustable in said base, a motor in said frame having a vertically-arranged armature-shaft, a fan attached to the upper end of said shaft, a switch in said base, and extensible electrical connections between said switch and motor and inclosed by said hollow stem, said connections comprising conductors fixed to the frame and base and having a sliding connection with each other.

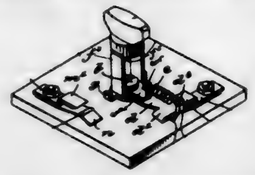
8. In an electric fan, a standard comprising a base and a motor-frame having a hollow stem, said stem being vertically adjustable in said base, a motor in said frame having a vertically-arranged armature-shaft, a fan attached to the upper end of said shaft, a switch in said base, and extensible electrical connections between said switch and motor and inclosed by said hollow stem, said connections comprising tubes inclosed in said hollow stem, and wires attached to the base and telescoping in the said tubes.

9. In an electric fan, a motor having a vertically-arranged armature-shaft, a fan attached to said shaft at the upper end thereof, a step-bearing between the motor and fan for supporting the armature-shaft, said bearing comprising a stationary cup member having an aperture larger than the shaft and through which the shaft projects, and a collar fast on the shaft and having a depending flange which rests in the cup-bearing but is spaced from the inner wall thereof, and a centering device for the lower end of the shaft, said centering device comprising a vertical oil-cup with a closed bottom and into which the lower end of the shaft projects, said oil-cup engaging the shaft on the circumference thereof only.

10. In an electric fan, a motor having a vertically-arranged armature-shaft, a fan attached to the upper end of said shaft, a step-bearing between the fan and the motor for supporting said shaft, an oil-cup adapted to receive the lower end of the shaft and having means to center said shaft, and a collar or flange fixed to said shaft, said collar being smaller than and situated within the mouth of the oil-cup whereby oil is prevented from working up the armature-shaft past the collar.

11. In an electric fan, a standard comprising a base portion, and a motor-frame having a hollow stem, said stem being vertically adjustable in the base, a motor in said frame having a vertically-arranged armature-shaft, a fan attached to said shaft, said fan operating to deliver a current of air at an angle to its axis of rotation, and extensible electrical connections inclosed in said hollow stem, and a controller in the base of the motor, the said construction being such that by varying the height of the motor frame the circular area affected by the fan may be increased or diminished.

707,843. ELECTRIC SWITCH OR CUT-OUT. JOHN A. HENRY, Philadelphia, Pa., assignor to the Peter Henry Developing Company, Charleston, W. Va., and Philadelphia, Pa., a Corporation of West Virginia. Filed Dec. 11, 1901. Serial No. 85,494. (No model.)



Claim.—1. In an electric switch or cut-out, a traveling contact-bar, a series of stationary contacts, means for locking the contact bar to each contact, an operating-plate, a spring connecting the operating-plate to the contact-bar, means controlled by the movement of the operating-plate for distending the spring, and means carried by said operating-plate and adapted to engage and force the contact-bar from the contact to permit the distended spring to further move the contact-bar into locking engagement with the next contact in series.

2. In an electric switch or cut-out, the combination of a traveling contact-bar pivoted at one end in an insulating-base, the free end of said bar having locking means, a plate also pivoted upon the pivotal connection of the contact-bar, a spring connecting the free ends of the contact-bar and said plate, lugs formed on the contact-bar adjacent to its pivotal connection and adapted to be engaged by the plate in the turning of said plate, and a series of stationary contacts, each adapted to receive the free end of the contact-bar and to lock the same in the contact, all arranged so that when the plate is turned, the spring is distended until the plate strikes a lug upon the traveling contact-bar and thereafter the bar is released from a contact and is snapped into locking engagement with the next contact by said spring.

707,844. ELECTRIC-RAILWAY SYSTEM. JOHN C. HENRY, Denver, Colo.; Dante A. Henry, executrix of said John C. Henry, deceased, assignor to Stanley Electric Manufacturing Company, a Corporation of New Jersey. Filed Apr. 9, 1901. Serial No. 55,102. (No model.)

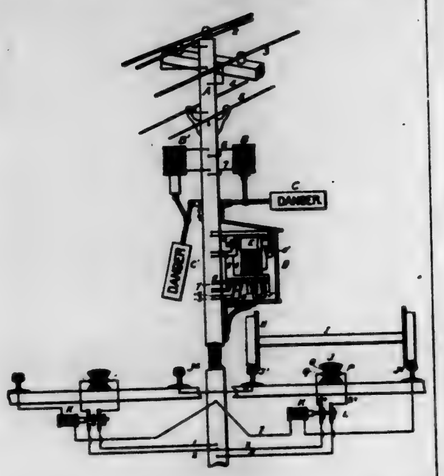
Claim.—1. In a distribution system for electric railways, where the working conductors are located below the cars, an I-beam arranged along the roadway having the working conductors protected by its flanges, said conductors being supported in position by a plastic insulating material and insulated thereby.

2. In a third-rail system, working conductors supported and protected by an I-beam, and insulated therefrom, said beam having its flanges arranged in a horizontal direction, the latter being bent in a curved form substantially as shown so as to stiffen the beam and to leave a downtaled aperture to retain the insulating material and conductors.

3. In a third-rail system conductors arranged and insulated within the side openings of an I-beam, said beam having its flanges bent together, substantially as shown.

4. An electric-railway system comprising trunk-sections, sectional working conductors, a direct-current-supply circuit and switching devices connecting same with the working conductors, and a plurality of local circuits each connected to a trunk-section and including a converting de-

vice whereby it is energized inductively from the supply-circuit, and means in said local circuit for controlling said switching device.



5. An electric railway comprising trunk-sections, sectional working conductors, and electromagnetically-controlled switching devices connecting same with the working conductors, electromagnetic sumaphore devices, and a plurality of local circuits connected to the trunk-sections and including the controlling-magnets of said switch and sumaphore devices, and subdivided and distributed induction devices connected to the supply-circuit and to the local circuits to energize the latter.

6. An electric-railway system comprising trunk-sections, sectional working conductors, direct-current-supply conductors and electromagnetically-controlled switches controlling the connection from the supply-conductors to the working conductors, and subdivided and distributed converters energized by the supply-circuit and connected to the trunk-sections and to the electromagnetic switches to control the latter.

7. An electric-railway system comprising trunk-sections, a direct-current-supply circuit, sectional conductors and switches controlling their connection with the supply-circuit, local circuits connected to the trunk-sections and including electromagnets controlling such switches, rotary converters connected to the direct-current-supply circuit, and distributing-circuits receiving alternating current from the rotary converters and including stationary converters connected to energize, by induction, the local trunk-section circuits.

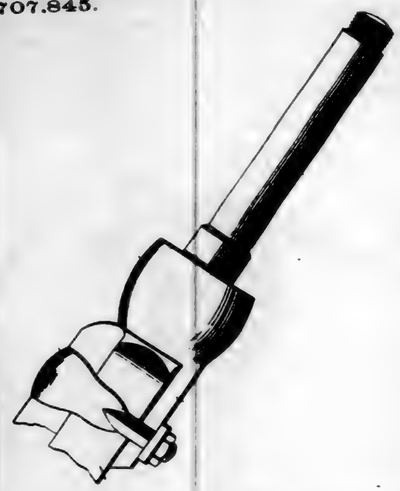
8. An electric-railway system comprising trunk-sections, a direct-current-supply circuit, sectional conductors and switches controlling their connection with the supply-circuit, local circuits connected to the trunk-sections and including electromagnets controlling such switches, electromagnetic sumaphore devices included in the local circuits, rotary converters connected to the direct-current-supply circuit, and distributing-circuits receiving alternating current from the rotary converters and including stationary converters connected to energize, by induction, the local trunk-section circuits.

9. The combination with the sectional working conductors and the direct-current-supply circuit of electromagnetically-controlled switches controlling the connection from said supply-circuit to the working conductors, trunk-sections, subdivided and distributed induction devices connected to said trunk-sections and switching devices, to operate the latter, and means for supplying alternating current to energize said induction devices.

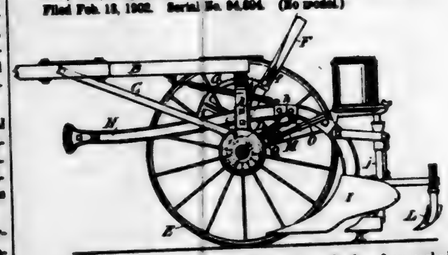
707,845. VEHICLE-AXLE. HARRY EDWARD and ARTHUR E. MATTHEWS, Dundee, Tay. Filed Mar. 6, 1902. Serial No. 96,955. (No model.)

Claim.—The combination with a vehicle-axle provided with an enlarged screw-threaded end; of a spindle provided with an enlarged internally-threaded cap to be screwed upon said end, and a spring-arm projecting inwardly from said spindle-end, in the act of screwing the spindle to the axle, adapted to freely pass the corners of the axle, and a clip for changing the arm into engagement with the axle, substantially as described.

707,845.



707,846. REEDING-MACHINE. EDWARD M. HEYLMAN, Janesville, Wis., assignor to Janesville Machine Company, Janesville, Wis. Filed Feb. 13, 1902. Serial No. 94,894. (No model.)



Claim.—1. The combination with carrying-wheels, of an arched axle, a gear-casing journaled on said axle and provided with a sleeve, and a driving-gear journaled on said sleeve and operated by one of said carrying-wheels, substantially as shown and described.

2. The combination with carrying-wheels, of a crank-axle, a driving-gear, a gear-casing mounted on said axle, a pinion-housing pivoted to said casing, and a rotating shaft provided with a pinion and journaled in said housing, substantially as shown and described.

3. The combination with carrying-wheels, of an arched axle, a gear-casing mounted on said axle, a driving-gear, a pinion-housing pivoted to said casing, a rotating shaft provided with a pinion journaled in said housing, a clutch adapted to slide on said shaft, and means for sliding said clutch on said shaft, substantially as shown and described.

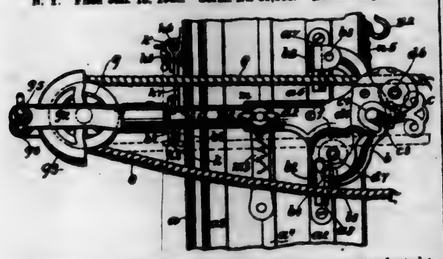
4. The combination with carrying-wheels, of an arched axle, a gear-casing mounted on said axle, a driving-gear, a pinion-housing pivoted to said casing, a rotating shaft journaled in said housing and provided with a pinion, a sliding clutch mounted on said rotating shaft and adapted to engage said pinion, a pivoted lever adapted to slide said clutch longitudinally of said shaft, and an inclined flange arranged in close proximity to one end of said lever, substantially as shown and described.

5. The combination with carrying-wheels, of a crank-axle, a gear-casing journaled on said axle, a driving gear journaled in said casing, a pinion-housing pivoted to said casing, a rotating shaft journaled in said casing, a pinion adapted to rotate on said shaft, and a clutch adapted to slide on said shaft and to have a locking engagement with said pinion, substantially as shown and described.

6. The combination with a pivoted housing, of a rotating shaft having one end journaled in said housing, a pinion adapted to rotate on said shaft and provided with a hub having a shoulder adapted to bear against said housing, and a collar rigidly secured to said shaft and arranged between said pinion and housing, substantially as shown and described.

7. The combination with carrying-wheels, of a crank-axle, a plow-beam mounted on said axle, a gear-casing journaled on said axle, a driving-gear journaled on said casing, a pinion-housing pivoted to said gear-casing, a rotating shaft journaled in said housing, a pinion loosely mounted on said shaft and journaled in said housing, a clutch having a sliding engagement with said pinion, an inclined flange, and a lever adapted to engage said clutch and flange and remove said clutch from engagement with said pinion, substantially as shown and described.

707,847. CLOTHES-LINE HOLDER. ALFRED H. JOHN, Brooklyn, N. Y. Filed Jan. 15, 1902. Serial No. 89,988. (No model.)



Claim.—1. A clothes-line holder comprising a support adapted to be connected with a window-frame, and an arm connected with one end of said support by a ball-and-socket joint, so as to be swung diagonally of the frame, said arm being provided at its opposite end with a pulley and at the end thereof connected with said support with two pulleys, one of which is above and the other below said ball-and-socket joint, substantially as shown and described.

2. A clothes-line holder comprising a support adapted to be connected with a window-frame, and an arm connected with said support at one end by a ball-and-socket joint so as to be swung diagonally of the frame and provided at its opposite end with a detachable pulley, said arm being also provided at the end thereof which is connected to said support with two pulleys, one end of which is arranged above and the other below the ball-and-socket joint, and said detachable pulley being supported at a lateral angle to the said arm, substantially as shown and described.

3. A clothes-line holder comprising a support adapted to be connected with a window-frame so as to swing laterally, means for adjusting said support to any desired lateral position, an arm connected at one end with said support by a ball-and-socket joint so as to be swung at an angle to the side of the frame and provided at said end with two pulleys, one of which is arranged above and the other below said ball-and-socket joint, said arm being also provided at its free end with a pulley, substantially as shown and described.

4. A clothes-line holder comprising a support adapted to be connected with a window-frame and to swing laterally thereon, an arm connected at one end with said support by a ball-and-socket joint so as to swing at an angle to said frame and provided above and below said joint with a pulley, said arm being also provided in its opposite end with a pulley, and a clamp adjustable transversely of the window-frame and adapted to hold said arm, substantially as shown and described.

5. A clothes-line holder comprising a support adapted to be connected with a window-frame and to swing toward and from said frame, means for adjusting the position of said support, an arm connected at one end with said support by a ball-and-socket joint and provided above and below said joint with pulleys, a detachable pulley mounted in the opposite end of said arm, and a clamp adjustable transversely of the window-frame and adapted to receive said arm, substantially as shown and described.

6. A clothes-line holder comprising a support adapted to be connected with a window-frame and to swing toward and from said frame, means for adjusting the position of said support, an arm connected at one end with said support by a ball-and-socket joint and provided above and below said joint with pulleys, a detachable pulley mounted in the opposite end of said arm, and a clamp adjustable transversely of the window-frame and adapted to receive said arm, said detachable pulley being supported at an inclination to a horizontal plane, substantially as shown and described.

7. A clothes-line holder comprising a spanner-yoke adapted to be connected with a window-frame so as to swing in a horizontal plane, devices for adjusting the position of said yoke with reference to said frame, part of which devices are detachably connected with said frame, an arm connected with one end of said spanner-yoke by means of a ball-and-socket joint and provided at said end and above and below said joint with pulleys, and a pulley mounted in the opposite end of said arm, substantially as shown and described.

8. A clothes-line holder comprising a spanner-yoke adapted to be connected with a window-frame and to swing in a horizontal plane, devices for holding said yoke in any desired position and part of which are detachably connected with said frame, an arm connected at one end with said support by means of a ball-and-socket joint and provided above and below said joint with pulleys, a detachable pulley mounted in the opposite end of said arm, and a clamp adapted to be connected with the window-frame and adjustable transversely thereof and adapted to receive said arm, substantially as shown and described.

9. In a device of the class described, a support connected with the window-frame and adapted to swing in a horizontal plane, an arm connected with said support by a ball-and-socket joint, and a clamp adjustable transversely of the window-frame and comprising a jaw adapted to swing in a horizontal plane, and a supplemental jaw pivotally connected therewith and adapted to swing in a vertical plane, said clamp being adapted to receive and hold said arm, substantially as shown and described.

10. In a clothes-line holder, a yoke adapted to be connected with a window-frame so as to swing in a horizontal plane, means for regulating the position of said yoke, an arm connected at one end with said yoke by means of a universal joint, said arm being provided at said end and above and below said joint with a pulley, a pulley connected with the opposite end of said arm, and a brace pivotally connected with said arm and adapted to be connected with said yoke, substantially as shown and described.

11. In a clothes-line holder comprising a yoke adapted to be connected with a window-frame so as to swing in a horizontal plane, devices for adjusting the position of said yoke, a part of which is adapted to be detachably connected with said frame, an arm connected with said yoke by a ball-and-socket joint and provided above and below said joint with a pulley and a supplemental pulley mounted in the opposite end of said yoke and detachable therefrom, substantially as shown and described.

12. In a clothes-line holder, a yoke adapted to be connected with a window-frame and to swing in a horizontal plane, devices for securing said yoke in any desired position, part of which consists of a plate hinged to the window-frame by means of a detachable pintle, an arm connected with said yoke by a ball-and-socket joint and provided above and below said joint with a pulley and a detachable pulley mounted in the opposite end of said arm, substantially as shown and described.

13. In a clothes-line holder, an arm provided with a yoke, the sides of which are segmental in cross-section and provided with inwardly-directed shoulders or projections and a pulley support provided with side members which are also segmental in cross-section and through which the shaft of the pulley is passed, said pulley-support being also provided with a swiveled eye and said yoke with a pin or bolt which is passed through the ends of the sides thereof and through said eye, substantially as shown and described.

14. In a device of the class described, an arm d provided with a sleeve d^2 composed of separate parts d^3, said sleeve being provided with an oblong head d^4 having pulleys d^5 and d^6 in the opposite ends thereof, said arm being also provided at the opposite end with a yoke g^2, substantially as shown and described.

15. In a clothes-line holder, the combination with a window-frame of a yoke connected therewith and adapted to be swung in a horizontal plane, an arm connected with one end of said yoke by a ball-and-socket joint and provided above and below said joint with a pulley, said arm being also provided in the opposite end with a pulley and means for adjusting said end of said arm laterally with reference to the window-frame, substantially as shown and described.

16. In a clothes-line holder, the combination with a window-frame of a yoke connected therewith and adapted to swing in a horizontal plane, means for adjusting the position of said yoke, an arm connected with said yoke by means of a ball-and-socket joint and provided above and below said joint with a pulley, a pulley detachably connected with the opposite end of said arm and held thereto at a lateral inclination to a vertical plane and a device connected with and adjustable transversely of the window-frame and provided with a clamp which is adapted to swing in a horizontal plane and receive and hold the free end of said arm, substantially as shown and described.

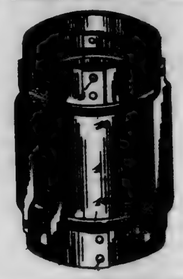
707,848. STAIR-CARPET SECURER. WILLIAM KERNOCHAN, New York, N. Y. Filed Sept. 23, 1901. Serial No. 76,148. (No model.)

Claim.—1. A device of the class described comprising angular brackets or supports, a main outer tube secured thereto and open at one side, and a supplemental inner tube placed in the main outer tube and also open at one side and provided at one side of the opening thereto

with projecting teeth, said inner tube being adapted to be turned and means for locking the tubes together, substantially as shown and described.

2. A device of the class described comprising a main tube open at one side and provided with means for securing it in the corners of a stairway, and a supplemental inner tube placed in the main outer tube and also open at one side and means for securing the inner tube against rotation, substantially as shown and described.

707,849. ASH-RECEPTACLE. JULIUS KRAMER and MAX KRAMER, New York, N. Y. Filed May 16, 1902. Serial No. 107,642. (No model.)



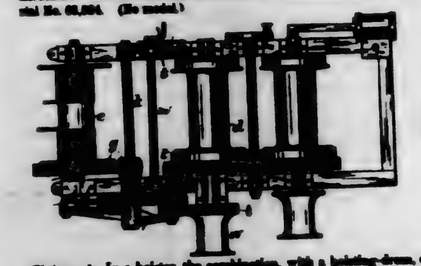
Claim.—In a receptacle of the character specified, the combination with the receptacle proper having a suitable bottom-section, of a pair of protecting collars or flanges, one for each end of said receptacle; suitable means to secure said collars in position; a plurality of reinforcing-sections 9 radially disposed around the body-section and in engagement with said flanges and a plurality of integral reinforcing-tongues carried by the lower collar-section and extending into engagement with the bottom of the receptacle, all combined substantially as specified and for the purpose set forth.

707,850. PHOTOGRAPH-HOLDER. EBENEZER J. G. LAMBERSON and CARL SCHELLER, Hopton, Ill. Filed Nov. 14, 1901. Serial No. 82,669. (No model.)

Claim.—1. The combination with a photograph-receptive means or pocket, of a cord having one end secured to the center of the lower wall of the said means or pocket, and a photograph having an opening in the center of the upper portion thereof through which the cord is loosely passed, a portion of the cord being exteriorly exposed for withdrawing the photograph.

2. The combination with a photograph-receptive means or pocket, of a cord secured at one end in a portion of the pocket or means, and a photograph having an opening in the upper portion thereof through which the cord is passed, the cord having loose movement through the photograph and lying wholly in rear of the latter and adapted to have its free extremity exteriorly exposed.

707,851. BEARING-SWINGING ATTACHMENT FOR HOISTING-ENGINES. ARTHUR LAMBERT, Bernard, N. J. Filed June 7, 1901. Serial No. 63,594. (No model.)



Claim.—1. In a hoister, the combination, with a hoisting-drum, of the means for swinging a boom-derrick, consisting of the swing-drum *e* having the swing-ropes *f*, *f'* wound thereon in reverse directions, a friction-wheel upon the shaft of the hoisting-drum, a lever pivoted upon the frame of the hoister, two friction-wheels geared together and mounted upon such lever, and suitable gearing connecting one of such friction-wheels with the swing-drum.

2. The combination, with a hoisting-drum and drum-shaft, and a grooved friction-wheel *i* upon said drum-shaft, of a swing-drum journaled adjacent to the hoisting-drum and having the swing-ropes *f*, *f'* wound thereon in reverse directions, the shaft *k* journaled between the hoisting-drum and swing-drum and a pair of gear-wheels connecting such shaft with the swing-drum, the cog-wheel *g'* and reverse-lever *j* upon the shaft *k*, the friction-wheels *k'* pivoted upon the reverse-lever, pinions *l* connecting such friction-wheels, one of such pinions engaging the gear-wheel *g'*, and means for operating the reverse-lever to press the friction-wheels at pleasure upon the wheel *i*.

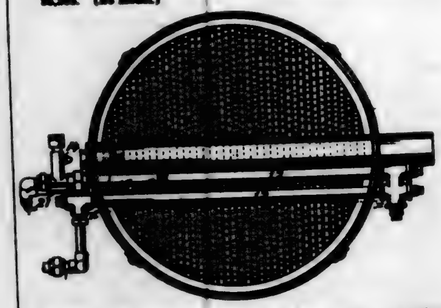
3. The combination, with a hoisting-drum and drum-shaft, and a grooved friction-wheel *i* upon said drum-shaft, of a swing-drum journaled adjacent to the hoisting-drum and having the swing-ropes *f*, *f'* wound thereon in reverse directions, the shaft *k* journaled between the hoisting-drum and swing-drum, a pair of gear-wheels connecting shaft *k* with the swing-drum, the cog-wheel *g'* and reverse-lever *j* upon the shaft *k*, the friction-wheels *k'* pivoted upon the reverse-lever and the pinions *l* connected therewith, the gear-wheel *g'* having one of such pinions engaged therewith, the bell-crank *q* upon the drum-shaft *c* with pin engaging the reverse-lever, the shaft *m'*, the link *p* connecting the shaft *m'* with the bell-crank, and the latch *n* and segment *o* for adjusting and securing such shaft, the whole arranged and operated substantially as herein set forth.

4. The attachment for hoisters having a hoisting-drum provided with the friction-wheel *i*, comprising the frames R, the drum *e* and shaft *k* journaled thereon, a pair of gear-wheels connecting the drum and the shaft *k*, the gear-wheel *g'* and the reverse-lever *j* upon said shaft *k* outside of the frame, the friction-wheels *k'* pivoted upon the reverse-lever, the pinions *l* connecting said friction-wheels, and one of such pinions engaging the gear-wheel *g'*, and means mounted upon the frame R for actuating the reversing-lever, as and for the purpose set forth.

5. The combination, with the hoister having the parallel frames S, a shaft extended across the same, a hoisting-drum upon such shaft, and gearing to drive such drum, of the detachable swing-drum attachment comprising the frames R set at the same distance apart as the frames S to be bolted upon the same timbers or skids, the shaft *c* extended between the frames R and having the swing-drum *e* mounted thereon, a train of gearing connecting the hoisting-drum with the swing-drum and adapted to reduce the speed of the swing-drum, and a reversing-lever to reverse the swing-drum as required, the attachment being constructed separately and adapted for application to such hoisters when first manufactured or after they have been erected and used, substantially as herein set forth.

6. The combination, with a hoisting-drum, of the means for swinging a boom-derrick, consisting of a swing drum or winch having swinging ropes wound thereon in reverse directions, a driving friction-wheel suitably connected to the hoisting-drum to be revolved therewith, and a lever carrying two intermediate friction-wheels geared together to be pressed at pleasure upon the driving friction-wheel, and one of the intermediate friction-wheels connected by suitable gearing to the swing drum or winch, to rotate the same at pleasure in opposite directions, or to wholly disconnect the same from the hoisting-drum.

707,852. HEATING DEVICE FOR HYDROCARBON-BURNERS. GEORGE LAMB, Poughkeepsie, N. Y. Filed Feb. 3, 1902. Serial No. 92,262. (No model.)



Claim.—1. In combination with a hydrocarbon-burner, a closed combustion-chamber within which the burner is situated, a secondary blue-flame burner located within said combustion-chamber, and means for feeding said secondary blue-flame burner with the air used for combustion from within said chamber.

2. In combination a hydrocarbon-burner, a closed combustion-chamber within which the burner is situated, a secondary hydrocarbon-burner located within said chamber, the mixer of said secondary burner drawing its air-supply from within said chamber.

3. In combination with a hydrocarbon-burner, a closed combustion-chamber, a secondary blue-flame burner located within said combustion-chamber, means for supplying the main burner and the secondary burner with fuel, and means for supplying the secondary burner with the air used for combustion from within the combustion-chamber.

4. In combination with a hydrocarbon-burner, vaporizing-tubes for the fuel-supply thereto, a closed combustion-chamber within which said burner and tubes are located, and a secondary blue-flame burner located within said combustion-chamber and under said vaporizing-tubes, and means for supplying said secondary burner with the air used for combustion from within the combustion-chamber.

5. In combination with a hydrocarbon-burner, a closed combustion-chamber within which the burner is situated, a secondary blue-flame burner located within the combustion-chamber, means for independently controlling the supply of fuel to said burners, and means for feeding the secondary burner with the air used for combustion from within the combustion-chamber.

6. In combination an injector-burner for hydrocarbon fuel, a closed combustion-chamber within which the burner is situated and a secondary injector-burner located within the combustion-chamber, the secondary burner drawing its air-supply from within said combustion-chamber.

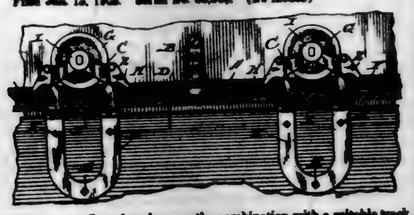
7. An injector-burner adapted to use vapor hydrocarbon fuel, a closed combustion-chamber, a vapor-generator within said combustion-chamber and a secondary injector-burner arranged to keep said generator hot irrespective of the operation of the main burner, said secondary burner drawing its entire air-supply from inside the combustion-chamber of the main burner.

8. A hydrocarbon-burner, a closed combustion-chamber within which the burner is situated, a secondary injector-burner located within the combustion-burner, said secondary burner drawing its fuel-supply from without, and its air-supply from within said combustion-chamber.

9. A hydrocarbon-burner with an inclosing casing, a secondary injector-burner attached to the wall of said casing and having apertures for the admission of air from within said casing.

10. A hydrocarbon-burner with an inclosing casing, a secondary burner attached at one end to the wall of said casing and extended inward and provided with apertures for the admission of air from within said casing, and a fuel-supply pipe adapted to deliver vapor fuel from without the casing into the interior of the secondary burner.

707,858. DOOR-HANGER. WILLIAM LOUDEN, Fairfield, Iowa. Filed Jan. 13, 1902. Serial No. 89,868. (No model.)



Claim.—1. In a door-hanger, the combination with a suitable track, of a hanger-frame carrying a rotary wheel mounted on said track and pivotally secured to a door, the pivotal points of support being laterally out of line with the line of the center of gravity, whereby the lower portion of said frame is free to move toward said line of gravity or to be moved therefrom and the door will tend to move laterally toward said point of support, substantially as described.

2. The combination with a suitable track of a door-hanger comprising two sections having a jointed or pivotal connection between them the upper section carrying a track-wheel adapted to run upon said track, and the lower section adapted to be secured to a door; said upper section being free to assume an angular position relatively to the vertical, and the joint or pivot between the sections being located so that the center of gravity will be out of line with the point of support, whereby the door will tend to move laterally, said lateral movement being facilitated by the angular movement of the upper section.

3. The combination with a track adapted to be secured to a wall, of a door-hanger consisting of two sections having a jointed or pivotal connection between them, the upper section carrying a track-wheel and being adapted to oscillate laterally upon said track, and the lower section being adapted to be secured to a door; said joint or pivot being situated to one side of the point of support of the wheel upon the track, whereby the door will tend to move laterally, said lateral movement being facilitated by the oscillation of the upper section upon the track.

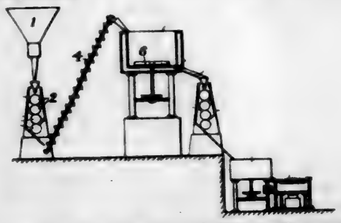
4. The combination with a track adapted to be secured to a wall, of a door-hanger comprising two sections having a jointed or pivotal connection between them, the upper section carrying a trunk-wheel adapted to run centrally on said trunk and to oscillate laterally thereon, and the lower section being adapted to be secured to a door; said joint or pivot being located on a line with one side of said wheel, whereby the door will tend to move laterally, substantially as described.

5. A door-hanger consisting of two separate sections hinged together, the upper section carrying a track-wheel and having a rectangular-shaped loop on each of its lower corners set more or less outside of the periphery of said wheel, and the lower section being adapted to be secured to a door and having hooks or reserved ends on its upper corners adapted to hook into said loops and swing on the pivots formed thereby.

6. In door-hangers a trunk-supporting bracket being L-shaped in its general contour, and having its upper end thickened and rounded off both longitudinally and laterally and fitted with an eye, and its central portions recessed and perforated, its edges fitted with strengthening-flanges, and its lower end flattened, thickened and shouldered, substantially as described.

7. In door-hangers a frame carrying a trunk-wheel to run on a trunk-rail, and having cheek-pieces to support the wheel, the ends of said cheek-pieces being contracted so as to fit together, and having lower extensions which are spread apart and adapted to straddle the trunk-rail, substantially as described.

707,854. PROCESS OF EXTRACTING OILS. ANDERS F. LUNDSTRÖM, Stockholm, Sweden. Filed Nov. 7, 1899. Serial No. 736,169 (No specimens.)



Claim.—The herein-described method of extracting vegetable oils, which consists in first crushing the seed while cold, then heating it, then crushing it a second time, and finally pressing it.

707,855. GRATE. GEORGE HAAS, Akron, Ohio, assignor to the XXth Century Heating and Ventilating Company, Akron, Ohio. Filed Feb. 7, 1902. Serial No. 92,997. (No model.)

Claim.—1. The combination in a grate for furnaces and stoves, consisting of a two-part grate pivotally hinged together, a pivot for the entire grate mounted on one of said portions, an arm mounted on the other portion and means as a swinging bail to vary the inclination of one of said portions.

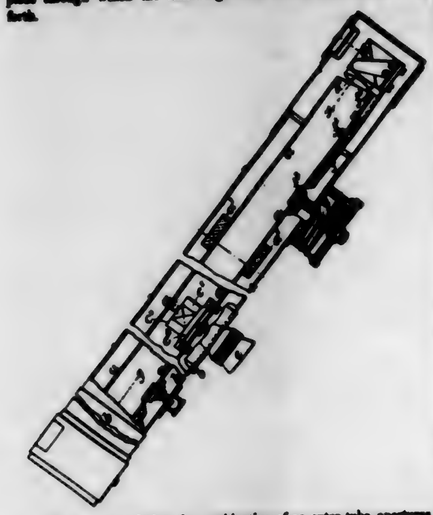
2. The combination in a grate for furnaces and stoves of a two-part grate a lever mounted on one of said parts a swinging bail mounted in said ash-pit arranged when swung in one position to keep said grate level, and when swung in the other direction to lower one of the portions of said grate into an inclined position.

707,856. RANGE-FINDER. ARTHUR H. MARINDIN, Droitwich, England. Filed Mar. 11, 1902. Serial No. 97,718. (No model.)

Claim.—1. In a range-finder, the combination of a case, a fixed reflector at one end of the case, a movable reflector at the other end of the case, a spring carried by the case upon which such movable reflector is mounted, a micrometer-screw acting upon the outer end of the spring, a central combination of erecting-prisms receiving the images from the reflectors, erecting the same, and throwing half of each image at right angles to the case, and an eyepiece through which the half-images are viewed, substantially as set forth.

2. In a range-finder, the combination of a case, a fixed prism at one end thereof, a movable prism at the other end thereof, an objective connected to the adjacent faces of said prisms, a spring carried by the case upon which such movable prism is mounted, a micrometer-screw acting upon the outer end of the spring, a central combination of erect-

ing-prisms receiving the images from the end prisms, creating the same, and throwing half of each image at right angles to the case, and an eye-piece through which the half-images are viewed, substantially as set forth.



3. In a range-finder, the combination of an outer tube, apertures in said outer tube, an inner tube, a fixed prism at one end of said inner tube, a movable prism at the other end of said inner tube, an object-glass connected to the adjacent faces of said prisms, a spring fixed at one end to the inner tube upon which said movable prism is mounted, a weaker portion of said spring projecting therefrom, a micrometer-screw acting upon the outer end of such weaker portion, thereby giving motion to the prism, a combination of prisms receiving the images from the end prisms, creating the same, and throwing half of each image at right angles to the case, and an eyepiece through which the half-images are viewed, substantially as set forth.

4. In a range-finder, the combination of a case, a fixed reflector at one end thereof, an adjustable reflector at the other end thereof, a vertical prism having one end at right angles and one end sloping at an angle of forty-five degrees, a horizontal prism having one flat end and one end sloping at an angle of forty-five degrees, two oppositely-directed right-angle prisms arranged one above another, each having a sloping end at an angle of forty-five degrees, the lower of said right-angle prisms occupying the space between the upper face of the horizontal prism and the inner face of the vertical prism, and an eyepiece adjacent to the combination of prisms, through which the half-images are viewed, substantially as set forth.

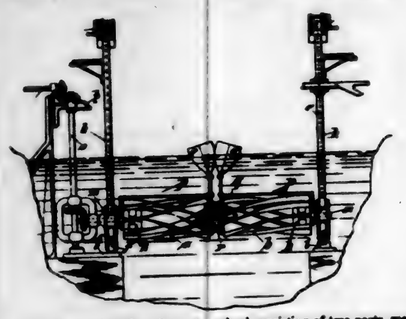
5. In a range-finder, the combination of an outer tube, an inner tube, rubber rings stretched around the inner tube and fitting the outer tube, a fixed prism at one end of the inner tube, an adjustable prism at the other end of the inner tube, a spring fixed at one end of the inner tube upon the same end of which the adjustable prism is mounted, a weaker portion of said spring projecting therefrom, a micrometer-screw acting upon the end of the said weaker portion, thereby giving motion to the prism, a combination of prisms consisting of two rectangular prisms, each having one end at right angles and one end sloping at an angle of forty-five degrees, and two oppositely-directed right-angle prisms each having a sloping end, and an eyepiece adjacent to the combination of prisms, through which the half-images are viewed, substantially as set forth.

707,857. SUBMERGED WATER-WHEEL. Gustav Marburg, Vienna, Austria-Hungary. Filed Apr. 21, 1902. Serial No. 103,803. (No model.)

Claim.—1. The combination of a submerged water-wheel vertically divided in the middle and means for allowing the two parts of the same to swing apart substantially as described.

2. The combination of a water-wheel divided into two parts vertically, a horizontally-disposed stub-shaft to support each part of the same at the outer end, means for coupling the two parts together and means for allowing the supporting-shafts to swing apart in the horizontal plane and separate the two wheel parts substantially as described.

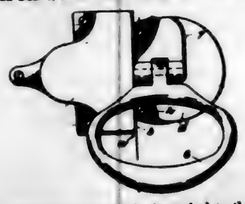
3. The combination of a water-wheel divided into two parts, means for supporting each part of the same at the outer end and floats to entake the inner ends of the same, a coupling to connect the two parts at their adjacent ends and means for allowing the two parts to swing apart horizontally in the manner and for the purpose substantially as described.



4. The combination of a water-wheel consisting of two parts, means for coupling the two parts at their adjacent ends, stub-shafts at the outer ends one to carry each wheel-half, vertically-adjustable bearings for the said stub-shafts in the manner and for the purpose substantially as described.

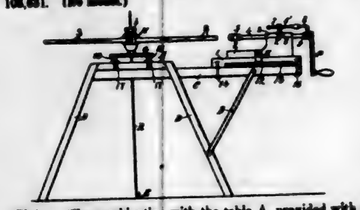
5. The combination of a water-wheel consisting of two parts, means for supporting each part rotatably at its outer end, a coupling to couple the said parts at their adjacent ends and means for adjusting the length of each part to suit currents of different breadths substantially as described.

707,858. DOOR-FASTENER. Aaron B. Meggendall, Anderson, Ind. Filed Dec. 2, 1901. Serial No. 84,641. (No model.)



Claim.—A door-latch having the journal-plate, the catch-plate, having a vertical inner face provided with a recess therein, having an inclined or cam wall, the latch-bolt having the cam designed to engage said recess and cooperate with the cam-wall thereof, said cam having the radial stiffening-rib and the stop-shoulder projecting from the upper face of the cam, said cam having also the handle-lugs, and the handle pivoted to said lugs, said stop-shoulder being designed to engage the vertical face of the catch-plate when the handle is in vertical position and the cam of the latch-bolt is in engagement with the catch-plate, substantially as specified.

707,859. HAND TRIMMING-MACHINE. Roland A. Mills, Oconto, Nebr. Filed Nov. 15, 1900. Renewed Apr. 15, 1902. Serial No. 103,631. (No model.)



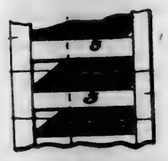
Claim.—The combination with the table A, provided with the supporting-legs B, of the projecting bar C secured below said table A, the adjustable holder *a* secured to said table A, the base 1 secured to said bar C provided with the extending slot 13, the head 2 slidably secured to said base 1, the depending ears 11 secured to said head 2, the bolt 18 passing through said ears and said base, the handle 12 threading upon said bolt 18, the shaft 4 revolubly and slidably held within said head 2, the operating-handle 10 secured to said shaft 4, the collar 9 secured to said shaft 4, the striking bar 8 secured between said collar 9 and handle 10, and the pivoted lever 7, said striking bar being secured to said lever, as and for the purpose set forth.

707,860. FOOT OR HEAD SUPPORTER. David R. Morgan, Phœnix, Ala. Filed May 14, 1902. Serial No. 107,391. (No model.)

Claim.—1. In a portable folding combined foot and head supporter, the combination, with the fixed disk having forks extending from the edge thereof, and the turnable disk, of a bolt connecting the disks and having a head provided with a slot or opening therethrough, an arm having a foot-rest, and a set-screw on the bolt-head whereby the arm is adjustably secured in said slot or opening independent of the disk adjustment.

2. In a portable folding combined foot and head supporter, the combination, with a disk having forks extending from the edge thereof and provided with a set-screw for attaching the disk, and a turnable disk, of a set-bolt having a slotted head extending through the disk by means of which they are clamped together, and an angular arm adjustable in the bolt-head independent of the disk adjustment and having a U-shaped opening.

707,861. WASHBOARD. William R. McPherson and Harry R. Burgs, Tarentum, Pa. Filed Mar. 20, 1902. Serial No. 100,640. (No model.)



Claim.—1. In a reversible washboard, the combination with the frame having recessed side bars, of slats arranged at right angles to the plane of the frame and having their ends received in the said recessed sides, each of said slats having one of its long edges beveled and the other long edge rounded, and blocks arranged between the ends of the said slats.

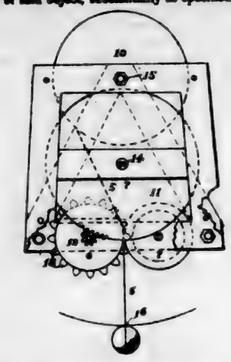
2. In a reversible washboard, the combination of the frame, and slats spaced apart and arranged at right angles to the plane of the frame, each of said slats having one of the long edges rounded, and the opposite edge inclined outwardly and downwardly, substantially as described.

707,862. STANDARD FOR MEASURING HORSES. William H. Sutherland, Louisville, Ky. Filed Dec. 11, 1901. Serial No. 85,569. (No model.)

Claim.—1. In a standard for measuring horses, the combination with a case, of a metal tape perforated on its median line with a row of holes of such a size and shape as to fit snugly the teeth of a pinion which enter said holes; a pinion, having gear-teeth which mesh with said holes of said tape as with a rack, and continuously actuated thereby; a non-adjustable idler articulating with said pinion in such a manner as to keep said tape always in contact with the trough of said pinion; a second pinion, moving with said pinion; a center gear meshing with said second pinion; a center shaft passing through and moving with said center gear; a hand or indicator attached to the outer end of said center shaft; and a dial having graduations indicating hands and fractions of a hand and constituting the entire front cover of the case, substantially as and for the purpose specified.

2. In a standard for measuring horses, the combination of a case, a graduated dial constituting the front cover of said case, a hand or indicator adapted to traverse said dial, a gear-train for actuating said hand or indicator, and an ungraduated metal tape having a median line of holes of such a size and shape as to fit accurately articulating gear-teeth of a pinion, and a suspension-ring on the top of said case, substantially as and for the purpose specified.

3. As a new article of manufacture, a standard for measuring horses, consisting of a case suspended at a predetermined and fixed height above the object the height of which is to be measured, a graduated dial on the surface of said case, a hand or pointer traversing said graduated dial, and a tape perforated on its median line with a row of equidistant holes and adapted to be drawn down to the object to be measured, also counting so as to automatically subtract the distance of said case above the object to be measured from the height of said case, and show immediately on said dial the height of said object, substantially as specified.



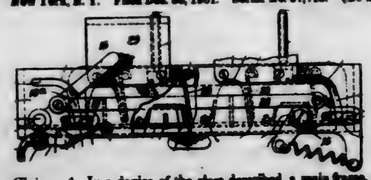
707,863. APPARATUS FOR COOLING OR HEATING LIQUIDS. Jean Heinecker, Offenbach-on-the-Main, Germany. Filed Oct. 12, 1901. Serial No. 78,468. (No model.)

Claim.—1. The combination of the successive batteries of tubes, arranged one above and inclined to the other in opposite directions, and means for delivering a larger quantity of liquid to the upper side and a lesser quantity to the under side of said batteries, as and for the purpose set forth.

2. An apparatus for cooling liquids, consisting of a series of batteries of cooling-pipes arranged one above another, said batteries being inclined successively in opposite directions, and means interposed between the successive batteries partially arresting the liquid flowing from the surface of one battery to that of the next below and delivering a larger quantity of liquid to the upper surface and a lesser quantity to the under surface of each battery, as explained.

3. The combination of successive batteries of tubes, said batteries being arranged one above and inclined to the other and in opposite directions; and troughs having two rows of holes above the successive batteries for distributing liquid over the upper and under sides of said batteries, the capacity of holes for distributing liquid over the upper side exceeding that of those distributing liquid over the under side, as and for the purpose set forth.

707,864. CANDY-COATING DEVICE. Pasquale Pasquilla, New York, N. Y. Filed Dec. 30, 1901. Serial No. 87,715. (No model.)



Claim.—1. In a device of the class described, a main frame, a supplemental frame mounted thereon and vertically and horizontally movable thereon, and means for giving said supplemental frame an oscillating or vibratory movement in a horizontal plane, substantially as shown and described.

2. In a device of the class described a main frame, wires or rods supported therein longitudinally and transversely thereof whereby said frame is divided into separate spaces, each of which is provided with upwardly-directed spring fingers or holders, a supplemental frame mounted in the main frame and vertically and horizontally movable therein, said supplemental frame being also provided over each of said spaces with a spring finger or holder and means for giving the supplemental frame an oscillating movement in a horizontal plane, substantially as shown and described.

3. A device of the class described comprising a main rectangular frame divided into rectangular spaces, devices for holding the candies in said spaces, a supplemental frame mounted in the main frame and vertically and horizontally movable, supplemental candy-holding devices connected with the supplemental frame and provided with downwardly-directed members and laterally-directed members adapted to overlap the candies, means for raising the supplemental frame and moving it in a horizontal plane and devices for giving the supplemental frame an oscillating or vibratory movement in a horizontal plane, substantially as shown and described.

4. A device of the class described comprising a main frame, a supplemental frame mounted therein and movable vertically and in a horizontal plane, candy-holding devices secured in the main frame, supplemental candy-holding devices connected with the supplemental frame, means for raising the supplemental frame, and moving it in a horizontal plane, and devices for giving the supplemental frame an oscillating or vibratory movement in a horizontal plane, substantially as shown and described.

5. A device of the class described comprising a main rectangular frame provided in the bottom thereof with wires or rods arranged longitudinally therein and transversely thereof, whereby said frame is divided into separate spaces, candy-holding devices connected with said wires or rods at three sides of said spaces, a supplemental frame mounted in the main frame over said wires or rods and movable vertically and in a horizontal plane, supplemental candy-holding devices connected with the supplemental frame and comprising members adapted to overlap the candies and downwardly-directed portions or projections adapted to bear on one side thereof opposite one of said holders, means for raising and moving the supplemental frame horizontally and devices for giving said supplemental frame an oscillating or vibratory movement, horizontally, substantially as shown and described.

6. In a device of the class described, a main frame, a supplemental frame mounted therein, and vertically and horizontally movable, means for locking the supplemental frame within the main frame, devices for raising the supplemental frame and moving it horizontally and other devices for giving said supplemental frame an oscillating or vibratory movement, in a horizontal plane, substantially as shown and described.

7. In a device of the class described, a main frame provided with candy-holding devices, a supplemental frame mounted therein and vertically and horizontally movable and devices connected with the supplemental frame and movable irregularly over the candies, whereby said candies are provided with an irregular drip-mark or formation, substantially as shown and described.

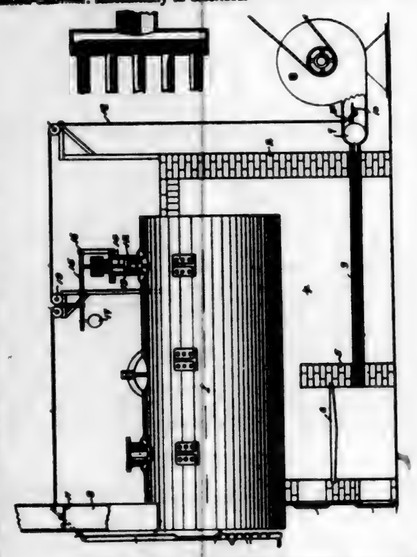
8. In a device for coating candy with chocolate or other material, a frame provided with candy-holding devices, a supplemental frame mounted in said first-named frame and movable vertically and horizontally therein, and devices connected with the supplemental frame and operating in connection with said candy-holding devices for holding the candies in position when the supplemental frame is in its lowermost position, said last-named devices being adapted to disarrange the chocolate covering of the candies and make a mark thereon when the supplemental frame is raised and moved horizontally, substantially as shown and described.

9. In a device for coating candy with chocolate or other material, a frame provided with candy-holding devices and a member mounted in said frame and movable vertically and horizontally therein, said member being provided with devices which operate when said member is moved horizontally to disarrange the chocolate coating of the candies and to form a drip-mark thereon, substantially as shown and described.

707,865. STEAM-BOILER FURNACE. HERMON H. PATTERSON, Norfolk, and JOHN T. BURKE, Omaha, Nebr. Filed Dec. 24, 1901. Serial No. 87,088. (No model.)

Claim.—1. A steam-boiler furnace formed with means for maintaining a pressure within the fire-box and combustion-chamber of the same, comprising a mechanism for forcing air into the ash-pit of the furnace, means for controlling the amount of air forced in, and means for controlling the draft in the chimney the said means cooperating so that when less air is allowed to enter the ash-pit, the means in the chimney will be operated to release the pressure somewhat at that point simultaneously, substantially as described.

2. A mechanism for producing and regulating the pressure within the ash-pit, fire-box and combustion-chamber of a furnace comprising piping for introducing air under pressure into the ash-pit, a valve for controlling the amount of air thus introduced, a check-damper in the chimney-flue, means for operating the valve and damper simultaneously to increase or diminish the pressure maintained within the fire-box and combustion-chamber, substantially as described.



3. Means for producing and maintaining a suitable pressure within a furnace, comprising a series of pipes passing through the combustion-chamber of a furnace and the bridge-wall thereof into the ash-pit, a blower or other air-forcing means for delivering air to said pipes, a gate or valve for controlling the amount of air introduced into the furnace, a check-damper in the chimney-flue of the furnace, means operated by the boiler-pressure and connected with the said gate and the said check-damper so that when the gate is moved to cut off the incoming supply of air, the damper in the chimney-flue will be correspondingly opened to diminish the back pressure upon the draft at the same time thus diminishing the pressure maintained within the fire-box and combustion-chamber of the furnace, substantially as described.

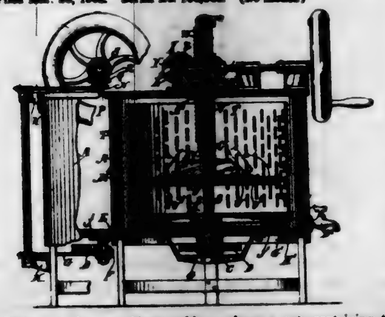
4. A mechanism for producing and regulating the pressure within a furnace comprising a series of pipes passing through the combustion-chamber and bridge-wall of the furnace into the ash-pit, a header for connecting said pipes, a blower for forcing air through the pipes, a gate or valve for controlling the inlet of air to the ash-pit, a check-damper in the smoke-flue of the furnace, a steam-operated pressure mechanism on the boiler of the furnace connected with the said inlet-gate and check-damper for causing the increasing or diminishing of the pressure maintained in the furnace, substantially as described.

5. A pressure producing and maintaining mechanism, comprising means for forcing air into the ash-pit of a furnace, a gate for controlling the same, a check or damper in the smoke-flue, a hand-operated lever for operating said check-damper, a lever operated by the boiler-pressure, cords connecting the said gate and the said check-valve with the said lever so that when the gate is closed the check-damper will be correspondingly opened to control the pressure within the combustion-chamber of the furnace, substantially as described.

707,866. BERRY-BOX. CHARLES B. PROCTOR, Indianola, Iowa. Filed May 6, 1901. Serial No. 58,948. (No model.)

Claim.—A box made of sheet material consisting of a piece or plate of uniform width that has an open slot at one end and the slot widened at its inner end to produce shoulders and a T-head at its other end adapted to enter said open slot and to engage said shoulders and a bottom fitted in the lower portion of the wall and provided with extensions at its ends to overlie parallel sides of the wall and means for detachably connecting the ends of said extensions with the top edge portions of parallel sides of the wall, for the purposes stated.

707,867. WASHING-MACHINE. CHARLES F. SHERLEY, Philadelphia, Pa., assignor of one-half to Charles Kleinknecht, Philadelphia, Pa. Filed Mar. 26, 1902. Serial No. 100,003. (No model.)



Claim.—1. In a washing-machine, a drum, a tub containing the same, a rising-and-falling head in said drum, a shaft connected with said drum, means for rotating said shaft, a sleeve connected with said head, and means for raising said sleeve and permitting the same to drop, said rotary shaft passing freely through said sleeve.

2. In a washing-machine, a drum, a head therein, a sleeve connected with said head, and carrying a rack, a mutilated gear-wheel adapted to gear with said rack, and means for rotating said wheel, whereby said head is raised and permitted to drop, in combination with a shaft which is connected with said drum, and means for rotating said shaft, the latter passing freely through said sleeve.

3. In a washing-machine, a tub, a drum in said tub, a shaft connected with the drum, gearing for operating said shaft, a rising-and-falling head, a sleeve connected with said head, said shaft freely entering said sleeve, means for raising said sleeve and permitting the same to drop, and a lock on the tub adapted to engage with said sleeve.

4. In a washing-machine, a drum, a shaft connected therewith, a rising-and-falling head in said drum, a sleeve connected with said head, means for raising and lowering said head, a boss on the top of the tub, said sleeve being exteriorly of angular form, and said boss having an angular opening receiving said sleeve, and a bolt on the top of the tub, the same being adapted to enter an opening in said sleeve when the latter is in elevated position.

5. In a washing-machine, a tub, a rotary drum therein, a shaft connected with said drum, means for rotating said shaft, a rising-and-falling head in said drum, a sleeve connected with said head, said sleeve freely receiving said shaft, a rack secured to said sleeve, a mutilated wheel engaging said rack, means for rotating said wheel, and a guide on the top of the stationary tub through which said sleeve is vertically passed without capability of rotation.

707,868. CRUPPER. GEORGE SHEPHERD, Newport, Ky. Filed Oct. 22, 1901. Serial No. 79,703. (No model.)

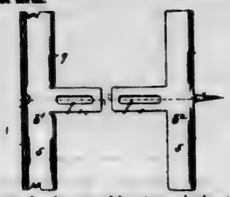
Claim.—1. A crupper having a thin body portion with outwardly-flanged edges, substantially as specified.

2. A crupper having a thin body portion with outwardly-flanged flexible edges, substantially as specified.

3. A crupper consisting of a small piece of leather attached to a larger piece of leather and having the edges of the larger piece bent over those of the smaller piece, to form flanges, substantially as specified.

707,869. LEATHER-STRETCHING CLAMP. JOHN SHEPHERD, Newark, N. J. Filed July 1, 1902. Serial No. 113,594. (No model.)

Claim.—1. The improved grip for stretching leather, comprising two jaws having each a cross-head and shank, the shank being adapted to receive a cord or connection and the cross-head being provided with gripping-teeth, and means for joining the two jaws at their gripping edges, substantially as set forth.



2. The improved grip, comprising two gripping-jaws, one with an eye near its gripping edge and the other with a pointed prong at its gripping edge, substantially as set forth.

3. The improved grip, comprising two jaws having turned gripping edges provided with teeth, one of said jaws being provided with an eye in the line of the gripping-teeth thereof, and the other of said jaws having a prong to enter said eye, and means to hold said jaws together, under tension, substantially as set forth.

4. The improved grip, comprising a pair of separable jaws, each having a shank and cross-head, the latter being provided with gripping-teeth and one of said jaws being provided with an eye at the forward edge and a rib at its rearward edge, and the other of said jaws being provided with a prong to enter the said eye, and the cross-head thereof being adapted to enter between the said rib and the gripping-teeth of the said one jaw first mentioned, substantially as set forth.

707,870. FURNACE. CHARLES F. SMITH, Pittsburg, Pa. Filed Mar. 18, 1902. Serial No. 98,761. (No model.)

Claim.—1. In a furnace, the combination of an outer casing, an inner combustion-chamber, a central pipe communicating therewith, a cold-air pipe, a series of product-chambers in communication with each other, a pipe communicating with the upper of said product-chambers, and with the said central pipe, and the lower chamber being in communication with a flue.

2. In a furnace, the combination of an outer casing, an inner combustion-chamber, a central product-pipe communicating therewith, a cold-air pipe entered in said central pipe communicating with the open air, a series of circular product-chambers communicating with said product-pipe, and a series of product-pipes communicating with said circular product-chambers and said combustion-chamber, substantially as described.

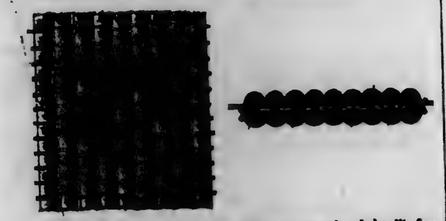
3. In a furnace, the combination of an outer casing, an inner combustion-chamber, a central product-pipe communicating therewith, a cold-air pipe arranged in said central product-pipe and communicating with the open air, a vertically-arranged series of product-chambers provided with transversely-arranged partitions and communicating with each other, and with the said product-pipe, a series of pipes communicating with the lower of the said product-chambers and arranged above the said combustion-chamber, and a flue communicating with one of the said product-chambers.

4. In a furnace, the combination of an outer casing, a hood carried by said casing, distributing-pipes connected to said hood, an interior casing having formed therein a series of circular product-chambers communicating with one another, partitions formed in said chambers, a combustion-chamber, a hood secured to said combustion-chamber, a product-pipe

a cold-air pipe extending in said product-pipe, connections between said product-pipe and circular product-chambers, a series of product-pipes communicating with the lowermost circular product-chamber, all parts being arranged and operating substantially as described.

5. In a furnace, the combination of an outer casing, an inner combustion-chamber, a head secured to the said combustion-chamber, a central product-pipe having its lower end secured to the said head, a central cold-air pipe arranged in the said product-pipe and communicating with the open air, said cold-air pipe having its lower end closed and arranged in the combustion-chamber, and a series of product-chambers communicating with the said central product-pipe.

707,871. WOVEN FABRIC. WILLIAM T. SMITH, Philadelphia, Pa. Filed Feb. 17, 1902. Serial No. 94,054. (No specimens.)



Claim.—1. A woven fabric composed of party-colored chenille face weft-threads, back weft-threads of open yarn, and binding warp-threads uniting the face and back weft-threads, said back weft-threads being large and soft whereby they can be beaten up so closely as to prevent any showing of chenille threads on the back of the fabric, thereby imparting to the latter a matting effect, substantially as specified.

2. A woven fabric composed of party-colored chenille face weft-threads, back weft-threads of open yarn, beaten up so closely as to prevent any showing of chenille threads on the back of the fabric and binding warp-threads uniting the face and back weft-threads, said binding warp-threads being covered and hidden by the chenille for of the face weft-threads and, being of color or colors differing from and contrasting with that of the back weft-threads, whereby a striped effect upon the back of the fabric is produced, substantially as specified.

3. A woven fabric composed of party-colored chenille face weft-threads, back weft-threads of open yarn, similar warp-threads separating the face and back weft-threads, and binding warp-threads uniting the face and back weft-threads, said back weft-threads being large and soft whereby they can be beaten up so closely as to prevent any showing of chenille threads on the back of the fabric, thereby imparting to the latter a matting effect, substantially as specified.

4. A woven fabric composed of party-colored chenille face weft-threads, back weft-threads of open yarn beaten up so closely as to prevent any showing of chenille threads on the back of the fabric, similar warp-threads separating the face and back weft-threads, and binding warp-threads uniting the face and back weft-threads, said binding warp-threads being covered and hidden by the chenille for of the face weft-threads and being of color or colors differing from and contrasting with that of the back weft-threads whereby a striped effect upon the back of the fabric is produced, substantially as specified.

707,872. BICYCLE DRIVING MECHANISM. GEORGE H. SPALDING, Chicago, Ill., assignor of one-half to George Hodenpyle, Chicago, Ill.; Lois L. Spalding administratrix of said George H. Spalding, deceased. Filed Mar. 20, 1902. Serial No. 98,763. (No model.)

Claim.—1. In a bicycle, the combination with the frame, the speed-gearing frame, the crank-shaft or prime-motor shaft having journal-bearings in the speed-gearing frame, said gearing-frame being made rigid at the ends of said journal-bearings with the bicycle-frame; a gearing-case having journals encompassing said journal-bearings of said shaft and encompassed at its ends by the terminals of the bicycle-frame; the speed-train having its first wheel fixed on the crank-shaft and its last wheel concentric with said shaft and fixed to said case, said gearing-case being exteriorly constructed to operate as a wheel communicating power to the drive-wheel.

2. In a bicycle, in combination with the main frame, a speed-gear frame; a two-part gearing-case which may be parted to admit the speed-gear and train, the case having hollow trunnions and being journaled thereby in the main frame; the speed-gearing frame also having hollow trunnions, said trunnions extending through the hollow trunnions of the case, and coupling-sleeves extending between the respective trunnions of the case and the speed-gear frame, each coupling-sleeve having flanges at the outer ends extending past the ends of the hollow trunnions of the case to connect the speed-gearing frame non-rotatably with the fork-arms of the crank-hanger.

3. In a bicycle, in combination with the main frame having a bifurcated crank-hanger, a speed-gear frame, a two-part gearing-case which may be parted to admit the speed-gear frame and train, the case having hollow trunnions by which it is journaled in the arms of the crank-hanger, and the speed-gearing frame having also hollow trunnions extending through the hollow trunnions of the case, and coupling-sleeves extending between the respective trunnions of the case and the speed-gear frame, each coupling-sleeve having flanges at the outer ends extending past the ends of the hollow trunnions of the case to connect the speed-gearing frame non-rotatably with the fork-arms of the crank-hanger.

4. In combination with a bicycle-frame, a speed-gear case having hollow trunnions, which are journaled in the bicycle-frame; a speed-gear frame within the case; the prime-motor shaft journaled in the speed-gear frame and extending out through the hollow trunnions of the case, a speed-gear train having its prime wheel fixed on the shaft between the bearings of the latter in the speed-gear frame, and the last wheel rigid and concentric with the case; and couplings which connect the bicycle-frame, outside the case-bearings non-rotatably with the speed-gear frame.

707,878. GAUNTREE. GEORGE H. STORMER, Washington, D. C. Filed Oct. 5, 1901. Serial No. 77,894. (No model.)

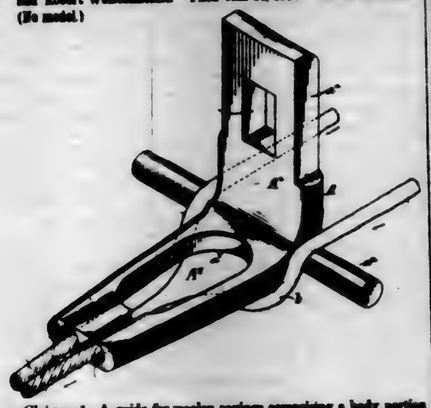
Claim.—1. In combination with a canteen, of a device fitting in the neck thereof, consisting of a stopper having an opening with grooved sides having a closed upper end provided with perforations fitting in said opening, a rim upon the exterior of said tube above the stopper, a vent-cap surrounding said tube and held upon the stopper by the rim of the tube, and a filtering-cup detachably connected to the lower end of the tube.

2. In combination with a canteen of a device fitting in the neck thereof, consisting of a stopper having a central opening with grooved sides, a tube fitting in said opening and allowing said grooved sides to provide a series of vertical channels therearound, a cap mounted upon said tube provided with a series of perforations to fit on the stopper, and means for filtering the water carried at the lower end of the tube.

3. In combination with a canteen, of a device fitting in the neck thereof consisting of a stopper provided with a central opening, a tube fitting in said opening in such a manner so as to provide a series of vent-channels about the tube, a rim carried by said tube, a vent-cap fitting upon said tube and over the stopper, and a detachable filtering means carried by the lower end of the tube.

4. In combination with a canteen, of a device fitting in the neck thereof consisting of a stopper having a channel with grooved sides therethrough, a tube fitting in said channel in such a manner as to cause the grooves to provide a series of air-vents therearound, an exterior rim carried by the tube above the stopper, a vent-cap carried by the tube below the rim to fit over the vent-openings of the stopper, and a filtering means detachably connected to the lower end of the tube.

707,874. ROVING-GUIDE. FREDERICK STEVENS, Philadelphia, Pa., assignor to Thomas Wolstenholme, Sons & Company, Philadelphia, Pa., a firm composed of Thomas Wolstenholme, Albert Wolstenholme, and Robert Wolstenholme. Filed Jan. 14, 1902. Serial No. 89,763. (No model.)



Claim.—1. A guide for woolen rovings comprising a body portion having an opening provided with a passage or passages extending therefrom, with means other than said passages for imparting a false twist to strands of material passing through the same, substantially as described.

2. A guide for woolen rovings comprising a body portion having an opening and a plurality of substantially straight passages extending from said opening, with means other than said passages for imparting a false twist to strands of material passing through the same, substantially as described.

3. A guide for woolen rovings comprising a body portion having an opening and a plurality of passages extending from said opening, with projections on the body portion whereby a false twist is given to strands of material prior to their entrance into said passages, substantially as described.

4. A guide for woolen rovings comprising two portions joined together, one portion having through it an opening, and a plurality of passages extending from the side walls of said opening through the body of the guide to the outer edge thereof, means other than said passages for imparting a false twist to strands of material passing through the same, the second portion of said guide being constructed to be engaged by a securing device, substantially as described.

5. A guide for woolen rovings comprising two portions joined together, one portion having through it an opening and a plurality of passages extending from said opening, the other portion having an opening for the passage of a securing device, and projections formed integral with the guide and extending in a plane substantially parallel to one of the portions thereof, substantially as described.

6. A guide for woolen rovings comprising two portions joined together along one edge, an opening through one of the portions, two passages extending from one side of said opening to the end of the guide and two substantially cylindrical bars projecting at right angles to the said passages, the other portion of the guide having means for attaching it to a support, substantially as described.

7. A guide for woolen rovings comprising a body portion having an opening provided with a passage or passages extending therefrom and a projecting portion whereby a false twist is imparted to strands of material passing through the same, substantially as described.

707,875. SAVINGS-BANK. CHARLES B. SELWELL, Philadelphia, Pa. Filed Apr. 14, 1902. Serial No. 102,904. (No model.)

Claim.—1. In a bank or money-receptacle, a tripartite inclosing case, comprising an upper hemispherical part, an intermediate spherical zone and a lower spherical segment; means to join the hemispherical and zone parts at their junction, to prevent rotating movement; and means to join the zone and segment and permit the segment to rotate on the zone.

2. In a bank or money-receptacle, a tripartite inclosing structure, the lower member of which is rotatable on the intermediate member, a coin-receiving opening in the upper member, and a guard-plate within and extending toward the center of the receptacle.

3. In a savings-bank, a tripartite spherical receptacle, an upper part having a slot therein, an angular chute removably secured therein; an intermediate part, a bottom for this part, and means entering the bottom, upwardly passing, and engaging the chute and adapted to hold all of the aforesaid parts to each other in their proper positions.

4. In a savings-bank, a tripartite receptacle having a slot leading into the receptacle, a chute, a dovetail on the chute fitting into the receptacle, a screw inserted into the intermediate part of the receptacle and means for its entering the chute to draw the dovetail aforesaid in its seat, and the upper and intermediate parts of the receptacle to each other.

5. In a savings-bank, a tripartite spherical receptacle, comprising a hemispherical part, a spherical zone and a spherical segment, means to secure the hemispherical and zone parts to each other, and means to uncover the securing attachment when the bank is to be opened, and to cover it when the bank is locked.

6. In a savings-bank, a tripartite inclosing case, the intermediate and lower parts pivotally united to allow the lower part to rotate on the intermediate part; flat seats for the intermediate and lower parts at their junction, and having grooves within each seat.

7. In a savings-bank, a tripartite receptacle, the intermediate and lower parts being rotatably united, and at the junction having their faces closely approaching in parts and provided with radial and diagonal grooves which correspond in rotative direction.

8. In a savings-bank, an intermediate part, a lower part, pivotal connection for the lower to the intermediate part each part having a series of grooves and balls in the grooves.

9. In a savings-bank, a tripartite receptacle, the intermediate and lower parts pivotally joined; the intermediate part having having an outer circular channel, a radial groove joining the channel, a diagonal groove joining the channel, a radial groove having a circular groove joined thereto; the lower part having radial grooves and a diagonal groove, said grooves coinciding with similar grooves in the intermediate part; a pocket in the lower part in communication with the inner circular groove of the intermediate part; a ball in each radial groove, a ball in the diagonal groove, and a ball in the inner circular groove and adapted to enter the pocket aforesaid.

10. In a savings-bank, a tripartite receptacle, the lower part pivotally secured below the intermediate part; a screw seated in the intermediate part, upwardly reaching and entering the upper and intermediate parts to each other; an opening in the lower part through which the screw is turned; a series of grooves being formed in the intermediate part and in the lower part; balls in the grooves and resting in the groove to permit the rotation of the lower part on the intermediate part when in certain positions, and permit access to the screw aforesaid, and when placed in certain other positions to lock the lower part, prevent its rotation, and conceal the screw aforesaid.

11. In a coin-receptacle, a hollow structure in three principal parts, the upper and intermediate parts being adapted to receive and hold coins, the lower part adapted to rotate on the intermediate part; with a series of grooves in the intermediate and lower parts; balls in the grooves, and means to support the structure in an upright position.

707,876. GARMENT-SUPPORTER. JAMES SHERMAN, New York, N. Y. Filed June 3, 1901. Serial No. 62,857. (No model.)

Claim.—1. In a garment-supporter, the combination of a frame having its opposite sides nearer together at one point than at another, a tongue connected with said frame and having a longitudinal sliding movement on the same, and provided at its free end with a yielding hook consisting of two disks of yielding material secured together and to the tongue, and having their edges extending beyond the side edges of the tongue for engagement with the sides of the frame only at its narrow portion, and said tongue and hook also having a free radial movement through the frame whenever the edges of the disks are out of engagement with the nar-

tracted portion of the frame, whereby either side of the supporter may be readily applied to a portion of a garment with the latter caught and held between the edges of the disks and contracted sides of the frame.

2. In a garment-supporter, the combination of a frame having its opposite sides nearer together at one point than at another, a tongue connected with said frame and having a longitudinal sliding movement on the same, and provided at its free end with a yielding knob consisting of two disks of yielding material secured together and to the tongue and having a groove between said edges and said edges extending beyond the side edges of the tongue for engagement with the sides of the frame only at its narrow portion, and said tongue and knob also having a free radial movement through the frame whenever the edges of the disks are out of engagement with the contracted portion of the frame, whereby either side of the supporter may be readily applied to a portion of a garment with the latter caught and held between the edges of the disks and contracted sides of the frame.

3. In a garment-supporter, the combination of a frame having its opposite sides nearer together at one point than at another, a cross-bar connected to said frame and said cross-bar and frame constructed to have a sliding movement relative to each other, and longitudinally with respect to the frame, a tongue attached to said cross-bar, and provided at its free end with a yielding knob having its edges extending beyond the side edges of the tongue for engaging with the sides of the frame only at its narrow portion, and said tongue and knob also having a free radial movement through the frame whenever the knob is out of engagement with the contracted portion of the frame, whereby either side of a supporter may be readily applied to a portion of a garment with the latter caught and held between the knob and contracted sides of the frame.

4. In a garment-supporter, the combination of a frame having its opposite sides nearer together at one point than at another, a cross-bar connected to said frame, and said cross-bar and frame constructed to have a sliding movement relative to each other and longitudinally with respect to the frame, a tongue attached to said cross-bar and provided at its free end with a yielding knob having curved edges extending beyond the side edges of the tongue for engagement with the sides of the frame only at its narrow portion, and said tongue and knob also having a free radial movement through the frame whenever the edges of the disks are out of engagement with the contracted portion of the frame, whereby either side of the supporter may be readily applied to a portion of a garment with the latter caught and held between the edges of the disks and contracted sides of the frame.

5. In a garment-supporter the combination of a frame with its opposite sides nearer together at one point than at another, a cross-bar connected to said frame, and said cross-bar and frame constructed to have a sliding movement relative to each other and longitudinally with respect to the frame, a tongue attached to said cross-bar and provided at its free end with a yielding knob consisting of two disks of yielding material secured together and to the tongue, and having their edges extending beyond the side edges of the tongue, and said tongue and disks having a free radial movement through the frame, whenever the edges of the disks are free from engagement with the contracted portion of the frame, whereby either side of the supporter may be readily applied to a portion of a garment with the latter caught and held between said edges of the disks and the contracted sides of the frame.

6. In a garment-supporter, a knob member for engagement with the loop or contracted member, said knob member consisting of two rigid disks covered with yielding material and concentrically secured together substantially as and for the purposes set forth.

7. In a garment-supporter, the combination with a tongue member, of two yielding disks secured together and to said tongue member, and said disks having their edges extending beyond the side edges of the tongue, all as and for the purposes set forth.

8. In a garment-supporter, the combination with a tongue member, of two yielding disks concentrically secured together and to said tongue member, and said disks having their edges extending beyond the side edges of the tongue, all as and for the purposes set forth.

9. In a garment-supporter the combination with the tongue member, of two disks secured to the tongue member on opposite sides of the same, and concentric with each other, all as set forth.

10. In a garment-supporter the combination with the tongue member, of two yielding disks secured to the tongue member on opposite sides of the same, and concentric with each other, all as set forth.

11. In a garment-supporter a knob member for engagement with the loop or contracted member, said knob member consisting of two rigid disks covered with rubber and concentrically secured together, substantially as and for the purposes set forth.

12. In a garment-supporter, the combination of a frame having its opposite sides nearer together at one part than at another, a cross-bar connected to said frame, and said cross-bar and frame constructed to have a sliding movement relative to each other and longitudinally with respect to the frame, a tongue attached to said cross-bar, and having a free radial movement on said bar, and two yielding disks secured opposite to each other and to the tongue on opposite sides of its free end, and extending beyond said tongue, whereby a portion of the garment may be readily applied to and be caught and held in the recess between the edges of said disks and between it and the contracted sides of the frame.

13. In a garment-supporter, the combination of a frame having its opposite sides nearer together at one part than at another, a cross-bar connected to said frame, and said cross-bar and frame constructed to have a sliding movement relative to each other and longitudinally with respect to the frame, a tongue attached to said cross-bar, and having a free radial movement on said bar, and two rubber disks secured opposite to each other and to the tongue on opposite sides of its free end, and extending beyond said tongue, whereby a portion of the garment may be readily applied to and be caught and held in the recess between the edges of said disks and between it and the contracted sides of the frame.

14. In a garment-supporter, the combination of a frame having two of its opposite sides nearer together at one point than at another, a tongue having a parallel movement and a transverse radial movement relative to the frame, and two yielding disks secured opposite to each other and to the tongue on opposite sides of its free end, and extending beyond said tongue, whereby a portion of the garment may be readily applied to and be caught and held in the recess between the edges of said disks, and between it and the contracted sides of the frame.

707,877. CLASP OR BUCKLE. JEROME SILBERGHEIM, New York, N. Y. Filed June 12, 1901. Serial No. 64,314. (No model.)

Claim.—1. A clasp or buckle comprising two attachable and detachable members, one of which is provided with two opposite walls meeting the other part of the member, and the other member having edges struck up from the same and extending above the surface of said member and corresponding with the inner sides of said walls of the other member whereby the two members may be united, with said edges of one closely held by the inner walls of the other.

2. A clasp or buckle comprising two attachable and detachable members one of which is provided with a hook-tongue, extending above the surface of said member and the other member having a sleeve for surrounding and for engagement with the tongue when said members are attached, and said sleeve provided with a bearing-surface at or near its free end for the free end of said tongue, and the side edges of said tongue corresponding with the inner walls of said sleeve, whereby the two members may be united, with the side edges of the tongue closely held by the inner walls of the sleeve.

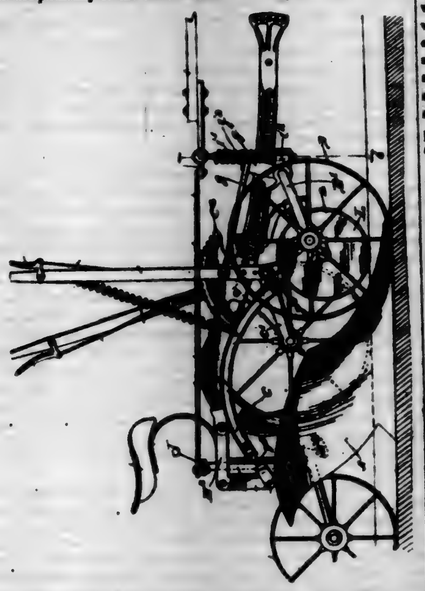
3. A clasp or buckle comprising two attachable and detachable members one of which is provided with a hook-tongue, extending above the surface of said member and the other member having a sleeve for surrounding and for engagement with said tongue when said members are attached, and said sleeve provided with a bearing-surface at or near its free end for the free end of said tongue, and the side edges of said tongue corresponding with the inner walls of said sleeve, whereby the two members may be united, with the side edges of the tongue closely held by the inner walls of the sleeve.

4. A clasp or buckle comprising two attachable and detachable members one of which is provided with a spring hook-tongue, extending above the surface of said member and the other member having a sleeve for surrounding and for engagement with said tongue when said members are attached, and the side edges of said tongue corresponding with the inner walls of said sleeve, whereby the two members may be united, with the side edges of the tongue closely held by the inner walls of the sleeve.

707,878. PLOW. SILVUS H. THOMAS, Davenport, Iowa, assignor to the Imperial Manufacturing Company, Davenport, Iowa, a Corporation of Iowa. Filed Oct. 29, 1901. Serial No. 79,612. (No model.)

Claim.—1. A wheeled plow comprising a suitable plow and plow-beam, a plurality of crank-axles, furrow and land side wheels mounted on said axles, a rear caster-wheel, a shifting connection between the caster-wheel and plow-beam, a lever connected and arranged for simultaneously rotating both of said axles and operating said shifting connection, so as to cause a bodily rise and fall of the plow, and a second lever connected and arranged for operating said land-side wheel independently of the others.

2. A frameless high-lift sulky-plow, comprising a suitable plow and plow-beam, a plurality of crank-axles, furrow and land side wheels mounted on said axles, a rear caster-wheel, a shifting connection between said rear wheel and said plow-beam, a lever mounted on one of said axles and arranged for simultaneously rotating both axles and operating said shifting connection, and a second lever arranged for operating said land-side wheel independently of the other wheels.



3. A wheeled plow comprising a suitable plow and plow-beam, a pair of crank-axles arranged one in front of the other, a hand-lever secured rigidly to one crank-axle, an arm rigidly secured to the other crank-axle, a connecting-rod extending between said arm and said lever, a land-side wheel mounted on this axle to which the said lever is rigidly secured, a furrow-side wheel mounted on the axle to which the said arm is secured, a rear supporting-wheel capable of bodily shift or movement relatively to the plow or plow-beam, and suitable connection between said lever and said rear supporting-wheel, the said lever being thereby operative to cause both the front and rear supporting-wheels to shift or move relatively to the plow or plow-beam for the purpose of either raising or lowering the plow, substantially as described.

4. A wheeled plow comprising a suitable plow, a beam, a pair of crank-axles, wheels on said axles, a hand-lever secured rigidly to one of said crank-axles, a crank-arm on the other axle, a rod connecting said arm with said lever, a wheeled structure for supporting the rear end of the plow and beam, a rack bolted to the beam, and a locking device on the lever adapted to engage said rack, substantially as described.

5. In a wheeled plow, the combination of a suitable plow and beam, a pair of crank-axles arranged one in front of the other at the forward portion of the plow-beam, furrow and land side wheels on said axles, a trailing caster-wheel adapted and arranged to support the rear end of the plow and beam, a lever rigidly secured to the land-side axle and connected and arranged for simultaneously controlling or adjusting all three wheels, and a second lever loosely mounted upon the land-side axle and adapted to independently shift or adjust the land-side wheel, substantially as described.

6. In a wheeled plow, the combination of a suitable plow and beam, a pair of crank-axles, wheels on said axles, a lever suitably connected and arranged for rocking or rotating said axles, a rear supporting-wheel having a shifting connection with said plow-beam, suitable connection between said lever and rear supporting-wheel, and a spring arranged to connect said lever with said plow-beam, the tension of the spring tending to draw the lever back and thereby shift or adjust all the supporting-wheels relatively to the plow and beam in such manner as to raise the plow from the ground, substantially as described.

7. In a wheeled plow, the combination of a suitable plow and beam, a pair of crank-axles, a pair of levers mounted on one axle and adapted and arranged for rocking said axles, supporting-wheels on said axles, a rack secured to the plow-beam and adapted to engage a locking device on one of said levers, a segmental rack rigid with the axle on which the said levers are mounted and adapted to engage a locking device on the other lever, and a rear trailing wheel having suitable connection with one of said levers, substantially as described.

8. In a wheeled plow the combination of a suitable plow and beam, a pair of crank-axles, supporting-wheels on said axles, a rear supporting-wheel for supporting the rear end of said plow and beam, a lever rigid with one of said axles, a rack secured to the plow-beam, a manually-operated locking device mounted on said lever and adapted to engage said rack, suitable connection between said axles adapted to cause the axles to rotate in unison, and suitable connection between said lever and said rear supporting-wheel, the lever thereby being operative to cause all the supporting-wheels to shift or move relatively to the plow and plow-beam for the purpose of either raising or lowering the plow, substantially as described.

9. In a wheeled plow, the combination of a suitable plow and beam, forward supporting-wheels, a rear trailing caster-wheel, a suitable sleeve for the spindle of said caster-wheel, and swinging arms for connecting the said sleeve with the rear portion of said plow-beam, said swinging arms being arranged in pairs, one at each side of the beam and the sleeve, and the swinging connection thereby provided being in the nature of a parallel movement for permitting relative shift or movement on the part of said caster-wheel and the said plow and beam, substantially as described.

10. In a wheeled plow, the combination of a suitable plow and beam, a plurality of crank-axles, forward supporting-wheels, mounted on said axles, a rear trailing caster-wheel, a suitable sleeve providing a bearing for the spindle of said caster-wheel, an upper pair of swinging arms arranged one at each side of the said sleeve and adapted to connect the latter with the rear portion of the plow-beam, a lower and similar pair of swinging arms adapted and arranged to connect the lower portion of said sleeve with the plow-beam, the members of each pair of arms in this way being arranged one at each side of the sleeve and the beam, and constituting a parallel movement for permitting relative shift or movement on the part of said plow and caster-wheel, substantially as described.

11. In a wheeled plow, the combination of a suitable plow and beam, a plurality of crank-axles, forward supporting-wheels mounted on said axles, a rear trailing caster-wheel for supporting the rear end of said plow and beam, a suitable sleeve adapted to provide a bearing for the spindle of said caster-wheel, an upper pair of swinging arms arranged at each side of the sleeve and adapted to connect the latter with the plow-beam, a lower and similar pair of arms arranged one at each side of the sleeve and adapted to connect the same with the plow-beam, a swinging hand-lever, an arm projecting downwardly from the rear end of one of the upper swinging arms, the swinging arm thus provided with a downwardly-projecting extending arm constituting a bell-crank, and a suitable rod for connecting said lever with the lower end of said downwardly-projecting arm of the bell-crank, the lever thereby being operative to exert a pull upon said rod for the purpose of causing the caster-wheel to shift relatively to the plow and beam for the purpose of lifting and raising the plow from the ground, substantially as described.

12. In a wheeled plow, the combination of a suitable plow and beam, a pair of crank-axles adapted to provide suitable spindles for the land-side and furrow-side wheels, two hand-levers for causing relative shift on the part of said wheels and also for causing simultaneous shift on the part of each wheels relatively to the plow and beam, a rear trailing or supporting wheel adapted and arranged to support the rear end of said plow and beam, a bell-crank forming part of a swinging connection between said rear supporting-wheel and the plow-beam, a pitman or connecting rod adapted to serve as a pull-rod for connecting one of said levers with said bell-crank, the lever thus connected with the bell-crank being also suitably connected with both crank-axles, whereby all three supporting-wheels may be controlled or adjusted through the medium of a single lever, and the other of said levers being suitably mounted and arranged for independent movement for the purpose of adjusting the land-side wheel independently of the balance of the machine, substantially as described.

13. In a wheeled plow, the combination of a suitable plow and beam, a pair of crank-axles, supporting-wheels on said axles, a lever on one of said axles, a crank-arm mounted upon the other of said axles and provided with a fastening device which permits longitudinal or end movement on the part of said axle relatively to the crank-arm, a rod or the like for connecting said lever with said crank-arm, a wheeled structure for supporting the rear part of said plow and beam, and connecting means whereby said lever is operative to simultaneously adjust or shift all the supporting-wheels relatively to the plow and beam for the purpose of either raising or lowering the plow, substantially as described.

14. In a wheeled plow, the combination of a suitable plow and beam, forward supporting-wheels, a wheeled structure for supporting the rear end of said plow and beam, and a turntable adapted and applied for causing relative shift on the part of said plow and said wheeled sup-

porting structure, so as to tilt the plow forward and thereby prevent its heel from dragging in the furrow, substantially as described.

707,879. SULKY-PLOW. SAMUEL H. TYRRELL, Davenport, Iowa, assignor to the Implement Manufacturing Company, Davenport, Iowa, a Corporation of Iowa. Filed Jan. 27, 1902. Serial No. 91,314. (No model.)

Claim.—1. In a wheeled plow, the combination of a suitable plow and plow-beam, a crank-axle journaled in a bearing on said plow-beam, a land-side wheel mounted on said axle, a furrow-side wheel having a shifting connection with the said plow-beam, a rear caster-wheel having a shifting connection with said plow-beam, a swinging hand-lever secured to said crank-axle, and suitable connections between said lever and the furrow-side wheel and the caster-wheel, the said lever thereby being operative to simultaneously control all of said wheels, so as to bodily raise and lower said plow.

2. In a wheeled plow, the combination of a suitable plow and plow-beam, a crank-axle journaled in a bearing on said plow-beam, a supporting-wheel on said crank-axle, an upright spindle, a supporting-wheel carried by said spindle, a rear caster-wheel, a sliding connection intermediate of said plow-beam and said spindle, a hand-lever secured to said crank-shaft, suitable connections between said lever and said caster-wheel, suitable connections between said lever and said spindle, the said lever thereby being operative to simultaneously control said wheels, so as to bodily raise and lower said plow.

3. In a wheeled plow, the combination of a suitable plow and plow-beam, a plurality of supporting-wheels all capable of movement relatively to the plow and plow-beam, a crank-axle upon which one of said wheels is mounted, a crank-axle bearing secured to said plow-beam, a hand-lever rigidly secured to said crank-axle, and suitable connections between the lever and the other supporting-wheels, the said lever thereby being operative to simultaneously control all of said wheels, so as to bodily raise and lower the plow.

4. In a wheeled plow, the combination of a suitable plow and plow-beam, a crank-axle journaled in a bearing on said beam, a land-side wheel on said crank-axle, a vertical spindle, a furrow-side wheel carried by said spindle, a sliding connection intermediate of said plow-beam and said spindle, a rear caster-wheel, upper and lower links connecting said caster-wheel with the rear portion of said plow-beam, a lever rigidly secured to said crank-axle, a link and rock-shaft for connecting said lever with the upper end of said spindle, a link and a bell-crank for connecting said lever with the rear caster-wheel, the said lever thereby being operative to simultaneously control all of said wheels, so as to bodily raise and lower said plow.

5. In a frameless high-lift wheeled plow, the combination of a suitable plow and plow-beam, a furrow-side wheel having a shifting connection with said plow-beam, a crank-axle journaled in a bearing on said plow-beam, said crank-axle being arranged back of said furrow-side wheel, a land-side wheel mounted on said crank-axle, a rear caster-wheel having a shifting connection with the rear upright portion of the plow-beam, a lever rigidly secured to said crank-axle, suitable connection between said lever and said caster-wheel, suitable connection between said lever and the furrow-side wheel whereby all three wheels may be controlled by said lever, and a second lever for independently controlling the said land-side wheel.

6. In a wheeled plow, a suitable plow and plow-beam, a rear caster-wheel having a stem, a bearing in which said stem is free to turn, upper and lower links connecting said bearing with said plow-beam, said links being arranged in pairs at opposite sides of the plow-beam, a land-side wheel and a furrow-side wheel having shifting connections with the plow-beam, a swinging lever having suitable connections with both the furrow and the land side wheels, and a pull-rod connecting said lever with one of said links, the said lever thereby being operative to simultaneously control all of said wheels, so as to bodily raise and lower the plow.

7. In a wheeled plow the combination of a suitable plow and plow-beam, forward supporting-wheels having shifting connections with the plow-beam, a rear caster-wheel provided with a stem, a bearing in which said stem is free to turn, links connecting said bearing with said plow-beam, said links being arranged in upper and lower pairs one at each side of the plow-beam, and a lever connected and arranged for causing relative shift between the plow-beam and the said bearing, so as to raise or lower the rear end of the plow-beam.

8. In a wheeled plow the combination of a suitable plow and plow-beam, forward supporting-wheels, a rear caster-wheel provided with a stem, a bearing in which said stem is free to turn, upper and lower links connecting said bearing with said plow-beam, one of the upper links being constructed to serve as a bell-crank, a swinging lever, and a pull-rod arranged to connect said bell-crank with said lever, the pull exerted by the said rod upon the bell-crank operating to lift the plow.

9. In a wheeled plow, the combination of a suitable plow and plow-beam, a furrow-side wheel having a shifting connection with the plow-beam, a crank-axle journaled in a bearing on said plow-beam, a land-side wheel on said crank-axle, a rear caster-wheel having a stem, a bearing in which said spindle is free to turn, upper and lower links connecting said bearing with said plow-beam, one of the upper links being adapted to serve as a bell-crank, a swinging lever rigidly secured to said crank-shaft, a pull-rod arranged to connect said lever with said bell-crank, and a link and a rock-shaft forming medium of connection between said lever and the said furrow-side wheel, the said lever thereby being operative to simultaneously control all of said wheels, so as to bodily raise and lower the plow.

10. In a wheeled plow, the combination of a suitable plow and plow-beam, forward supporting-wheels having shifting connections with the plow-beam, a rear caster-wheel having a shifting connection with the plow-beam, a swinging lever having suitable connection with the forward supporting-wheels, and an arched pull-rod arranged to connect the lower end of said lever with the connecting means between the caster-wheel and the plow-beam, the said lever thereby being operative to simultaneously control all of said wheels, and to raise and lower the plow.

11. In a wheeled plow, the combination of a suitable plow and plow-beam, forward supporting-wheels having shifting connections with said plow-beam, a rear caster-wheel having a shifting connection with said plow-beam, a swinging lever suitably connected with said forward supporting-wheels, a pull-rod serving as medium of connection between the lower end of said lever and the said caster-wheel, and a spring arranged and connected to exert a pull upon said pull-rod, the said lever thereby operating to simultaneously control all of said wheels, so as to raise and lower the plow-beam, the pull of the said spring existing in raising the plow.

12. In a wheeled plow, the combination of a suitable plow and plow-beam, forward supporting-wheels, a rear caster-wheel having a shifting connection with said plow-beam, a swinging hand-lever connected and arranged to cause relative shift or movement between said caster-wheel and the plow and plow-beam, and a spring connected and arranged to assist said lever in causing relative shift between the caster-wheel and the plow beam, the spring and lever cooperating to lift the plow.

13. In a wheeled plow, the combination of a suitable plow and plow-beam, supporting-wheels whereof one is a land-side wheel, a crank-axle journaled in a bearing on the said plow-beam, said crank-axle being made in two sections, said land-side wheel being mounted on the outer of said sections, a rank rigid with the section of the axle journaled in said bearing, a coupling holding the two sections end to end, the coupling being rigid with the outer section and arranged to turn on the inner section, a lever rigid with said coupling and a locking device carried by said lever and adapted to engage said rank, whereby the land-side wheel can be adjusted independently of the balance of the machine.

14. In a wheeled plow, the combination of a suitable plow and plow-beam, a plurality of supporting-wheels whereof one is a land-side wheel, a crank-axle upon which said land-side wheel is mounted, said crank-axle being composed of two sections, a segmental rank rigid with one section, a coupling holding the two sections end to end, said coupling being rigid with one section and capable of turning or rotating upon the other section, a lever rigid with said coupling, and a locking device carried by said lever and adapted to engage said rank, whereby the land-side wheel is capable of movement relatively to the plow.

15. In a wheeled plow, the combination of a suitable plow and plow-beam, a plurality of supporting-wheels whereof one is a furrow-side wheel, a vertically-disposed spindle upon which said furrow-side wheel is mounted, a bearing rigidly connected with the plow-beam and adapted to slide up and down upon said spindle, a swinging lever, a rock-shaft extending through an ear on said bearing, said rock-shaft being provided with two crank-arms, one of said crank-arms being connected with the upper end of said spindle, and a link connecting the other crank-arm with the said lever, whereby the adjustment of said lever causes the said bearing to slide up or down upon said spindle, so as to raise or lower the forward portion of the plow-beam.

16. In a wheeled plow, the combination of a suitable plow and plow-beam, a plurality of supporting-wheels whereof one is a furrow-side wheel, a vertically-disposed spindle upon which said furrow-side wheel is mounted, a bracket secured to said plow-beam, a bearing adjustably secured to said bracket and adapted to slide up and down upon said spindle, a swinging lever, a rock-shaft extending through an ear on said bearing, said rock-shaft being provided with two crank-arms, one of said crank-arms being capable of adjustment along the said rock-shaft, a link or rod for connecting one of said crank-arms with the upper end of said spindle, and a connecting-rod arranged to connect the other crank-arm with the said lever, the latter thereby being capable of raising and lowering the bearing upon the spindle, so as to raise and lower the forward portion of the plow-beam, and the adjustable connection between the bearing and the said bracket permitting the line of travel of the furrow-side wheel to be changed at will.

17. In a wheeled plow, the combination of a suitable plow and plow-beam, a plurality of supporting-wheels whereof one is a furrow-side wheel, a vertically-disposed rotary spindle having its lower end provided with a laterally-extending arm upon which the said furrow-side wheel is mounted, a bracket secured to said plow-beam, a bearing adjustably secured to said bracket and adapted to slide up and down upon said spindle, a swinging lever, a link and a quadrant rock-shaft serving as medium of connection between the upper end of said spindle and the said bearing, and a link arranged to connect the crushed rock-shaft with the said lever, the adjustment of the lever thereby causing the bearing and the bracket and forward portion of the plow-beam to move up and down upon said spindle, and the adjustable connection between the bearing and the said bracket permitting the line of travel of the furrow-side wheel to be changed at will.

18. In a wheeled plow, the combination of a suitable plow and plow-beam, forward supporting-wheels having shifting connections with the plow-beam, a rear caster-wheel having a stem, e, and bearing in which said stem is free to turn, relatively short links connecting the lower portion of said bearing with the plow-beam, relatively long links connecting the upper portion of the bearing with the plow-beam, the difference in length of the upper and lower links causing the stem to incline rearwardly when the plow is lifted from the ground, a suitable tongue, a suitable connection between said tongue and said caster-wheel, whereby the latter is locked in alinement with the plow-beam when the machine is running straight ahead, regardless of whether the plow is up or down, the tongue when swung to one side automatically releasing the caster-wheel, so as to permit the latter to trail loosely.

19. In a wheeled plow, the combination of a suitable plow and plow-beam, forward supporting-wheels, a rear caster-wheel having a vertically-swinging connection with said plow-beam, the said swinging connection being such that the stem of the caster-wheel tilts or inclines rearwardly when the plow is raised from the ground, a suitable tongue, suitable connection between said tongue and said stem of the caster-wheel, the tongue holding the caster-wheel rigid when the machine is running straight ahead, whether the plow is up or down, a swinging lever, and suitable connections between said lever and said wheels, the lever thereby being operative to simultaneously control all of said wheels, so as to bodily raise and lower the plow.

20. In a wheeled plow, the combination of a suitable plow and plow-beam, forward supporting-wheels, a rear caster-wheel provided with a stem, a shifting connection between said stem and said plow-beam, the connection being such that the stem tilts or inclines to the rear when the plow is raised from the ground, a suitable tongue, connections whereby the tongue holds the caster-wheel against lateral side swing while the machine is running straight ahead, the connections permitting the tongue when swung to one side to automatically release the caster-wheel, a swinging lever, and connections whereby the adjustment of the lever causes the plow to rise or fall.

21. In a wheeled plow, the combination of a suitable plow and plow-beam, a crank-axle journaled in a bearing on said plow-beam, a furrow-side wheel having a shifting connection with said plow-beam, a rear caster-wheel having a shifting connection with said plow-beam, a hand-lever rigidly secured to said crank-axle, a land-side wheel mounted upon said crank-axle, a pull-rod for connecting said lever with the rear caster-wheel, suitable connection between said lever and the said furrow-wheel, the said lever thereby being operative to simultaneously control all of said wheels, so as to raise and lower the plow, and a second lever for independently adjusting the land-side wheel.

22. In a wheeled plow, the combination of a suitable plow and plow-beam, a crank-axle journaled in a bearing on said plow-beam, a land-side wheel on said crank-axle, a lever rigidly secured to said crank-axle, a suitable furrow-side wheel, a rear caster-wheel having a shifting connection with the plow-beam, a pull-rod serving as medium of connection between said lever and said caster-wheel, the lever thereby being operative to simultaneously control both the caster and the land-side wheel, and a second lever for independently adjusting or controlling the land-side wheel.

23. In a wheeled plow, the combination of a suitable plow and plow-beam, a rear caster-wheel provided with a vertically-disposed stem, a suitable bearing in which said stem is free to turn, upper and lower links connecting said bearing with the plow-beam, a crank-axle journaled in the bearing on said plow-beam, a land-side wheel mounted on said crank-axle, a lever connected and arranged for adjusting the land-side wheel without turning the portion of the crank-axle which is mounted in said bearing on the plow-beam, a furrow-side wheel having a shifting connection with said plow-beam, and a second hand-lever connected and arranged for simultaneously controlling all of said wheels, so as to raise and lower the plow.

24. In a wheeled plow, the combination of a suitable plow and plow-beam and a plurality of supporting-wheels, a pivoted lever, a bell-crank arranged to raise the rear portion of the plow-beam, and a pull-rod serving as medium of connection between said lever and said bell-crank, the pull exerted by said rod operating to raise the plow.

25. In a wheeled plow, the combination of a suitable plow and plow-beam and a plurality of supporting-wheels, a crank-axle upon which one of said supporting-wheels is mounted, a vertically-disposed spindle upon which one of said supporting-wheels is mounted, a lever which is rigidly secured to said crank-axle, a shifting connection between the plow-beam and said spindle, and a link and a crank-shaft for connecting said lever with said shifting connection, the adjustment of the lever thereby causing the forward portion of the plow-beam to move up or down.

26. In a wheeled plow, the combination of a suitable plow and plow-beam, a crank-axle journaled in a bearing on said plow-beam, a land-side wheel mounted on said crank-axle, a furrow-side wheel having a shifting connection with the plow-beam, a rear caster-wheel having a shifting connection with the plow-beam, a lever rigidly secured to said crank-axle and provided with a downwardly-extending and relatively short arm, a pull-rod arranged to connect said relatively short and downwardly-extending lever-arm with the rear caster-wheel, and a second lever for independently adjusting or controlling the land-side wheel.

27. A frameless high-lift sulky-plow, comprising furrow and land side wheels capable of relative adjustment, a rear caster-wheel capable of relative shift or adjustment, a crank-axle upon which one of said wheels is mounted, a lever rigidly secured to said crank-axle, link connections between said hand-lever and the other wheels, the said lever thereby being operative to simultaneously control all of said wheels, so as to raise and lower the plow.

28. In a wheeled plow, the combination of a suitable plow and plow-beam, forward supporting-wheels, a rear supporting-wheel, a pivoted lever, said lever having a downwardly and rearwardly projecting arm, a connection between said arm and said rear supporting-wheel, suitable connections between said lever and the forward supporting-wheels, the connections and relative arrangement being such that the plow-point is always below the heel when the plow is in the ground.

29. In a wheeled plow, the combination of a suitable plow and plow-beam, supporting-wheels, a pivoted lever provided with a downwardly and rearwardly projecting arm, a link connecting said arm with one of said wheels, suitable connection between the lever and the other supporting-wheels, the connections and relative arrangement being such that the plow-point is always below the heel when the plow is in the ground.

30. In a wheeled plow, the combination of a suitable plow and plow-beam, a rear caster-wheel, a bell-crank serving as a medium of connection between said caster-wheel and said plow-beam, a crank-axle, a land-side wheel mounted on said axle, a lever rigidly secured to said axle, said lever being provided with a downwardly and rearwardly extending arm, a link for connecting said arm with said bell-crank, a furrow-side wheel having a shifting connection with said plow-beam, suitable connections between said lever and said furrow-side wheel, said lever thereby being operative to simultaneously control all of said wheels, so as to raise or lower the plow, and the connections and relative arrangement being such that the plow-point is always below the heel when the plow is in the ground.

31. A plow and beam, a front furrow-wheel, a rear caster-wheel, a land-side wheel, a hand-lever connected and arranged for simultaneously controlling all of said wheels, so as to raise and lower the plow and maintain the plow-point below the heel while the plow is in the ground, and another lever for independently controlling the said land-side wheel.

32. A wheeled plow comprising a suitable plow and plow-beam, forward supporting-wheels, a rear caster-wheel, a pivoted lever connected and operative to simultaneously control all of the wheels, so as to raise

and lower the plow, the connections and relative arrangement being such that a throw of said lever beyond a certain point confines the adjustment or relative movement to the forward wheels.

33. A frameless high-lift sulky-plow, comprising a suitable plow and plow-beam, a rear caster-wheel having a shifting connection with the rear upright portion of the plow-beam, land-side and furrow-side wheels having shifting connections with the horizontally-disposed portion of the plow-beam, a lever connected and arranged for simultaneously operating all of said shifting connections, so as to cause a bodily rise and fall of said plow, and a second lever connected and arranged for operating the shifting connection between the plow-beam and land-side wheel independently of the others.

34. A frameless high-lift sulky-plow, comprising a suitable plow and plow-beam, a rear caster-wheel having a shifting connection with the plow-beam, a forward furrow-wheel having a shifting connection with the plow-beam, a crank-axle mounted in a bearing on said plow-beam, a lever suitably mounted upon said axle and connected for simultaneously rotating the latter and operating both of said shifting connections, a land-side wheel mounted upon said axle, and a second lever connected and arranged for controlling said land-side wheel independently of the other wheels.

35. A wheeled plow comprising a plow and plow-beam, land-side and furrow-side wheels having shifting connections with the plow-beam, a rear caster-wheel having a shifting connection with the plow-beam, a lever connected and arranged for simultaneously controlling all three wheels, so as to raise and lower the plow, a driver's seat mounted on the caster-wheel, and a tongue connected and arranged to control the furrow-side and caster wheels.

36. The combination of a plow and beam, a rear caster-wheel, a land-side wheel, a furrow-side wheel, a tongue connected and arranged to control the caster-wheel and furrow-side wheel, a lever for simultaneously adjusting all three wheels, so as to raise and lower the plow and beam, a driver's seat mounted on the caster-wheel, and a second lever for independently adjusting the land-side wheel.

707,880. CLOTHES-HANGER. ARTHUR W. VAN DEMARK, Lestershire, N. Y. Filed Apr. 16, 1902. Serial No. 103,123. (No model.)

Claim.—1. A hanger of the class described, comprising a support, hook-screws adapted to be screwed therein to, a plate-spring mounted on said screws, and a rod inserted in the heads of the hook-screws and bearing on the said spring, said rod being provided with hooks, substantially as shown and described.

2. A device of the class described comprising a support, keepers secured thereto, a vertically-adjustable member mounted in said keepers, and provided with a plurality of hooks and a spring placed between said support and said vertically-adjustable member, substantially as shown and described.

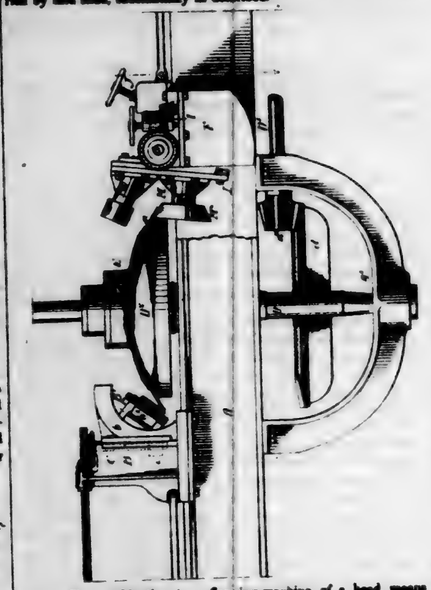
707,881. FLANGING-MACHINE. JOHN H. VANDERSLICE, Centerville, Pa., assignor to Lukens Iron and Steel Company, Centerville, Pa., a Corporation of Pennsylvania. Filed Aug. 2, 1901. Serial No. 70,594. (No model.)

Claim.—1. The combination as a flanging-machine, of a head, means for clamping a plate to be flanged to said head, means for flanging the plate, a slide on said carriage having rollers, said rollers being relatively apart from one another, with means for moving said slide whereby either of the rollers may be brought into contact with the plate operated upon, substantially as described.

2. The combination in a flanging-machine, of a head, means for clamping a plate on said head, means for flanging said plate, a carriage independent of said flanging means, a frame pivoted to said carriage, a slide mounted on said frame, means for adjusting the frame, means for adjusting the slide, and a roller carried by the slide arranged to bear upon the plate to be flanged, substantially as described.

3. The combination in a flanging-machine, of a head, means for clamping a plate on said head, means for flanging said plate, a carriage, a frame pivoted to said carriage, a slide mounted on said frame, means for adjusting the frame, means for adjusting the slide, with two rollers mounted on the slide independently of the flanging means, one arranged to bear upon one side of the plate and the other to bear upon the opposite side of the plate, substantially as described.

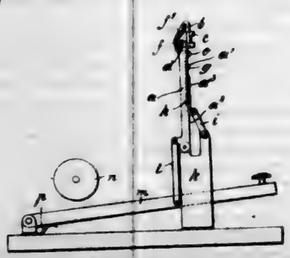
4. The combination in a flanging-machine, of a head, means for clamping a plate on the head, means for flanging said plate, a carriage, a frame pivoted to the carriage, a shaft for adjusting said frame, a slide mounted on the frame, a rack on said slide, an operating-shaft, a gear-wheel on said shaft meshing with the teeth of the rack, and a roller carried by said slide, substantially as described.



5. The combination in a flanging-machine, of a head, means for clamping a plate on the head, means for flanging said plate, a carriage, a frame pivoted to the carriage, a shaft for adjusting said frame, a slide mounted on the frame, a rack on said slide, an operating-shaft, a gear-wheel on said shaft meshing with the teeth of the rack, and a roller carried by said slide, with a wheel on the said shaft, a counterbalance-weight suspended from said wheel to counterbalance the slide and its roller, and means for operating said shaft, substantially as described.

6. The combination in a flanging-machine, of a head, means for clamping a plate to the head, means for flanging said plate, with two rollers independent of said means, bearings therefor, said rollers being so mounted in respect to the plate to be flanged that during the first part of the process of flanging one roller can be adjusted to bear against the under side of the plate, and during the last part of the process of flanging the other roller can be adjusted to bear upon the opposite side of the plate, substantially as described.

707,882. TYPE-WRITING MACHINE. JOHANNES H. VIEK, Deventer, Netherlands. Filed Apr. 10, 1902. Serial No. 102,264. (No model.)



Claim.—1. The combination of the key-lever *m*; standard *k*; type-lever *a*, formed with two parallel sides providing a longitudinal cavity between them and fulcrumed on the standard; connecting-rod *l* imparting movement from the key-lever *m* to the type-lever *a*; type-bar carrier *b* pivoted to the end of the lever *a*; and the guided bar *g* sliding in the cavity of the type-lever *a*, connected at one end by the rod *i* to the standard *k* and at the other end to the type-carrier *b* and imparting oscillatory motion to said type-carrier by the movement of the lever *a*, as explained.

2. The combination of the standard *k*; key-lever *m*; type-lever *a*, and connecting-rod *l* pivoted to the standard *k*; oscillating type-bar carrier *b*, having a curved slot *f* and pivoted on the free end of the lever *a*; type-bar *c* mounted on the carrier *b*; sliding bar *g* connected at one end to rod *i* and guided in the lever *a* by pins *o* and *h* and the slide *f* working in the slot *f* and communicating oscillatory motion to the type-bar carrier by the movement of the lever *a* on standard *k*, substantially as described.

707,883. SOSPIECE FOR EYEGLASSES. CHARLES F. WALL, Philadelphia, Pa. Filed Feb. 7, 1902. Serial No. 93,923. (No model.)

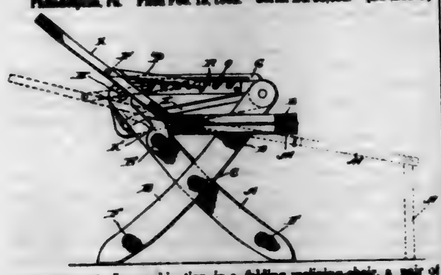
Claim.—1. In an eyeglass, a nosepiece-clamp and a compound spring in addition to and having both portions connected with said nosepiece-clamp, one portion of said spring carrying the clamp and the other having yielding connection therewith, said springs being disposed to act one against or in opposition to the other at opposite ends of said clamp.

2. In an eyeglass, a nosepiece-clamp, a compound spring formed independent of said nosepiece-clamp and composed of independent members of different tension, one attached to said clamp and the other having movable connection therewith, said springs mounted one at each end of said clamp to act one against the other, the one to regulate and to modify the pressure at the lower end and the other to regulate and increase the pressure at the upper end of said clamp.

3. In an eyeglass, a nosepiece-clamp, a compound spring formed of independent members of different tension formed separate from said nosepiece-clamp, one member being connected with the upper end of said clamp and doubled up upon itself and the other member with the lower end thereof, both members having a common connection with the post of the glasses.

4. In an eyeglass, a nosepiece-clamp and a compound spring formed of independent members of different tension, said members each having an end connected with the post of the glasses, by means common to both of said ends, one member being movably connected with the lower end of the clamp and the other member doubled upon itself and having its other end secured to the upper end of said clamp.

707,884. FOLDING RECLINING-CHAIR. PETER B. WATSON, Philadelphia, Pa. Filed Feb. 13, 1902. Serial No. 93,932. (No model.)

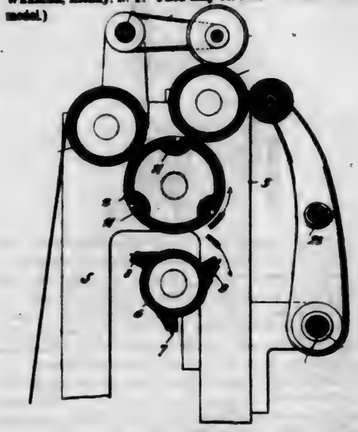


Claim.—1. In combination in a folding reclining-chair, a pair of cross-legs arranged upon each side of the chair, said legs pivoted together upon a common cross-rod, cross-rods D and E connecting the two sets of legs together above the pivotal point, an arm pivoted at one end to the upper end of one leg of each set, said arm provided with a slot, pins or rollers secured to the upper end of each of the other legs of the set, said pins or rollers lying within the slot, a back pivoted to the cross-rod E, a seat hinged to the lower end of the back, braces pivoted to each side of the back, means secured to the arms for locking the forward end of the braces in whatever position placed, as and for the purpose specified.

2. In combination in a folding reclining-chair, a set of cross-legs A and B located upon opposite sides of the chair, a cross-rod extending across the chair upon which the legs are pivoted together, a cross-rod E extending between the two legs above the pivotal point, a cross-rod D extending between and connecting the two legs B above the pivotal point, two arms, each pivoted to the upper end of one of the legs A, said arms provided with a slot I, rollers or pins secured in the upper end of the legs A, said rollers or pins lying within the slots I, a back pivoted to the rod E, a seat hinged to the lower end of the back, said seat adapted to be supported by the cross-rod D, a leg-rest pivoted to the forward end of the seat, folding supports for said leg-rest, a rack provided upon the arms, braces pivoted to each side of the back, the forward end of said braces adapted to engage the teeth of said rack and hold the back in certain positions, as and for the purpose specified.

3. In a chair of the character described, two sets of cross-legs arranged upon each side of the chair, each set composed of the legs A and B, a cross-rod C extending across the chair upon which each set of legs is pivoted, a cross-rod E connecting the legs A of each set together above the pivotal point, a second cross-rod D connecting the legs B of each set together above the pivotal point, cross-rods F extending between the legs of each set below the pivotal point, two arms pivoted to the outside of the upper end of each of the legs A, rollers or pins secured in the upper end of each of the legs B, slots I provided in the arms in which the rollers or pins work, said slots being so arranged and so formed that the arms will be caused to assume a position in a straight line with the legs when the legs are folded together, a back pivoted to the cross-rod E, a seat hinged to the lower end of the back and adapted to fold upward against the same, said seat supported by the cross-rod D, a leg-rest hinged to the forward edge of the seat, recesses O formed in each side of the leg-rest, legs N pivoted in the forward end of said recesses and adapted to be folded entirely within the recesses when not in use, the arms provided with recesses, racks arranged within the recesses, the teeth of said rack being inclined forward, braces or supplementary arms P pivoted to the back upon each side, a catch provided upon the forward end of the braces or supplementary arms and adapted to engage the teeth, a space being provided between the upper edge of the teeth and the upper wall of the recess to allow the catches to pass to and fro above the teeth, substantially as and for the purpose specified.

707,885. MACHINE FOR PERFORATING PAPER. SETH WHEELER, Albany, N. Y. Filed May 10, 1901. Serial No. 59,562. (No model.)



Claim.—1. In a machine for perforating paper, the combination with suitable perforating mechanism, of a swinging frame adapted to support a rewinding-shaft, a rewinding-shaft supported thereby, a revolvable bushing with which the said shaft has a removable connection, and a sliding bearing-bushing arranged to engage the opposite end of the said shaft.

2. In a machine for perforating paper, the combination with suitable perforating mechanism, of a rewinding-shaft, a revolvable bushing with which said shaft has a removable connection, means for locking the shaft in its engagement with the revolvable bushing, and a sliding bearing arranged to normally support the opposite end of the said shaft and to be slid out of engagement therewith when desired.

3. In a machine for perforating paper, the combination with suitable perforating mechanism, of a rewinding-shaft, a revolvable bushing with which one end of the said shaft has a removable connection, a sliding pin concentrically arranged within the said bushing and adapted to extend into the said shaft, a sliding bearing arranged to normally support the opposite end of the said shaft, and means whereby the said bearing may be moved out of engagement with the said shaft when desired.

4. In a machine for perforating paper, the combination of a rotary die and a rotary cutter connected together by gear-wheels, one of said gear-wheels comprising a hub and a gear-ring adjustably mounted thereon.

5. The combination in a machine for perforating paper of a rotary

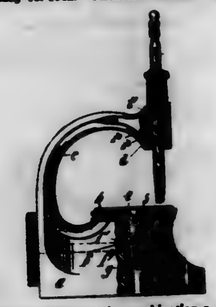
die and a rotary cutter connected together by gear-wheels, one of the said gear-wheels having two gear-rings rotatably adjustable with relation to each other.

6. The combination in a machine for perforating paper of a rotary die and a rotary cutter connected together by gear-wheels, one of said gear-wheels comprising a hub and two gear-rings mounted thereon, said gear-rings being rotatably adjustable relatively with each other and with the hub, together with means for locking the gear-rings and the hub together in the position to which they have been adjusted.

707,886. PROCESS OF MANUFACTURING MANURE FROM APATITE OR SIMILAR MINERAL PHOSPHATE. JOHAN G. WESTMAN and WILHELM PALMAER, Stockholm, Sweden. Filed Oct. 22, 1900. Serial No. 33,995. (No specimens.)

Claim.—The process herein described of manufacturing manure from apatite or similar mineral phosphate, said process consisting in passing an electric current through an electrolytic bath having an anode and cathode and containing an electrolyte consisting of a solution of a salt disengaging at the anode an acid which forms a soluble salt with lime, while at the cathode a basic hydrate is formed, dissolving the mineral phosphate by the acid disengaged and precipitating the same in the alkaline liquid of the cathode as phosphate of calcium, but in another more soluble form, all substantially as set forth.

707,887. WATCHMAKER'S STAKING-TOOL. LEWIS J. WILLIAMS, Lebanon, N. H., assignor to Frank B. Kendrick and William F. Davis, Lebanon, N. H., partners trading as The Firm of Kendrick & Davis. Filed May 10, 1902. Serial No. 106,762. (No model.)



Claim.—1. In a staking-tool, in combination a perforated base, a punch or plunger, a guide therefor, and means adapted to frictionally engage said punch or plunger whereby said punch or plunger may be sustained in said guide in any desired position relative to said base.

2. In a staking-tool, in combination a perforated base, a punch or plunger, a guide therefor, and means comprising a plurality of spring-tongues adapted to engage said punch or plunger whereby it may be sustained in said guide in any desired position relative to said base.

3. In a staking-tool, in combination a perforated base, a punch or plunger, a guide therefor, a means comprising a sleeve countersunk in said guide and a plurality of spring-tongues carried thereby and adapted to engage said punch or plunger whereby it may be sustained in said guide in any desired position relative to said base.

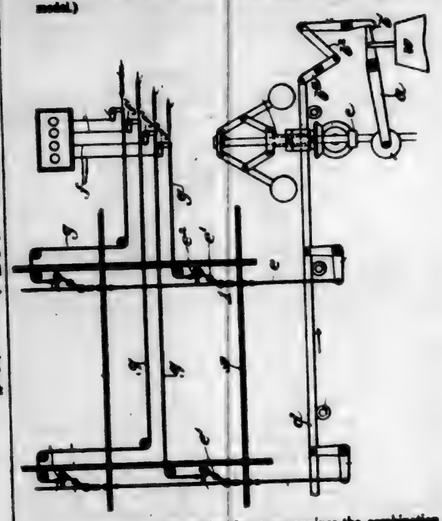
4. In a staking-tool, in combination a perforated base, a punch or plunger, a guide therefor, and means comprising a sleeve countersunk in said guide a plurality of spring-tongues carried thereby and bearing-surfaces carried by said tongues and adapted to engage said punch or plunger whereby it may be sustained in any desired position relative to said base.

5. In a staking-tool, in combination, a perforated base, a punch or plunger, a retentive face-plate carried by said base, a pivot-pin connecting said base and said plate, a cam whereby said pivot-pin is reciprocated to release or clamp said face-plate and means comprising an adjustable contact carried by said pivot-pin and acting against said cam whereby the throw of said pivot-pin by said cam may be regulated.

6. In a staking-tool, in combination, a perforated base, a punch or plunger, a retentive face-plate carried by said base, a pivot-pin connecting said base and said plate, a cam whereby said pivot-pin is reciprocated to release or clamp said face-plate and a set-screw carried by said pivot-pin.

7. In a staking-tool, in combination a perforated base, a punch or plunger, a retentive face-plate carried by said base, a pivot-pin connecting said base and said face-plate having an opening extending therethrough, a shaft seated in said base and extending through said opening a portion of said shaft being reduced and eccentric, said portion being within the opening in said pivot-pin, whereby shoulders are formed to bear upon the reverse sides of said pivot-pin, and said face-plate may be released from or clamped against said base.

707,888. STOP-MOTION FOR STEAM-ENGINES. OWEN WILLIAMS, Fall River, Mass. Filed Nov. 30, 1899. Serial No. 38,162. (No model.)



Claim.—1. In a stop-motion for steam-engines the combination of the steam-controlling device, the weighted lever arranged to engage and actuate the steam-controlling device to cut off the steam, a detent arranged to hold the weighted lever normally against movement, and connecting mechanism connecting said detent with various locations whereby the detent may be operated from different locations to release the weighted lever in order that it may act on the steam-controlling device, substantially as described.

2. In a stop-motion for steam-engines the combination of the steam-controlling device, means for actuating the same to cut off the steam, the main slide-rod having connection with the means for actuating the steam-controlling device, the bell-crank lever, the vertical connections for operating said bell-crank lever, the pulls or hooks arranged to form a supporting and lifting means for moving the vertical connecting-rods to actuate the slide-rod, substantially as described.

3. In a stop-motion for steam-engines the combination of the steam-controlling device, means for actuating it to cut off the steam, the slide-rod having connection with said actuating means, connecting-rods by which the slide-rod may be moved from different locations, the indicator and its actuating means arranged to be operated by devices connected with the vertical connecting-rods, substantially as described.

4. In a stop-motion for a steam-engine, the combination with a governor or steam-regulating device of a weighted lever arranged to engage and actuate said governor to cut off the steam, a detent arranged to engage said weighted lever, a longitudinal slide-rod having connection with said detent in order to release it from engagement with said weighted lever, means having engagement with said slide-rod at various points thereon for actuating the slide-rod, an indicator device so connected that the slide-rod-actuating means has to be operated by the operation of the actuating means at any point, substantially as described.

707,889. PROCESS OF EXTRACTING SUGAR FROM ITS SOLUTIONS. ALFRED WEIL, Christiansberg, Germany. Filed Dec. 21, 1900. Serial No. 372,294. (No specimens.)

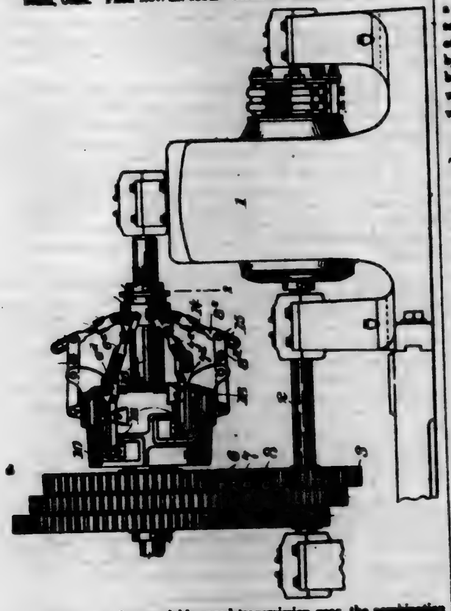
Claim.—1. The process for extracting sugar from molasses and other impure after-products obtained in the manufacture of sugar, which consists in mixing molasses with a watery solution of an alkali acid, stirring the mixture together with finely-ground protecid of lead, allowing the mixture to stand until a viscous mass has formed, and washing with water, substantially as and for the purpose stated.

2. In the process for extracting sugar by the agency of lead protecid from molasses and other impure after-products obtained in the manufacture of sugar, the method of freeing the lead sucrate from the adhering impurities by diluting the mixture with water of a temperature of 40° to 50° centigrade, filter-pressing and washing the contents of the filter-press first with water of 40° to 50° centigrade and then with water the temperature of which is gradually raised to 70° to 75° centigrade, substantially as and for the purpose stated.

3. In the process for extracting sugar by the agency of lead protecid from molasses and other impure after-products obtained in the manufacture of sugar, the method of removing the last traces of lead from the sugar liquor obtained by the carbonating process, which consists in concentrating the sugar liquor, adding one-fourth to one-half per cent. of calcium hydrate, treating with carbonic acid at a temperature of 80° to 90° centigrade, and separating the liquor from the precipitate, substantially as described.

4. The process for extracting sugar from molasses and other impure after-products obtained in the manufacture of sugar, which consists in mixing the molasses, &c., in the proportion of not more than three parts of water for every one part of molasses, &c., with an excess of lead protecid as free as possible from the red modification of lead protecid, adding a hydrated alkali; allowing the mixture to stand at ordinary temperature until a homogeneous viscous mass has formed containing the sugar in the form of lead sucrate, thinning the mass with water having a temperature of 40° to 50° centigrade, filter-pressing the mass, washing the contents of the filter-press with water having an initial temperature of 40° to 50° centigrade which is then gradually raised up to 70° to 75° centigrade, decomposing the washed lead sucrate, separating the precipitate from the sugar liquor, concentrating the liquor, adding one-fourth to one-half per cent. of calcium hydrate, carbonating at a temperature of from 80° to 90° centigrade, and filtering, substantially as described.

707,890. VARIABLE-SPEED CLUTCH. WILLIAM A. WOOD, Ansonia, Conn. Filed Nov. 22, 1901. Serial No. 83,260. (No model.)



Claim.—1. In a variable-speed-transmission gear, the combination of a driving-shaft, a driven shaft, a plurality of sleeves loosely mounted on the driven shaft, gearing connecting said sleeves to the driving-shaft and so proportioned as to rotate said sleeves at different rates of speed, separate clutching means for locking each of said sleeves to the driven shaft, and interconnecting means whereby when any one of said means is locked to its corresponding sleeve the remaining sleeves are free, said locking means consisting of a pulley with a V-shaped rim carried by the sleeve and a V-shaped clutch-block supported from the driven shaft.

2. In a variable-speed-transmission gear, the combination of a rotating shaft, a plurality of sleeves seated one within another and loosely mounted on said shaft, a plurality of clutch-pulleys mounted one on each of said sleeves, a head fastened to the shaft, surrounding said clutch-pulleys and provided with radial openings opposite the said pulleys, clutch-blocks carried in said openings in said head, and means for forcing the clutch-blocks opposite any one pulley into and out of engagement therewith.

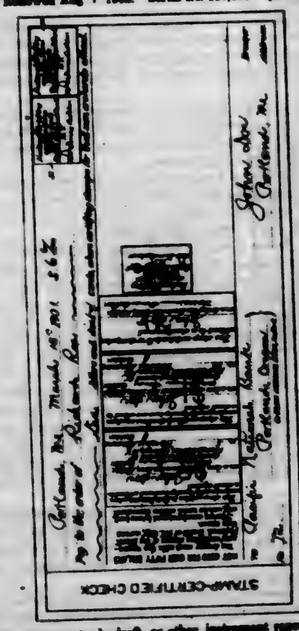
3. In a variable-speed-transmission gear, the combination of a rotating shaft, a plurality of sleeves seated one within another and loosely mounted on said shaft, a plurality of clutch-pulleys mounted one on each of said sleeves, a head fastened to the shaft, surrounding said clutch-pulleys and provided with radial openings opposite the said pulleys, clutch-blocks carried in said openings in said head, and means for forcing the clutch-blocks opposite any one pulley into and out of engagement therewith, together with a single lever and connections therefrom to all of said clutch-blocks, so that only those blocks opposite any one pulley can be thrown into engagement at any one time.

4. In a multiple-clutch mechanism, the combination of a rotating shaft, a series of clutch-blocks mounted on and rotating with said shaft, a series of levers carrying said blocks and mounted on pivots carried by said shaft, a ring adapted to slide longitudinally of said shaft, and a series of links connecting said ring with each of said levers, whereby the sliding of said ring longitudinally of the shaft will cause the clutch-blocks to consecutively approach toward or recede from the shaft, together with suitable clutch members adapted to coöperate with said clutch-blocks whenever the same approach the shaft.

5. In a multiple clutch device the combination of a rotating shaft, a plurality of sleeves loosely mounted on said shaft, a clutch member carried by each sleeve, a series of movable clutch-blocks rotating with the shaft and adapted to grasp or release the respective clutch members, a ring adapted to slide longitudinally of the shaft and toggle-joint connections from said ring to said movable blocks, whereby said blocks are consecutively forced into and released from engagement with their respective coöperating clutch members, as the ring is slid along the shaft.

6. In a multiple-clutch mechanism, the combination of a rotating shaft, a series of clutch-blocks mounted on and rotating with said shaft, a series of levers carrying said blocks and mounted on pivots carried by said shaft, a ring adapted to slide longitudinally of said shaft, and a series of adjustable links connecting said ring with each of said levers, whereby the sliding of said ring longitudinally of the shaft will cause the clutch-blocks to consecutively approach toward or recede from the shaft, together with suitable clutch members adapted to coöperate with said clutch-blocks whenever the same approach the shaft.

707,891. MEANS FOR CERTIFYING CHECKS OR OTHER INSTRUMENTS. JOHN S. ALEXANDER, New York, N. Y. Filed Mar. 20, 1901. Renewed Aug. 1, 1902. Serial No. 117,902. (No model.)



Claim.—1. A check, draft, or other instrument representing value or property, said instrument having affixed thereto a stamp or stamps is-

used by another than the drawer or the instrument, and bearing matter certifying to or guaranteeing the amount for which it is drawn, and also containing an identifying-mark applicable only to the drawer or purchaser of the stamp or stamps and identifying and differentiating said stamp or stamps from other stamps of the same value issued by the same certifier to other purchasers.

2. A certifying-stamp for a check, draft or other instrument representing value or property, said stamp bearing matter certifying to or guaranteeing the face value of said stamp and said stamp having an identifying-mark, other than that of the certifier, applicable only to the purchaser and identifying and differentiating it from other stamps of the same value issued by the same certifier to other purchasers.

3. A certifying-stamp for a check, draft or other instrument representing value or property, said stamp bearing matter certifying to or guaranteeing the face value of said stamp and said stamp having an identifying-signature, other than that of the certifier, applicable only to the purchaser and identifying and differentiating it from other stamps of the same value issued by the same certifier to other purchasers.

4. A check, draft, or other instrument, representing value or property, said instrument having affixed thereto stamps issued by another than the drawer of the instrument, and certifying to or guaranteeing the amount for which it is drawn, each of said stamps having marked upon it in figures, the amount represented by it, the figures upon the stamps representing units of value occupying a different lateral relation thereto from those upon the stamps which represent fractional parts of said unit and figures of the same denomination being in vertical alignment.

707,892. ART OF TREATING STARCH MATERIAL. ALEXANDER P. ANDERSEN, New York, N. Y. Filed Feb. 12, 1902. Serial No. 93,797. (No specimens.)

Claim.—1. The process of treating starch material, which consists in heating such material in a substantially air-dry condition under pressure and then reducing the pressure with such rapidity that the liquid contained in the starch-granules is suddenly gasified.

2. The process of treating starch material, which consists in heating such material in a substantially air-dry condition, under pressure to a point below the boiling-point of the liquid contained in the granules of the starch material at the pressure applied and thereupon suddenly removing said pressure.

3. The process of treating starch material, which consists in heating such material in a substantially air-dried condition and under gas-pressure to a temperature above the boiling-point of the liquid contained in the starch material at normal pressure, and thereupon suddenly reducing the pressure.

4. The process of treating starch material, which consists in heating said material in a substantially air-dry condition and under pressure to a temperature above the boiling-point of water at normal pressure and thereupon suddenly reducing the pressure.

5. The process of treating starch material, which consists in subjecting the material in a substantially air-dry condition to a continuously-increasing pressure while raising its temperature above the boiling-point of water, and then suddenly reducing said pressure.

6. The process of treating starch material, which consists in raising the material in a substantially air-dry condition to a temperature of substantially 120° centigrade, while simultaneously subjecting it to a fluid-pressure above the normal, and then suddenly reducing said pressure.

7. The process of treating starch material, which consists in raising the material in a substantially air-dry condition to a temperature not exceeding 200° centigrade, while simultaneously subjecting it to fluid-pressure above the normal, and then suddenly reducing said pressure.

8. The process of treating starch material, which consists in raising the material in a substantially air-dry condition above the boiling-point of water in a closed vessel and then suddenly opening said vessel.

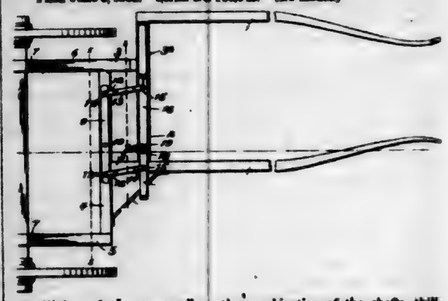
9. The process of treating starch material, which consists in raising the material in a substantially air-dry condition to a temperature not exceeding 200° centigrade, in a closed vessel, and then suddenly opening said vessel.

10. The process of treating starch and material containing starch, which consists in raising the material in a substantially air-dry condition to a temperature not exceeding 200° centigrade, in a closed vessel whose capacity is in excess of the space occupied by the material, and then suddenly opening said vessel.

11. The process of treating cereal grains, which consists in heating the same in a substantially air-dry condition and under pressure to a point above the boiling-point of water at normal pressure and thereafter suddenly reducing the pressure.

12. The process of treating cereal grains, which consists in heating the same in a substantially air-dry condition and under pressure to a temperature not exceeding 300° centigrade, and thereupon suddenly reducing the pressure to a point at which the liquid in the starch granules of the cereal grains will gasify.

707,893. DRAFT-EQUALIZER. ANDREW ANDERSON, Hoda, Minn. Filed June 6, 1902. Serial No. 110,846. (No model.)



Claim.—1. In an equalizer, the combination of the shafts, thill-pieces set to one side of the shafts and connected together, an evener-bar supported between the thill-pieces, a singletree supported between the shafts, and strap connections between the singletree and evener-bar, substantially as described.

2. In an equalizer, the combination of the shafts, thill-pieces set to one side of the shafts, a cross-bar connecting the thill-pieces, an evener-bar pivoted on the cross-bar, a singletree supported between the shafts, and strap connections between the singletree and evener-bar, substantially as described.

3. In an equalizer, the combination of the shafts, thill-pieces set to one side of the shafts, a cross-bar connecting the thill-pieces, an evener-bar pivoted on the cross-bar, a second cross-bar connecting the shafts, a singletree pivoted on the second cross-bar, and strap connections between the singletree and evener-bar, substantially as described.

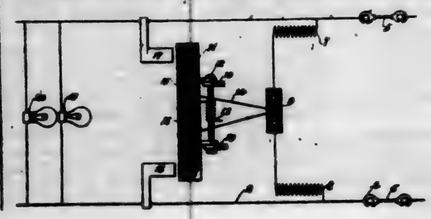
4. In an equalizer, the combination of the shafts, thill-pieces set to one side of the shafts, a cross-bar connecting the thill-pieces, an evener-bar pivoted eccentrically on the cross-bar, a second cross-bar connecting the shafts, a jointed singletree pivoted on the second cross-bar, and strap connections between the singletree and the evener-bar, substantially as described.

5. In an equalizer, the combination of the shafts, thill-pieces set to one side of the shafts, a cross-bar connecting the thill-pieces, an evener-bar pivoted eccentrically on the cross-bar, a second cross-bar connecting the shafts, a singletree comprising two levers jointed together and pivoted on the second cross-bar, and straps connecting the evener-bar with the levers of the singletree, substantially as described.

6. In an equalizer, the combination of the shafts, thill-pieces set to one side of the shafts and connected to the front axle of the vehicle, a cross-bar connecting the thill-pieces, an evener-bar pivoted on the cross-bar to one side of the central line of the vehicle, a second cross-bar connecting the shafts, a jointed singletree pivoted on the second cross-bar coincident with the central line of the vehicle, and straps connecting the evener-bar and the singletree, substantially as described.

7. The combination with the shafts of a vehicle, thill-pieces set to one side of the shafts, a cross-bar connecting the thill-pieces and fastened to one of the shafts, and a second cross-bar connecting the shafts and fastened to one of the thill-pieces, the end of one cross-bar projecting beyond the end of the other cross-bar, substantially as described.

707,894. AUTOMATIC CUT-OUT. GEORGE R. ANDREWS, Providence, R. I. Filed Nov. 1, 1901. Serial No. 80,797. (No model.)



Claim.—1. An automatic cut-out, comprising mains carrying currents of different potential and provided with separate fuses, a fuse connected with both of said mains by means of shunt-wires leading thereto, contact-lugs connected with said mains respectively, and a fuse-controlled member for automatically connecting said lugs together.

2. An automatic cut-out, comprising a plurality of contact-lugs to be connected with respective mains carrying currents of opposite sign, a contact-plate normally out of engagement with said lugs, a spring for forcing said plate into engagement with said lugs, a fuse adjacent to said plate, and a flexible member connecting said fuse and said plate.

3. An automatic cut-out, comprising a plurality of contact-lugs connected with conductors, a plate pivotally mounted adjacent to said lugs a member located adjacent to said plate and provided with a fusible wire, and a flexible member connected with said fusible wire and with said plate.

4. An automatic cut-out, comprising a pair of contact-lugs connected with conductors, a swinging plate for short-circuiting said contact-lugs, a spiral spring for actuating said plate into engagement with said lugs, a member provided with a fusible wire adjacent to said plate, and a longitudinal member secured by its ends to different parts of said plates and engaging said fusible wire.

5. An automatic cut-out, comprising mains provided with fuses connected serially therewith and also connected with contact-lugs, a fuse connected with both of said mains by shunt-conductors, and a fuse-controlled conducting mem- ber connected with the last-mentioned fuse.

6. An automatic cut-out, comprising mains provided with fuses connected serially therewith and also connected with contact-lugs, a fuse connected with both of said mains by shunt-conductors, artificial resistances interposed in the shunt-circuit thus formed for the purpose of modifying the potential of the current passing from said mains to said last-mentioned fuse, and a fuse-controlled conducting member connected with said fuse.

707,895. WRENCH. CLARENCE J. BAKER, Liverpool, N. Y. Filed Jan. 22, 1902. Serial No. 90,261. (No model.)

Claim.—1. A wrench, comprising a handle-bar, a jaw pivoted thereto, and a slidable jaw operatively related to said handle-bar and to the pivoted jaw, said jaws having their opposing active surfaces disposed in converging relation, and the two jaws adapted to be drawn toward each other by the operation of the handle-bar.

2. A wrench, comprising a handle-bar, a swinging jaw pivoted thereto, and a second jaw fitted slidably to a part of the first jaw and having operative connection with the handle-bar, the two jaws having a closing movement relative one to the other on the operation of the handle-bar to turn the work.

3. A wrench, comprising a handle-bar, a swinging jaw provided with a shank which is pivoted to said handle-bar, and a second jaw slidably fitted on the shank of the first-named jaw, and having lever connection with said handle-bar for adjustation thereby.

4. A wrench, comprising a handle-bar, a hinged jaw provided with a shank which is pivoted to said handle-bar, and a movable jaw slidably fitted to the shank of the hinged jaw and having pivotal connection with said handle-bar, said jaws having converging active faces.

5. A wrench comprising a handle-bar, a hinged jaw provided with a straight shank which has pivotal attachment to the handle-bar, and a movable jaw slidably fitted to the shank of the hinged jaw, and having a pivotal connection with the handle-bar at a point to one side of the hinged connection of the first jaw with said handle-bar said jaws having converging active faces.

6. A wrench comprising a handle-bar, a hinged jaw, and another jaw disposed in opposing relation to the hinged jaw and fitted removably and slidably thereto said jaws having converging active faces.

7. A wrench comprising a handle-bar, a hinged jaw, a movable jaw connected with said handle-bar and disposed in cooperative relation to the first-named jaw, and a spring acting against one of said jaws to normally close them together.

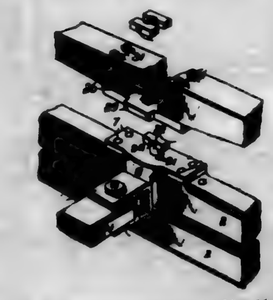
8. A wrench comprising a handle-bar, a jaw provided with a shank which is pivoted to the handle-bar, said jaw having a curved active face which lies eccentrically to the pivot, a movable jaw connected with said handle-bar and having an active face in opposing relation to said eccentric active face of the hinged jaw, and a spring acting against one of said jaws.

9. A wrench comprising a handle-bar, a hinged jaw having an active face, and a movable jaw connected with said handle-bar and having a convex face disposed in continuous opposing relation to the active face of the hinged jaw, said convex face of the movable jaw being provided with a plurality of seats of different sizes.

10. A wrench comprising a handle-bar having rounded heads, a hinged jaw, and a movable jaw provided with recesses arranged to receive said rounded heads of the handle-bar.

11. A wrench comprising a handle-bar, a hinged jaw having its shank formed with an offstanding lug which is pivoted to the handle-bar, and a slidable jaw provided with flanged guide-plates having slidable and detachable engagement with the shank of the hinged jaw.

707,896. RUNNING-GEAR FOR WAGONS. JAMES E. BENNETT, Hennessey, Ill. Filed Nov. 13, 1901. Serial No. 82,462. (No model.)



Claim.—1. A reach-coupler constructed with a king-bolt or wear-plate, a drop-piece, and lower and upper plates extending from the drop-piece and having pin-holes for the reception of a coupling-pin whereby the end of a reach is fastened to the upper and lower plates.

2. A reach-coupler constructed with a wear-plate adapted to be fastened to the top of the sand-bar, a drop-piece adapted to fit against a side of the sand-bar, and lower and upper plates extending from the drop-piece, and having pin-holes for the reception of a coupling-pin whereby the end of a reach is fastened to the plates.

3. A reach-coupler constructed with a wear-plate adapted to be fastened to the top of a sand-bar, a drop-piece adapted to fit against a side of the sand-bar, lower and upper plates extending from the drop-piece, and having pin-holes for the reception of a coupling-pin whereby the end of a reach is fastened to the plates, a king-bolt secured to the wear-plate having radial lugs providing a T-shaped head and a removable divided locking-piece fastened to the king-bolt.

5. The combination of an axle, a sand-bar, coröperating and fastened to the axle, a reach-coupler constructed with a wear-plate fastened to the top of the sand-bar, a drop-piece fitting against a side of the sand-bar, and lower and upper plates having pin-holes and extending from the drop-piece, and a coupling-pin extending through the pin-holes for removably fastening the end of a reach to the lower and upper plates.

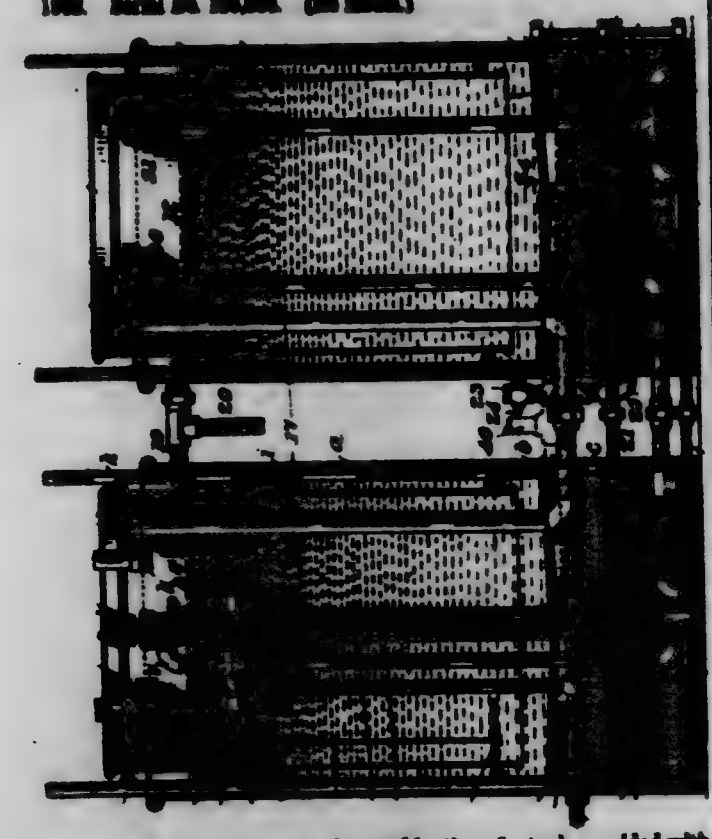
6. The combination of an axle, a sand-bar, coröperating and fastened to the axle, a reach-coupler constructed with an inner part formed with a wear-plate fastened to the top of the sand-bar, and a drop-piece fitting against a side of the sand-bar, and an outer part fastened to the drop-piece and sand-bar, and formed with lower and upper plates having pin-holes and extending from the drop-piece, and a coupling-pin extending through the pin-holes for removably fastening the end of a reach to the lower and upper plates.

7. The combination of an axle, a sand-bar coröperating and fastened to the axle, a reach-coupler constructed with a lower wear-plate fastened to the sand-bar, a king-bolt, a bolster having a central recess at the under side, an upper wear-plate having a central opening and fastened to the bolster across the recess, and a locking-piece detachably secured to the king-bolt within the recess.

8. The combination of an axle, a sand-bar coröperating and fastened to the axle, a reach-coupler constructed with a lower wear-plate fastened to the sand-bar, a king-bolt having a head formed with radial lugs in line

with the wear-plate, and an axial bolt-hole, a holster having a central recess at the under side, an upper wear-plate having a central opening transverse thereof corresponding in shape to the head of the king-bolt, a divided locking-piece within the recess and a bolt extending through the locking-piece and through the bolt-hole of the head for detachably securing the locking-piece to the head.

707,897. CARBURETER. WILLIAM F. REESE, Portsmouth, Va., assignor of one-half to Robert T. Thorp, Norfolk, Va. Filed May 8, 1902. Serial No. 105,608. (No model.)



Claim.—1. In a carbureter, the combination of a tank provided with separate chambers, a perforated pipe spirally coiled in each of said chambers, a pipe connected to both ends of the spiral coil in one of said chambers, means for forcing air through said pipe, and connections running from the first chamber to both ends of the spiral pipe in the second chamber.

2. In a carbureter, the combination of a tank provided with a carbureting-chamber, a bell in said tank, a perforated spiral coil in said chamber, an air-pipe connected by branch pipes to both ends of said spiral pipe, said air-pipe extending up inside of said bell, and means for forcing air into said bell.

3. In a carbureter, the combination of a plurality of similarly-shaped tanks and pipes connecting the same, one of said pipes running to the top of said tanks and provided with a check-valve, carbureting-chambers in said tanks, bells in said tanks, spirally-arranged perforated pipes in said chambers and air-pipes connected by branch pipes to each end of each of said spiral pipes, said air-pipes running nearly to the top of one of said tanks, and means for forcing air from one of said tanks into the other.

4. In a carbureter, the combination of a plurality of similar tanks each provided with a plurality of carbureting-chambers, bells in said tanks, liquid and air pipes connecting said chambers and tanks, spirally-arranged perforated pipes in the lower one of said chambers in each of said tanks, air-pipes connected to both ends of each of said spirally-arranged pipes, spirally-arranged perforated pipes in the upper carbureting-chambers in each of said tanks, connections leading from said lower chambers to both ends of the spiral pipes arranged in the upper of said above-mentioned chambers, means for introducing gasolene and water into said tanks, and means for causing air to enter said bells.

707,898. ARTIFICIAL STONE. FRANCIS BAAS, St. Eustatius, Canada. Filed Aug. 26, 1901. Serial No. 73,201. (No specimens.)

Claim.—1. The process for manufacturing artificial stone which consists in mixing silicate of magnesia of any degree of subdivision with a small amount of lime and a sufficient quantity of water to impart plasticity to the mixture, then dividing the plastic mixture into parts of any desired shape and size, and submitting the same directly to the action of steam.

2. The process of manufacturing artificial stone, which consists in crushing any kind of magnesia rock into any degree of subdivision, mixing the same with sand and a small amount of lime, making moldings therefrom and treating the moldings with steam.

3. In the process of manufacturing artificial stone, treating material containing magnesia in excess by weight of lime with steam, substantially as described.

4. In the process of producing artificial stone, slaking lime and treating the same with steam in presence of an excess of magnesia by weight, as compared with the amount of lime, and in presence of sand, substantially as described.

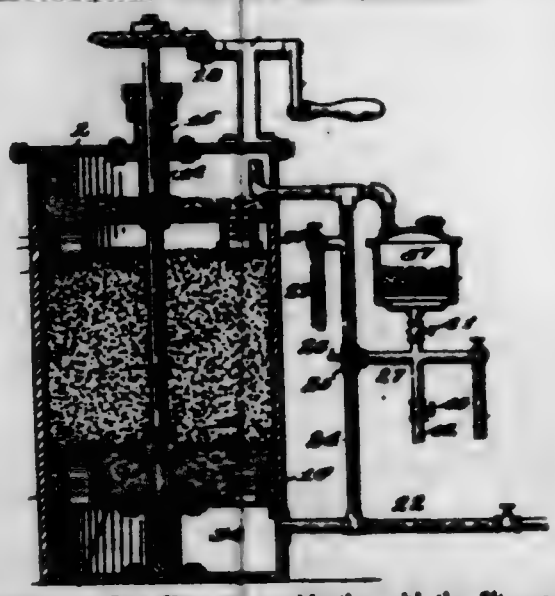
5. The process for manufacturing artificial stone, which consists in mixing an excess by weight of sand with a small amount of lime, adding magnesia in any form or condition thereto, the magnesia being in excess of lime by weight, and treating the mixture with steam, substantially as described.

6. In the process of manufacturing artificial stone, slaking lime, mixing the same with material containing magnesia as a chief component and in any state or degree of subdivision, adding sand and molding the mixture, substantially as described.

7. As a new article of manufacture, an artificial stone, containing silicate of magnesia and lime, the magnesia being in excess of lime by weight, substantially as described.

8. A composition of matter, comprising sand, largely in excess by weight, silicate of magnesia and silicate of lime, the magnesia being in excess of lime by weight, substantially as described.

707,899. FILTER. FERDINAND BUSHARENS, New Orleans, La. Filed Dec. 31, 1901. Serial No. 87,268. (No model.)



Claim.—1. In a filter, the combination with the filter-casing having an inlet in its upper end and an outlet in its lower end, of a perforated diaphragm fitted in the upper part of the casing below the inlet, slitted tubes fitted at their upper ends in said perforations and closed at their lower ends, a collecting-chamber arranged in the lower end of the casing and connecting with the outlet, slitted tubes projecting upwardly from said collecting-chamber and closed at their upper ends, and filtering-beds arranged respectively above and below the diaphragm in the upper portion of the filter-casing, substantially as described.

2. In a filter, the combination with the filter-casing having an inlet in its upper end and an outlet in its lower end, of a perforated diaphragm fitted in the upper part of the casing below the inlet, slitted tubes fitted at their upper ends in said perforations and closed at their lower ends, a collecting-chamber arranged in the lower end of the casing and connecting with the outlet, slitted tubes projecting upwardly through said collecting-chamber and closed at their upper ends, and means for reversing the passage of the water through the filter, substantially as described.

3. In a filter, the combination with the filter-casing having an inlet in its upper end and an outlet in its lower end, of a perforated diaphragm fitted in the upper part of the casing below the inlet, slitted tubes fitted at their upper ends in said perforations and closed at their lower ends, a collecting-chamber arranged in the lower part of the casing and communicating with the outlet, slitted tubes projecting upwardly from said collecting-chamber and closed at their upper ends, a filter-bed of iron filings arranged in the casing above the upper diaphragm, and a filter-bed of sand arranged in the casing below the upper diaphragm, substantially as described.

4. In a filter, the combination with the filter-casing having an inlet in its upper end, and an outlet in its lower end, of a perforated diaphragm fitted in the upper part of the casing below the inlet, slitted tubes fitted at their upper ends in said perforations and closed at their lower ends, a collecting-chamber arranged in the lower end of the casing and communicating with the outlet, slitted tubes projecting upwardly from said collecting-chamber and closed at their upper ends, filter-beds arranged above

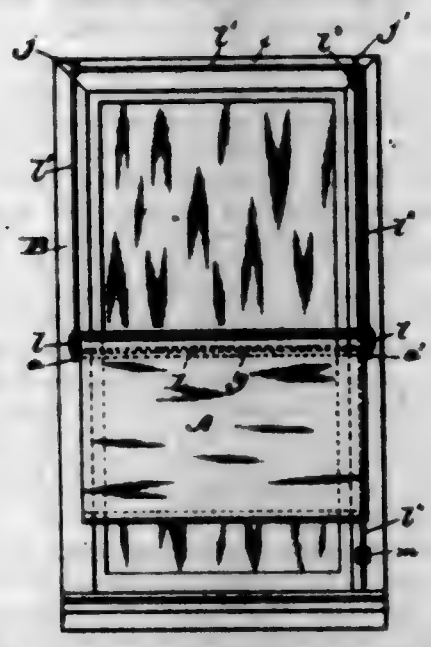
and below the diaphragm in the upper portion of the filter casing, a vertical shaft arranged centrally in the filter-casing and projecting through the top of the latter, perforated stirrer-arms fixed on the lower portion of said shaft above the collecting-chamber, and gearing arranged externally of the casing for rotating said shaft and stirrer-arms, substantially as described.

5. In a filter, the combination with the filter-casing having an inlet in its upper end and an outlet in its lower end, of a perforated diaphragm fitted in the upper part of the casing below the inlet, slitted tubes fitted at their upper ends in said perforations and closed at their lower ends, a collecting-chamber arranged in the lower end of the casing and communicating with the outlet, slitted tubes projecting upwardly from said collecting-chamber and closed at their upper ends, a valved discharge-pipe leading from the outlet, a feed-pipe leading from the discharge-pipe to the inlet, a service-pipe connected with said feed-pipe intermediate the ends of the latter and a three-way valve for diverting the water from the service-pipe to either branch of the feed-pipe, substantially as described.

6. In a filter, the combination with the filter-casing having an inlet in its upper end and an outlet in its lower end, of a perforated diaphragm fitted in the upper part of the casing below the inlet, slitted tubes fitted at their upper ends in said perforations and closed at their lower ends, a collecting-chamber arranged in the lower end of the casing and communicating with the outlet, slitted tubes projecting upwardly from said collecting-chamber and closed at their upper ends, filter-beds arranged respectively above and below the diaphragm in the upper part of the casing, a valved discharge-pipe leading from the outlet, a feed-pipe leading from the discharge-pipe to the inlet, a service-pipe connected with said feed-pipe intermediate the ends of the latter, a three-way valve for diverting the water from the service-pipe to either branch of the feed-pipe, and a valved waste-pipe connected with the feed-pipe above said three-way valve, substantially as described.

7. In a filter, the combination with a filter-casing having an inlet in its upper end and an outlet in its lower end, and a collecting-chamber in its lower end communicating with said outlet, of a valved discharge-pipe leading from the outlet, a feed-pipe connected with one end of said discharge-pipe and at its other end with the upper end of the filter-casing, and provided with a valved waste-pipe, a service-pipe connected with the feed-pipe intermediate the ends of the latter, a three-way valve for diverting the water from the service-pipe to either branch of the feed-pipe or for shutting off the communication between said pipes altogether, a reservoir connected at its lower end by a valved communication with said service-pipe and at its upper end communicating by a pipe with the upper branch of the feed-pipe, a strainer arranged in the lower end of said reservoir, and a bed of iron filings supported on said strainer, substantially as described.

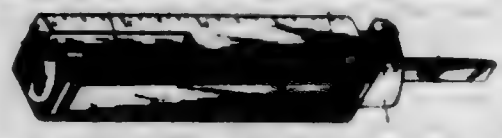
707,900. SHADE-HANGER. MARYLAND E. BOYCE, Baltimore, Md., assignor of one-half to Robert McClintock, Baltimore, Md. Filed June 6, 1902. Serial No. 110,655. (No model.)



Claim.—1. A vertically-adjustable shade-hanger, comprising two brackets arranged to receive the pintles of the shade-roller and each provided with two apertures, *b*, *b'*, and a socket, *c*; a rod inserted in said sockets whereby to connect one bracket with the other; eyes, *j*, *j''*, adapted to be secured to the window-frame; and a cord extending from one bracket to the other out through one aperture in said brackets and inwardly through the other aperture, one portion of said cord extending upwardly and inwardly through one eye, *j*, and screws to and through the other eye, *j''*, and the other portion of said cord passing upwardly and inwardly through the adjacent eye, *j''*, and connected to the first-named portion by a knot, whereby to limit the movement of the cord in one direction through said eyes, as set forth.

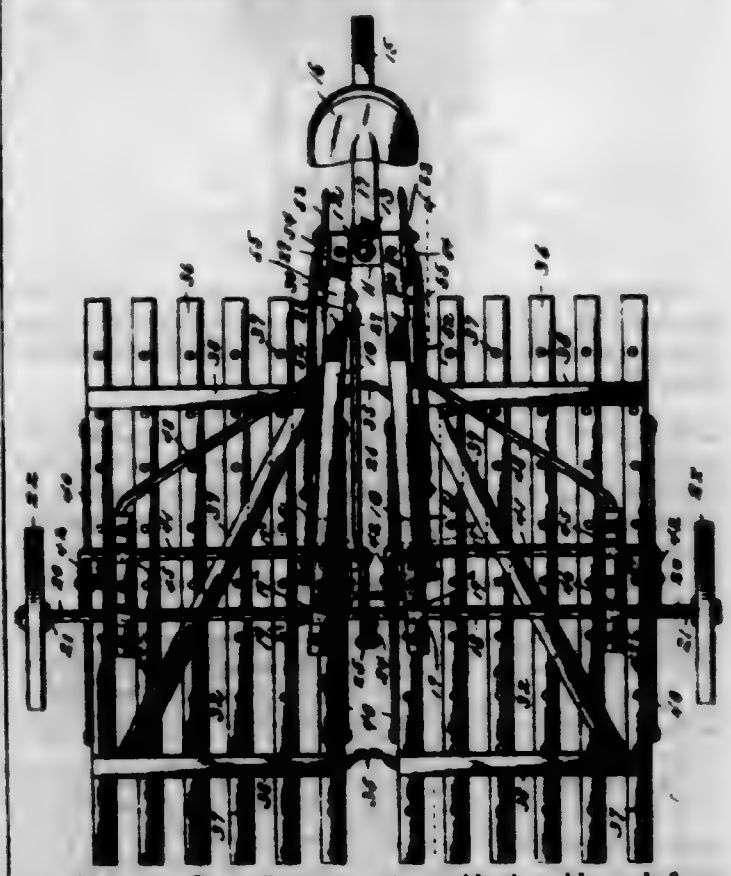
2. A vertically-adjustable shade-hanger, comprising two brackets arranged to receive the pintles of the shade-roller and each provided with two apertures, *b*, *b'*, and a socket, *c*, whose walls are surrounded by tongs, *d*, in two opposite of which are formed holes, *d'*; a rod inserted in said sockets; nails or screws passed through said holes, *d'*, into said rod; eyes, *j*, *j''*, adapted to be secured to the window-frame; and a cord extending from one bracket to the other out through one aperture in said brackets and inwardly through the other aperture, one portion of said cord extending upwardly and inwardly through one eye, *j*, and screws to and through the other eye, *j''*, and the other portion of said cord passing upwardly and inwardly through the adjacent eye, *j''*, and connected to the first-named portion by a knot, whereby to limit the movement of the cord in one direction through said eyes, as set forth.

707,901. STOCK FOR TOOLS. OWEN L. CHENEY, Bloomington, Ill. Filed Apr. 30, 1902. Serial No. 105,107. (No model.)



Claim.—A stock for holding a plurality of tools having a clamping-head at one end, and a series of longitudinally-extending seats at the opposite extremity which have an extent greater than a semicircle and open outwardly through the faces of the stock and the end of the latter opposite that carrying the clamping-head, the tools which are placed in the stock being of greater diameter than the width of the slots formed by the seats in relation to the faces of the stock, and a movable keeper for holding the tools in the seats, said keeper being provided with a slot to permit the tools to be withdrawn from the seats.

707,902. SULKY-HARROW. PAUL B. CHEMERINSKY, Sprockets Cal. Filed Nov. 20, 1901. Serial No. 83,026. (No model.)



Claim.—1. In a sulky-harrow, the combination with a main frame, of bearing-hangers 19ª secured thereto and provided with bearings 19 and 19ª, an arched axle journaled in the bearings 19, wheels mounted upon the axle, means for rocking the arched axle, bearing-hangers 46 supported by the arched axle and having bearings 45, brace-rods connecting the hangers 46 to the main frame, rock-shafts journaled in the bearings 19ª and 45, harrow-sections carried by the rock-shafts, and means for raising and lowering the harrow-sections independent of the wheels.

2. In a sulky-harrow, the combination with the machine-frame, of an arched axle connected therewith and having the forward carrying-wheels journaled thereon, bearing-hangers connected with said axle at one end having their opposite ends rigidly connected with the machine-frame,

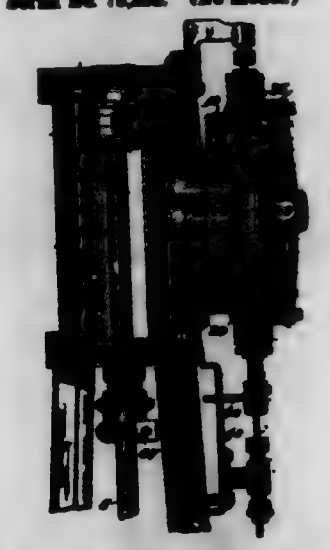
a plurality of harrow-sections suspended beneath the machine-frame, an individual rock-shaft for each harrow-section journaled in the bearing-hangers and pivotally connected with its respective harrow-section, and means for rocking said shaft independently of the movement of the arched axle, substantially as described.

3. In a sulky-harrow, the combination with the machine-frame, and an arched axle forming one of the supports for said frame, of a series of bearing-hangers mounted on the machine-frame and the arched axle, certain of said hangers being connected at the opposite ends directly with the machine-frame and others connected indirectly with the machine-frame by means of interposed braces, individual rock-shafts for each harrow-section journaled in the bearing-hangers, and means for operating each of said individual rock-shafts independently of any movement of the arched axle, substantially as described.

707,908. PROCESS OF CONVERTING WOOD INTO SUGAR. Alexander Classen, Aachen, Germany. Filed July 30, 1901. Serial No. 70,395. (Specimens.)

Claim.—A process of converting cellulose into sugar which consists in mixing one hundred parts by weight of the moist material with thirty to thirty-five parts of an aqueous solution of sulfurous acid, heating the mixture in a closed vessel at 120° to 145° centigrade for thirty to sixty minutes, blowing off the free sulfurous acid and finally lixiviating the mass with water, substantially as described.

707,904. ENGINE. Thomas Ogilby, Mount Savage, Md. Filed Oct. 10, 1901. Serial No. 78,202. (No model.)



Claim.—1. In an engine the combination with a cylinder, piston, and means of supply and exhaust, of automatic means of constricting the means of exhaust, alternately with each stroke of the piston, substantially for the purpose specified.

2. The combination with a cylinder and piston, a pair of ports communicating with the cylinder, and a supply-port and common exhaust, of a movable valve, means for alternately establishing communication between the two ports and the supply and exhaust, and means for constricting one of said ports each time it makes communication with the exhaust, substantially for the purpose specified.

3. The combination with a cylinder and piston, a pair of ports communicating with the cylinder, and a supply-port and common exhaust, of a movable valve, means for alternately establishing communication between the two ports and the supply and exhaust, and means for constricting one of said ports each time it makes communication with the exhaust, said means being adjustable independently of the movement of the valve, substantially for the purpose specified.

4. The combination with a cylinder, piston and valve-shell, of a pair of ports communicating with the bore of the shell, an exhaust communicating therewith, and a supply-port, of a valve provided with a longitudinal bore, movable within the bore of the shell, means of alternate communication between the supply-port and the ports of the cylinder around the bore of the valve, and means of alternate communication between the ports of the valve and the discharge-port through the bore of the valve.

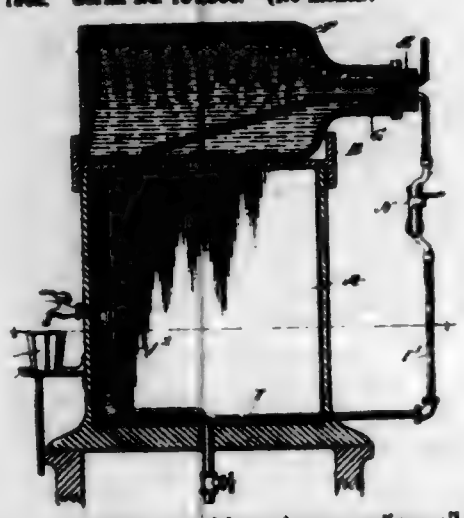
5. The combination with a cylinder, piston and valve-shell, of a pair of ports communicating with the bore of the shell, an exhaust communicating therewith, and a supply-port, of a valve provided with a longitudinal bore, movable within the bore of the shell, means of alternate communication between the supply-port and the ports of the cylinder around the bore of the valve, means of alternate communication between the ports of the valve and the discharge-port through the bore of the valve, and plugs within the bore of the valve carried by the shell, independent of the movement of the valve.

6. The combination with a cylinder, piston and valve-shell, of a pair of ports communicating with the bore of the shell, an exhaust communicating therewith, and a supply-port, of a valve provided with a longitudinal bore, movable within the bore of the shell, means of alternate communication between the supply-port and the ports of the cylinder around the bore of the valve, means of alternate communication between the ports of the valve, and independently-adjustable plugs within the bore of the valve carried by the shell independent of the movement of the valve.

7. The combination with a cylinder, piston and valve-shell, of a pair of ports communicating with the bore of the shell, an exhaust communicating therewith, and a supply-port, of a valve provided with a longitudinal bore movable within the bore of the shell, means of alternate communication between the supply-port and the ports of the cylinder around the bore of the valve, means of alternate communication between the ports of the valve and the discharge-port through the bore of the valve, and plugs within the bore of the valve carried by the shell, independent of the movement of the valve, and means for shifting the position of the valve by fluid-pressure derived from said supply-port.

8. The combination with a cylinder, piston and valve-shell, of a pair of ports communicating with the bore of the shell, an exhaust communicating therewith, and a supply-port, of a valve provided with a longitudinal bore movable within the bore of the shell, means of alternate communication between the supply-port and the ports of the cylinder around the bore of the valve, means of alternate communication between the ports of the valve and the discharge-port through the bore of the valve, plugs within the bore of the valve carried by the shell, independent of the movement of the valve, and means for shifting the position of the valve by fluid-pressure derived from said supply-port, said means being actuated by the movement of the piston-rod.

707,905. COOLER. Charles F. Conover, New York, N. Y. Filed May 15, 1902. Serial No. 107,360. (No model.)



Claim.—1. A cooler comprising a box, a cooling-coil therein, a receptacle, a stopper insertible in said receptacle, a siphon-pipe having a length arranged horizontally in said receptacle and inclined lengthwise thereof to a point close to the bottom of the same, said siphon-pipe extending through the stopper and communicating with the cooling-coil, and a vent-pipe extending through the stopper and inclined upwardly within said receptacle, the outer end of said vent-pipe being normally open for the free ingress of air to the upper part of the receptacle.

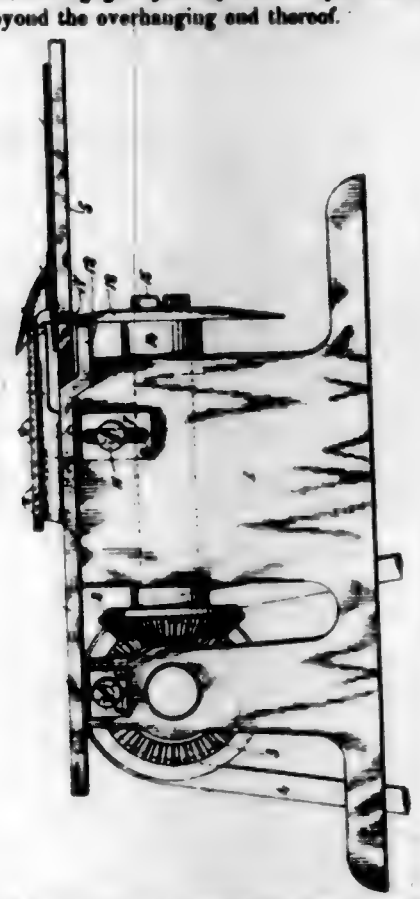
2. A cooler comprising a box, a cooling-coil therein, a support C on the top of the casing, a receptacle placed horizontally on the support, a stopper in the mouth of the receptacle, a siphon-pipe having an inclined length disposed within the receptacle and extended through the stopper, a flexible tube connecting the outer end of the siphon-pipe and the cooling-coil, a closing device on the flexible tube to compress the latter and cut off communication between the siphon-pipe and the cooling-coil, and a vent-pipe extending through the stopper and into the receptacle and having a normally open outer end.

3. A cooler comprising a box, a cooling-coil therein, a receptacle, a stopper for said receptacle, a siphon-pipe connected to said coil and extended through the stopper into the receptacle, and a vent-tube revolubly fitted in the stopper and having an inclined length within the receptacle and a normally open outer end, said vent-tube being adjustable in the stopper to bring its inclined length into close relation to a length of the siphon-pipe.

707,906. SHOE-LINING TRIMMER. Charleton B. Corwin, Jefferson City, Mo. Filed Mar. 6, 1902. Serial No. 96,906. (No model.)

Claim.—1. A shoe-lining trimmer, comprising a frame, a table, a revolvable cutter mounted on the frame, a cutting-block mounted on the table and having an undercut overhanging end forming a space between

itself and the table, and a gage adjustably secured upon said cutting-block and extending beyond the overhanging end thereof.



2. A shoe-lining trimmer, comprising a frame, a table, a revoluble cutter mounted on the frame and a cutting-block and a gage both mounted on the frame adjacent to said revoluble cutter and adjustable relatively thereto, said cutting-block having an undercut overhanging end forming a space between itself and the table, and said gage extending beyond said overhanging end of the cutting-block.

3. A shoe-lining trimmer, comprising a frame, a table, a revoluble cutter mounted on said frame, means for adjusting said table relatively to said cutter, a cutting-block mounted on said table and provided with an overhanging end forming a space between itself and the table, said end of the cutting-block terminating in an angular edge which is in opposing relation to the face of the cutter, and means whereby said block may be adjusted relatively to said revoluble cutter to vary the distance between the angular edge of the block and the face of the cutter.

4. A shoe-lining trimmer, comprising a frame, a revoluble cutter mounted thereon, a table, a cutting-block adjustably secured to said table, said cutting-block being provided with an overhanging end forming a space between itself and the table, and said end terminating in an angular edge, means whereby said cutting-block may be adjusted relatively to the face of said cutter, and a gage projecting over the overhanging end of the cutting-block and beyond the angular edge thereof.

5. A shoe-lining trimmer, comprising a table, a revoluble cutter mounted adjacent thereto, a cutting-block to be secured upon said table, said cutting-block being provided with an angular edge, and a gage provided with a substantially spoon-shaped end to be secured upon said cutting-block, the arrangement being such that said gage overhangs said cutter and is adjustable relatively thereto.

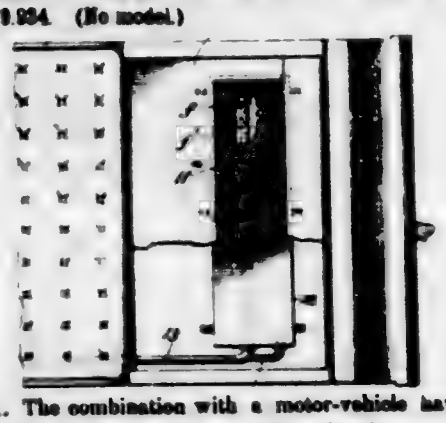
6. A shoe-lining trimmer, comprising a table, a revoluble cutter mounted adjacent thereto, a cutting-block to be secured upon said table, said cutting-block being provided with an angular edge, a gage mounted upon said cutting-block and provided with a downwardly-projecting end overhanging the edge of said cutter, and means for adjusting the height of the table relatively to the operating edge of said cutter.

7. A shoe-lining trimmer, comprising a table, a revoluble cutter mounted adjacent thereto, a cutting-block provided with an angular surface and also provided with a mutilation adjacent to said surface, and means for adjustably securing said cutting-block upon said table, the arrangement being such that said cutting-block may be so adjusted as to present said angular edge immediately adjacent to said revoluble cutter by leaving a vacant space between said angular surface and said table.

707,907. METHOD OF RETTING RAMIE OR SIMILAR FIBER. EUGÈNE DEPETRO, Paris, France. Filed May 26, 1902. Serial No. 109,094. (No specimens.)

Claim.—The process for removing from the fibers of ramie, aloes, wood and the like incrusting matters such as gums and the like, which consists of treating these bodies with natural sea-water or with a solution of salts prepared so as to have nearly the composition of the sea-water substantially as described.

707,908. FOOT-WARMER FOR VEHICLES. GEORGE W. DUNHAM and JOHN W. FOX, East Cleveland, Ohio. Filed Oct. 26, 1901. Serial No. 79,934. (No model.)



Claim.—1. The combination with a motor-vehicle having a protected aperture in its footboard, of a receiving-chamber, means for suspending the receiving-chamber from the footboard below the aperture thereof, a pipe leading to the receiving-chamber for supplying a heating medium to said chamber, and a pipe leading from said chamber and extending rearwardly to discharge the spent heating medium at the rear of the vehicle, as set forth.

2. A foot-warmer for vehicles, comprising a rectangular plate-metal receiver, adapted to be hung in an opening in the footboard of the vehicle, two two-way valves hung with nipples below corresponding openings in the bottom of the receiver at opposite ends thereof, a by-pass pipe connected by fittings upon like ends of the valves, a conduit-pipe for a heating agent engaging the other end of one of the two-way valves, and an escape-pipe extending from the corresponding end of the other two-way valve.

3. The combination with a vehicle having an aperture in its footboard, of a receiving-chamber having a top plate extending beyond the chamber and resting upon the footboard, nipples projecting from the bottom of the chamber at opposite ends thereof, a two-way valve connected with each nipple, a by-pass pipe connected with one end of the said valves, a conduit-pipe connected with the other end of one of the two-way valves, and an escape-pipe connected with the corresponding end of the other two-way valve, as set forth.

707,909. SOUND-MODIFIER. NELSON C. DURAND, Scranton, Pa., assignor to International Text Book Company, Scranton, Pa., a Corporation of Pennsylvania. Filed June 14, 1902. Serial No. 111,673. (No model.)

Claim.—1. The combination of a divided sound-conveyer, and a perforated tube interposed therein.

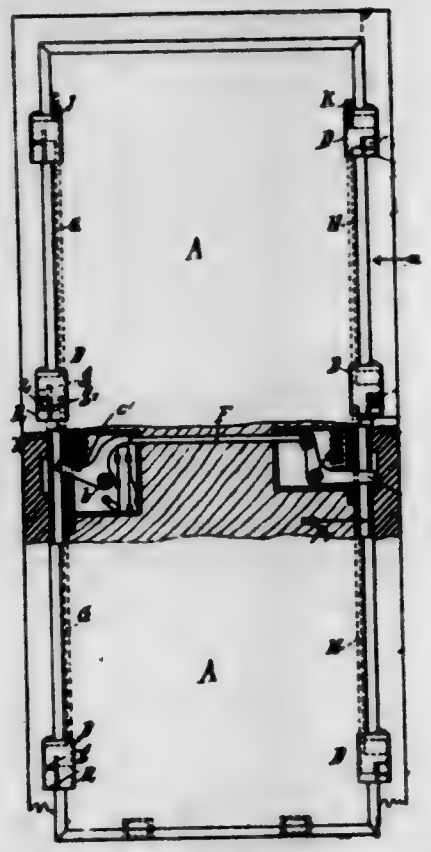
2. In combination with a divided sound-conveyer, a perforated tube interposed therein, said conveyer being adjustable on said tube to regulate the escape of sound from the conveyer.

707,910. RIGHT AND LEFT OPENING DOOR. FERDINAND FISCHER and LUDWIG KIEFER, Carlsruhe, Germany. Filed Aug. 4, 1902. Serial No. 118,187. (No model.)

Claim.—1. The combination with the door and its frame provided with sockets, having an L-shaped opening, of bell-crank latches pivotally connected to said door, springs carried by the door and bearing against one arm of each of the bell-crank latches for normally retaining them in a latching position, vertically-adjustable rods arranged in the door-frame and operated by the said latches when the latter are operated, pins forming pivots carried by the rods and adapted to engage in the said sockets when the door is opened in one direction or the other, and hook-like projections carried by the rods and adapted to be passed through the L-shaped openings when the rods and door are operated.

2. The combination with the door and its frame provided with sockets, provided with a vertically and laterally extending opening, of bell-crank latches pivotally connected to said door, springs carried by the door and bearing against one arm of each of the bell-crank latches for normally retaining them in a latching position, vertically-adjustable rods arranged in the door-frame and operated by the said latches when the latter are operated, pins forming pivots carried by the rods and adapted to engage in the said sockets when the door is opened in one direction or

the other, and means carried by the rods and adapted to operate in the said openings to permit of the disengagement of the acting pivots during the opening or closing of the door.



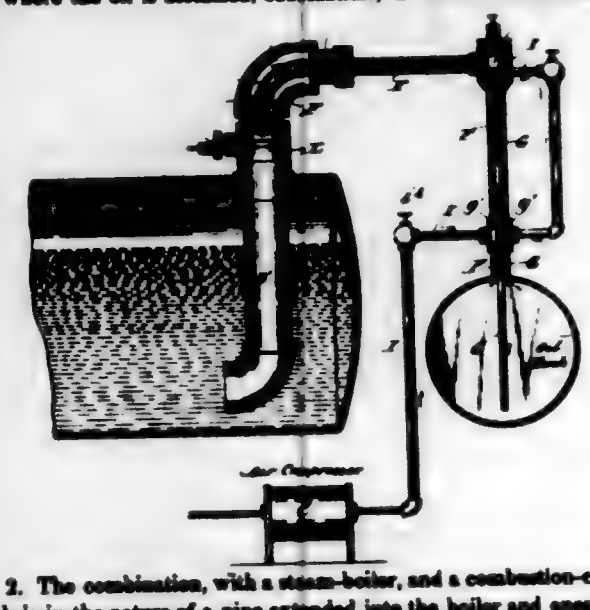
3. The combination with the door and its frame provided with sockets, provided with L-shaped openings, of bell-crank latches pivotally connected to said door, springs carried by the door and bearing against one arm of each of the bell-crank latches for normally retaining them in a latching position, vertically-adjustable rods arranged in the door-frame and operated by the said latches when the latter are operated, pins forming pivots carried by the rods and adapted to engage in the said sockets when the door is opened in one direction or the other, hook-like projections carried by the rods and adapted to operate in said openings to permit the disengagement of the acting pivots during the opening or closing of the door, a rod pivotally connected to one end of one arm of one of the bell-crank latches and adapted to bear against one arm of the other of the said bell-crank latches to prevent the simultaneous operation of the said latches, and means for operating said latches.

4. The combination with the door and its frame provided with sockets, of bell-crank latches pivotally connected to said door, springs carried by the door and bearing against one arm of each of the bell-crank latches for normally retaining them in a latching position, vertically-adjustable rods arranged in the door-frame and operated by the said latches when the latter are operated, lugs forming pivots carried by the rods and adapted to engage in the said sockets when the door is opened in one direction or the other, means carried by the rods and adapted to permit the disengagement of the acting pivots during the opening or closing of the door, a rod pivotally connected to one end of one arm of one of the bell-crank latches and adapted to bear against one arm of the other of the said bell-crank latches to permit the simultaneous operation of the said latches, means for operating said latches, and means carried by the rods to permit of closing the door independently of the operating means for the latches.

5. A right and left opening door having slide-rods G and H, hinge-pins and lugs carried by the rods, and hinge-knuckles having longitudinal and lateral cuts, said pins when lifted by the rods clearing the knuckles and said lugs when lifted passing through the longitudinal to the lateral or clearing cut so as to leave the adjacent edge of the door free to open, and said lugs when the hinge-pins are not lifted being made to swing or move under the knuckles to prevent the adjacent edge of the door lifting out of place.

707,911. COMBUSTION APPARATUS FOR STEAM-BOILERS. Joseph R. Fraser, Dayton, Ohio. Filed Oct. 24, 1901. Serial No. 79,328. (No model.)

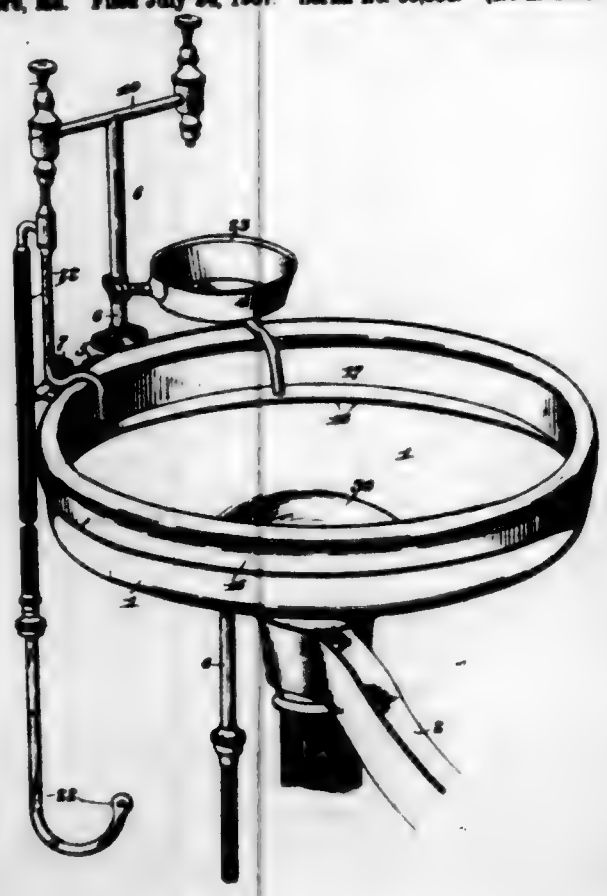
Claim.—1. The combination, with a steam-boiler, of the furnace attachment described, the same comprising an air-compressor, an oil-tank having a pipe extending therefrom, an air-pipe connecting the tank with the compressor, whereby air-pressure is applied upon the surface of the oil, a combustion-chamber, or fire-box, extending into the boiler and opening below the normal water-level therein, an air-pipe arranged in the fire-box, and an oil-pipe within the air-pipe, both having nozzles, located in the upper portion of the combustion-chamber, which are provided with coincident end openings for escape of air and oil, and an electrical igniting device arranged in the combustion-chamber directly below the air-pipe, where the oil is atomized, substantially as shown and described.



2. The combination, with a steam-boiler, and a combustion-chamber which is in the nature of a pipe extended into the boiler and opening below the normal water-level therein, of an electrical igniter, an air-pipe terminating just above the igniter, and an oil-discharge pipe having its nozzle within the air-pipe, the two pipes being separated by a space which allows the free passage of air, the air-pipe having lateral discharge-openings for supporting combustion, and means for forcing air and oil to such burner, substantially as shown and described.

3. The combination with a steam-boiler, a furnace attachment comprising a fuel-combustion chamber projecting into the boiler and opening below the normal water-level therein, of an electrical igniter arranged in the upper portion of said chamber, an air-pipe entering such chamber and terminating at a point adjacent to the igniter where it is provided with discharge-openings, an oil-pipe arranged within the air-pipe and separated therefrom by a space which allows the free passage of air and provided at its terminal with an opening for allowing escape of oil so that it may be carried out of the air-pipe and atomized as described, a series of valves applied to the said air and oil pipes for controlling the passage of the respective fluids therein, the oil-tank with which the air-pipe connects and into which the air-pipe projects to a point near the bottom thereof, and an air-compressor for maintaining in the tank and in the oil-pipe a pressure greater than the steam-pressure in the boiler, substantially as shown and described.

707,912. FOUNTAIN-SPITTOON. Chester M. Freeman, Baltimore, Md. Filed July 24, 1901. Serial No. 69,558. (No model.)



Claim.—1. A flushing-spittoon, comprising a bowl, an annular projection inside the bowl for distributing liquids evenly over the surface thereof, a flushing-pipe arranged within the bowl above said projection and provided with a series of apertures for directing streams of water against the surface of the bowl, the said apertures being arranged in radial lines and delivering streams against the bowl before they spatter or break, the arrangement of the apertures assisting in the proper spreading of the liquid upon the bowl-surface, together with the annular projection, substantially as described.

2. A flushing-spittoon, comprising a bowl, a flushing-tube arranged within the same and provided with a series of radially-located discharge-apertures for directing streams of water against the bowl from the inside thereof, and an annular spreading projection upon the inner surface of the bowl below the flushing-tube to coöperate with the arrangement of the apertures in the tube for perfectly covering every portion of the surface of the bowl with water and without noise, substantially as described.

3. A flushing-spittoon, comprising a bowl, a flushing-pipe extending into the bowl at the upper edge thereof, its inner end being located upon the entering portion of the said tube, the said tube having a series of discharge-apertures arranged to deliver streams of water against the inner surface of the bowl at an angle of about thirty-five degrees, and a spreading rib or projection inside the bowl for further distributing the water on the surface of the bowl, substantially as described.

4. A fountain-spittoon for dental purposes, comprising a bowl adapted to discharge into a suitable outlet, a removable rim inclosing the upper edge of the said bowl and lying against the inner surface thereof, a flushing-tube supported inside the said removable rim, and an upper overhanging inclosing rim for covering the said inner rim and the flushing-tube, substantially as described.

5. A fountain-spittoon comprising a discharging-bowl, a removable inner rim carrying projections extending into the bowl, a flushing-tube resting on the said projections and adapted to deliver water or other liquid within the bowl, and an outer inclosing rim for overhanging and covering the said removable rim so as to be supported in position thereby, said tube being the flushing-tube, substantially as described.

6. A flushing-spittoon, comprising a discharging-bowl, means for delivering water or other liquid within the said bowl, and means for evenly distributing the said liquid over the entire inner surface of the bowl, comprising an inwardly-projecting annular flange or rib arranged within the bowl beneath the water-supply, substantially as described.

7. A flushing-spittoon, comprising a discharging-bowl, and a water-supply at its upper edge, a wire arranged within the bowl beneath the water-supply so as to form an inwardly-projecting rib for thoroughly spreading and distributing the water over the surface of the bowl, substantially as described.

8. A flushing-spittoon, comprising a bowl, and a flushing-tube arranged within the upper part thereof, an annular rib or projection supported on the inner surface of the bowl at a suitable distance below the discharge-pipe, whereby all the water entering the bowl will be forced to run over the said rib, and will thereby be thoroughly distributed over the surface of the bowl, substantially as described.

9. A flushing-spittoon, comprising a bowl, a removable rim inclosing its upper edge and projecting into the same, a flushing-pipe arranged within the said rim for delivering water into the bowl, and an annular flange carried by the lower edge of the said removable rim inside the bowl for spreading water over the surface of the bowl, substantially as described.

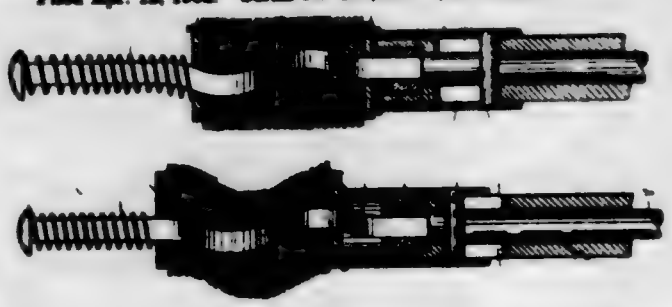
10. A flushing-spittoon, comprising a bowl, a flushing-tube entering the same at the upper portion thereof, and entering in curved lines, the inner end extending around the bowl and lapping the tube where it enters the bowl, a plug closing the inner end of the tube, the lapping arrangement of the said tube facilitating the removal and insertion of said plug, while the coiling of the pipe in the bowl facilitates its being sprung into position, substantially as described.

11. A flushing-spittoon, comprising a bowl, an annular projection inside the bowl for distributing liquids evenly over the surface thereof, a flushing-pipe arranged within the bowl and provided with a series of apertures for directing streams of water against the surface of the bowl, the said apertures being arranged in radial lines and delivering streams against the bowl before they spatter or break, the arrangement of the apertures assisting in the proper spreading of the liquid upon the bowl-surface, together with the annular projection, substantially as described.

12. A flushing-spittoon, comprising a bowl, a flushing-tube arranged within the same and provided with a series of radially-located discharge-apertures for directing streams of water against the bowl from the inside thereof, and an annular spreading projection upon the inner face of the bowl to coöperate with the arrangement of the apertures in the tube for perfectly covering every portion of the surface of the bowl with water

707,918. GUN-CLEANER. GEORGE H. GARRISON, Ruceda, Wash.

Filed Apr. 12, 1902. Serial No. 102,552. (No model.)



Claim.—1. In a gun-cleaner, a swab, and a resilient vermicular core extended lengthwise through the swab, substantially as specified.

2. In a gun-cleaner, a swab, a vermicular core on which the swab is mounted, and means for moving the swab lengthwise of the core, whereby the swab may be caused to take the form of the core to increase its diameter, substantially as specified.

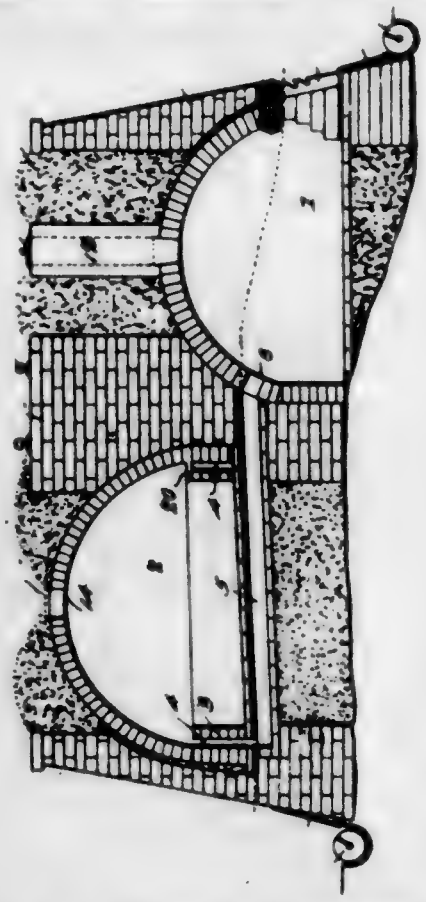
3. In a gun-cleaner, a swab formed of a plurality of disks, a vermicular spring-yielding core in the swab, and means for moving the swab lengthwise of the core, whereby the disks may be thrown out of alinement to increase the diameter of the swab, substantially as specified.

4. In a gun-cleaner, a swab consisting of disks formed of metal fabric, a vermicular core extended through the swab, a disk on the end of the swab having an opening, the core being extended through the opening, a spring arranged between said disk and a head on the end of the core, and means at the opposite end of the swab for moving it on the core to force the disks out of alinement, substantially as specified.

5. In a gun-cleaner, a tubular rod, a push-rod movable therein, a sleeve movable on the end of the tubular rod and adapted to be moved by the push-rod, a perforated disk arranged loosely on the end of the sleeve, a vermicular core extended through the perforation of the disk, a swab material on said core, a perforated disk engaging with the outer end of the swab and through which the core passes, and a spring arranged between said last-named disk and a head on the end of the core, substantially as specified.

707,914. COKE-OVEN. WILLIAM T. GATES, Simpson, W. Va.

Filed Mar. 31, 1902. Serial No. 100,806. (No model.)



Claim.—1. An apparatus for producing different grades of coke comprising a plurality of ovens, and means for conveying the products of combustion from a point above the floor of an oven producing a lower grade of coke into and beneath the floor of an oven producing a higher grade of coke.

2. An apparatus for producing different grades of coke, comprising a plurality of ovens, and means for conveying the products of combustion from a point above the floor of an oven producing a lower grade of coke

into and beneath the floor and around the sides of an oven producing a higher grade of coke.

3. An apparatus for producing different grades of coke, comprising a plurality of ovens, the floor of an oven producing a lower grade of coke being disposed below the plane of the floor of an oven producing a higher grade of coke, and means for conveying the products of combustion from the first-named to the last-named oven.

4. An apparatus for producing different grades of coke, comprising a plurality of ovens, and a tortuous duct for conveying the products of combustion from a point above the floor of an oven producing a lower grade of coke into and beneath the floor of an oven producing a higher grade of coke.

5. An apparatus for producing different grades of coke, comprising a plurality of ovens, a tortuous duct for conveying the products of combustion from a point above the floor of an oven producing a lower grade of coke into and beneath the floor of an oven producing a higher grade, and a flue communicating with the duct for conveying the said products around the walls of the last-named oven.

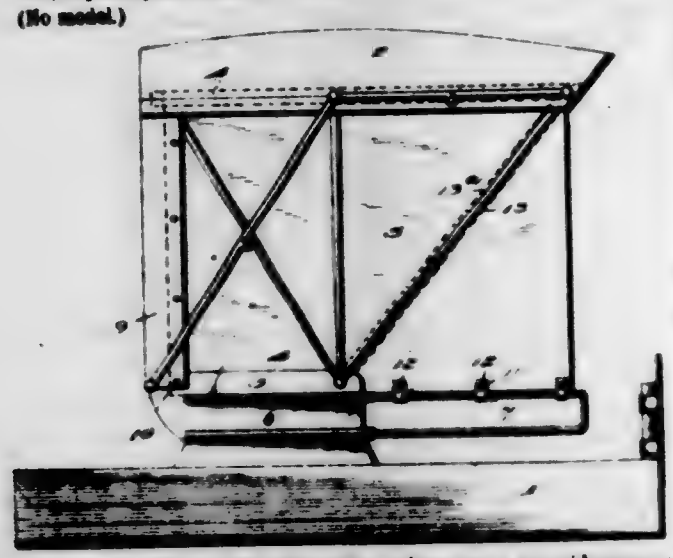
6. An apparatus for producing different grades of coke, comprising a plurality of ovens, a tortuous duct for conveying the products of combustion from a point above the floor of an oven producing a lower grade of coke into and beneath the floor of an oven producing a higher grade, and a flue communicating with the duct for conveying the said products around the interior wall of the last-named oven.

7. An apparatus for producing different grades of coke, comprising two ovens arranged back to back and having their floors arranged on different planes, a tortuous duct arranged beneath the floor of the higher oven and communicating with the lower oven at a point above its floor, and a flue communicating with the duct for conveying the said products around the wall of the higher oven.

8. An apparatus for producing different grades of coke, comprising two ovens arranged back to back and having their floors arranged on different planes, and a tortuous duct arranged beneath the floor of the higher oven and communicating with the lower oven at a point above its floor

---

707,915. CARRIAGE TOP AND CURTAIN. WILLIAM B. GLEBE, Crystalsprings, Kans. Filed June 3, 1902. Serial No. 110,099. (No model.)



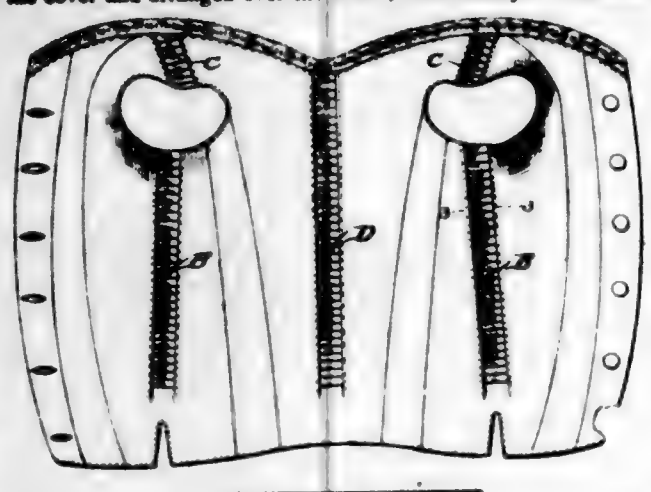
Claim.—1. The combination with a vehicle-seat; of guideways arranged on the end thereof; a frame or support adjustably supported within said guideways; and a curtain adapted to be attached at its lower edge to said support; and means for rolling said curtain after it is detached from the frame or support.

2. The combination with a vehicle seat and top; of guideways arranged on the ends of the seat; frames or supports adjustably supported within said guideways; curtain-rollers pivotally supported at one end, whereby the rollers may be turned down after the curtains have been rolled up.

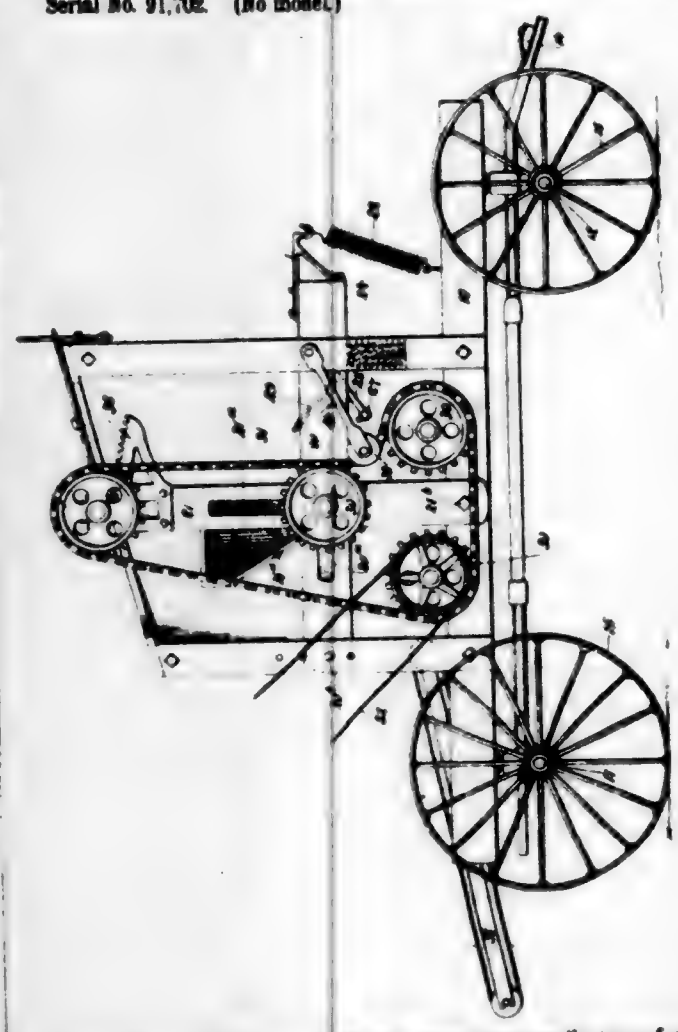
3. The combination with a vehicle seat and top; of parallel guideways arranged on the ends of the seat; frames each comprising a rod bent to U shape, adjustably supported within said guideways; curtain-rollers pivotally supported at one end; curtains on said rollers, and means for detachably securing the curtains to the frames and vehicle-top.

707,916. CORSET-COVER. WILLIAM GOLDSTEIN, New York, N. Y. Filed Mar. 8, 1901. Serial No. 50,452. (No model.)

Claim.—As an article of manufacture, a corset-cover, having at its side and back seams provided with a plurality of transversely-arranged strips, of elastic material, said strips extending from the upper edge of the cover to within a distance from the lower edge thereof, and having a reinforcing and protecting strip of plaited fabric secured to the inside of the cover and arranged over the seams, substantially as described.



707,917. BALING-PRESS. THADEUS A. GOODWYN, Madill, Ind. Ter., and PHILLIP R. STOVALL, Waxahachie, Tex. Filed Jan. 29, 1902. Serial No. 91,702. (No model.)



Claim.—1. A baling-press, having three baling-rolls, two of which are mounted in stationary bearings and the third of which is movable toward and from the center of the bale to accommodate the increasing size thereof, a swinging beam engaged with the axis of the third roll to press the same inward toward the bale, means for actuating the beam, and gearing for uninterruptedly driving the rolls.

2. A baling-press, comprising a roll working against the bale, two longitudinally-slotted levers receiving the journals of the roll in the slot thereof, whereby to allow the roll transverse movement longitudinally of the levers, for the purpose specified, and means pressing against the lever to hold the roll in operative position.

3. A baling-press, comprising a roll adapted to press against a bale, crossing levers having sliding connection with the axis of the roll, means pressing on one lever to hold the roll in operative position, and means for throwing the other lever sidewise to release the bale.

4. A baling-press, comprising a roll adapted to press against a bale, crossing levers having sliding connection with the axis of the roll, means pressing on one lever to hold the roll in operative position, and means for throwing the other lever sidewise to release the bale, said means comprising a toothed sector on the lever, a pinion meshed therewith, and means for throwing the pinion into and out of action.

5. A baling-press, comprising a roll adapted to press against a bale,

crossing levers having sliding connection with the axis of the roll, means pressing on one lever to hold the roll in operative position, means for throwing the other lever sidewise to release the bale, said means comprising a toothed sector on the lever, a pinion meshed therewith, and means for throwing the pinion into and out of action, said means for throwing the pinion into and out of action being in the path of movement of the first-named lever, to be actuated thereby.

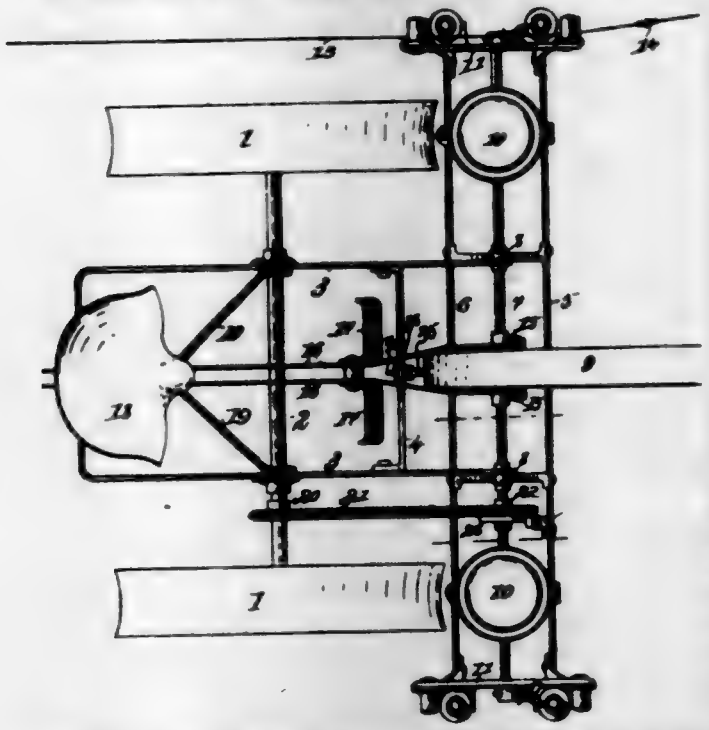
6. A baling-press, comprising a roller bearing on the bale, crossing levers each having sliding connection with the axis of the roller, means bearing on one lever to press the roller into operative position, means for throwing the other lever sidewise for the purpose specified, and operating devices for said other lever, the operating devices being arranged in the path of the first-named lever to be actuated thereby.

7. A baling-press, having a roll adapted to bear on a bale, crossing levers each having sliding connection with the roll, means bearing on one lever to hold the roll against the bale, and means for removably holding the other lever in fixed position.

8. A baling-press, comprising three rolls, two of which are mounted in relatively stationary bearings, crossing levers having sliding connection with the third roll, means bearing on one lever to hold said roll against the bale, and means for removably holding the second lever in fixed position.

9 A baling-press, comprising a roll adapted to bear against a bale, two members movable in crossing lines, said members having connection with the axis of the roll, means for pressing one member to hold the roll in operative position, and means for throwing the other members sidewise to release the bale.

707,918. CHECK-ROW PLANTER. LEVI P. GRAHAM, Decatur, Ill. Filed July 3, 1902. Serial No. 114,207. (No model.)



Claim.—1. In a check-row planter, the combination of a rear frame mounted on wheels, a front frame provided with planting mechanism and pivotally conjoined with the rear frame, a rock-shaft in the front frame, means for transmitting motion from a wheel of the rear frame to rock the shaft in one direction, and a connection between the rock-shaft and the rear frame adapted to lift upward on the front frame when the rock-shaft is rocked by the wheel.

2. In a check-row planter, the combination of a rear frame mounted on wheels, a front frame provided with planting mechanism and pivotally conjoined with the rear frame, a rock-shaft in the front frame, means for transmitting motion from a wheel of the rear frame to rock the shaft in one direction, an arm on the rock-shaft, and a connection between the arm and the rear frame adapted to lift upward on the front frame when the rock-shaft is rocked by the wheel.

3. In a check-row planter, the combination of a rear frame mounted on wheels, a front frame provided with planting mechanism and pivotally conjoined with the rear frame, a rock-shaft in the front frame, means for transmitting motion from a wheel of the rear frame to rock the shaft in one direction, an arm on the rock-shaft, a link pivotally connected with the arm on the rock-shaft and forming with the arm a dead-center lock when the front frame is raised, and a connection between the link and the rear frame whereby the front frame is lifted when the shaft is rocked by the wheel.

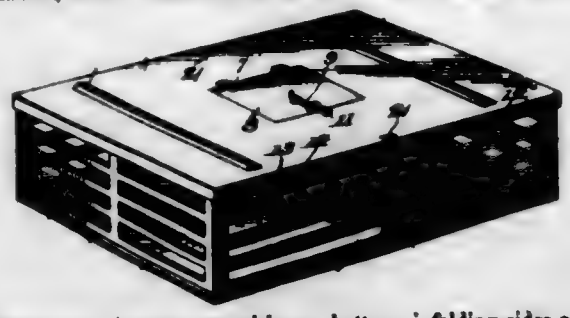
4. In a check-row planter, the combination of a rear frame mounted on wheels, a front frame provided with planting mechanism and pivotally conjoined with the rear frame, a rock-shaft in the front frame, means for transmitting motion from a wheel of the rear frame to rock the shaft in one direction, an arm on the rock-shaft, a lever fulcrumed in the front frame a link connecting an end of the lever with the arm on the rock-shaft, and a connection between the other end of the lever and the rear frame back of the pivotal conjunction of the two frames.

5. In a check-row planter, the combination of a rear frame mounted on wheels, a front frame provided with planting mechanism and pivotally conjoined with the rear frame, a rock-shaft in the front frame, means for transmitting motion from a wheel of the rear frame to rock the shaft in one direction, a connection between the rock-shaft and the rear frame adapted to lift upward on the front frame when the shaft is rocked by the wheel, and a forked lever connected with the shaft and adapted to be actuated by knots on a check-row wire.

6. In a check-row planter, the combination of a rear frame mounted on wheels, a front frame provided with planting mechanism and pivotally conjoined with the rear frame, a rock-shaft in the front frame, means for transmitting motion from a wheel of the rear frame to rock the shaft in one direction, a connection between the rock-shaft and the rear frame adapted to lift upward on the front frame when the shaft is rocked by the wheel, an arm on the rock-shaft extending forward and downward when the front frame is raised and extending forward and upward when the front frame is lowered, and a seat-carrying bar pivotally connected at its front end with the arm of the rock-shaft.

7. In a check-row planter, the combination of a rear frame mounted on wheels, a front frame provided with planting mechanism and having up-and-down motion, means for actuating the seed-dropping mechanism of the front frame simultaneous with the fall of the front frame, and means, set in motion by the fall of the front frame, for raising the front frame by force derived from a wheel of the rear frame.

707,919. FOLDING CRATE. SHERMAN GREER and JAMES H. GORE, Lincoln, Nebr. Filed Dec. 30, 1901. Serial No. 87,775. (No model.)



Claim.—1. A crate comprising a bottom, infolding sides and ends secured to said bottom and slatted, the sides having central bars projected at their free terminals beyond the width of said sides, a top of imperforate construction having a surrounding rim and provided with slots therein adjacent the opposite sides to removably receive the projected ends of the said bars, the top also having a central door-opening supplied with a hinged closure, and spring-catches secured to the inner portions of the sides of the rim and provided with lower inturned angular ends to engage the upper rails of the sides of the crate or the under portion of the bottom.

2. A crate comprising a bottom, infolding slatted sides and ends hinged to said bottom, the sides having central vertically-disposed bars which are extended at their upper extremities, a top having a surrounding rim and raised ribs on the upper surface adjacent the opposite ends extending transversely of the top, the bottom also having similar transverse ribs near the opposite ends, and spring-catches secured to the top and housed within the rim and adapted to engage under the lower edges of the uppermost slats of the sides or the under portion of the bottom, the top also having slots at the center near the opposite sides to removably receive the projected ends of the bars.

707,920. PNEUMATIC HAMMER. CHARLES H. HAMBLER, Philadelphia, Pa. Filed June 20, 1901. Serial No. 65,342. (No model.)

Claim.—1. In a pneumatic hammer, the combination of a handle provided with a cylindrical portion having an internal screw-thread and a larger portion having an internal screw-thread of the opposite pitch, with a cylinder having a screw-threaded end adapted to engage the smaller screw-thread in the handle, and a nut adapted to engage the larger screw-thread in the handle.

2. In a pneumatic hammer, the combination of a handle provided with a cylindrical portion having an internal right-handed screw-thread and a larger internal left-handed screw-thread, of a cylinder having an enlarged end provided with a right-handed screw-thread and a circular nut having a left-handed screw-thread adapted to engage with the left-handed screw-threads in the handle.

3. In a pneumatic hammer, the combination of a handle provided with a cylindrical portion having internal right-handed screw-threads and a larger portion having internal left-handed screw-threads, with a cylinder having an enlarged end forming a shoulder, said end being provided with right-handed screw-threads, and a circular nut surrounding said cylinder and provided with left-handed threads, said nut screwing into the left-handed screw-threads on said handle and abutting against the shoulder on said cylinder, and means for preventing the rotation of said nut.

4. In a pneumatic hammer, the combination of a handle, a cylinder screwed therein, a circular nut screwed into said handle to prevent disengagement of said cylinder and said handle, said nut being provided with internal teeth at one end, and means engaging said teeth to prevent the rotation of said nut.

5. In a pneumatic hammer, the combination of a handle, a cylinder and a circular nut holding said handle and cylinder together, said nut being provided with internal teeth at one end, and a toothed dog located in a slot in said cylinder and engaging said nut.

6. In a pneumatic hammer, the combination of a handle, a cylinder and a circular nut holding said handle and cylinder together, said nut being provided with internal teeth at one end, with a spring-operated toothed dog located in a slot in said cylinder and engaging said nut.

7. In a pneumatic hammer, the combination of a handle provided with a cylindrical portion having an internal screw-thread, a cylinder screwed therein, a circular nut engaging said handle and said cylinder, said nut being provided with internal teeth at one end with a toothed dog located in a slot in said cylinder and engaging said nut, and a spring for normally holding said dog and said nut in engagement, said dog being provided with pins.

8. In a pneumatic hammer, the combination of a handle, a cylinder provided with a shoulder and screw-threaded into said handle and a circular nut confining said handle and said cylinder together, said nut being provided with internal teeth at one end, with a toothed dog adapted to normally engage said nut and prevent its rotation, and means whereby said dog may be held out of contact with said nut.

9. In a pneumatic hammer, the combination of a handle, a cylinder and a nut confining said handle and cylinder together, said nut being provided with internal teeth at one end, and said cylinder being provided with a cylindrical slot, a larger circular slot, and smaller vertical slots, with a toothed dog provided with pins located in said cylindrical slot, and a spring engaging said dog and tending to force it into engagement with said nut.

10. In a pneumatic hammer, the combination of a cylinder and a sliding valve therefor, said valve being moved in one direction by the jar of the hammer when it is operated, and in the other direction by the compression of the air in said cylinder consequent upon the return stroke of the piston.

11. In a pneumatic hammer, the combination of a cylinder, a sliding cylindrical valve located at one end of said cylinder, said valve being provided with ports and a piston, the ports being so arranged that the valve is moved in one direction by the jar of the hammer in its operation, and in the opposite direction by the compression of the air incident to the return stroke of the piston.

12. In a pneumatic hammer, the combination of a cylinder open at both ends, a tool closing one end of said cylinder and a handle closing the other end, the bore of said cylinder having an enlargement at one end, a sliding cylindrical valve located in said enlargement and a piston in said cylinder, the parts being so arranged that the valve is slid in one direction by the impact of said piston upon said tool, and whereby the valve is slid in the other direction by the return stroke of the piston.

13. In a pneumatic hammer, the combination of a cylinder the bore thereof having an enlargement at one end, said cylinder being provided with air-passages, a sliding cylindrical valve provided with ports located in said enlargement and a piston in said cylinder, the air-passages, ports and cut-away portions of said valve and cylinder being so arranged that the valve is moved in one direction by the jar of the hammer as it is operated, and moved in the other direction by the compression of the air incident to the return stroke of the piston.

14. In a pneumatic hammer, the combination of a cylinder, a piston therein and means for supplying a motor fluid thereto to move said piston back and forth, including a sliding cylindrical valve provided with ports and located in said cylinder, said cylinder being provided with an opening running from the bore thereof to the outer air and located near one end thereof, whereby the pressure of the motor fluid upon the piston will be considerably diminished just before the piston strikes the tool.

15. In a pneumatic hammer, the combination of a cylinder provided with air-passages and a stepped cylindrical bore, a piston in said cylinder and a sliding stepped cylindrical valve located in one end of said cylinder, said valve being provided with air openings and ports, and the parts being so arranged that the valve is moved in one direction by the impact when the hammer is in operation, and is moved in the other direction by the compression of the air in the bore of the said cylinder caused by the return stroke of said piston.

16. In a pneumatic hammer, the combination of a handle, a cylinder secured thereto, a piston and a valve located in said cylinder, of an air-passage in said handle, a valve normally closing said air-passage, and means for positively locking said valve in said closed position.

17. In a pneumatic hammer, the combination of a handle provided with an air-passage, a cylinder secured to said handle provided with air-passages, a piston in said cylinder, a heavy cylindrical valve provided with air-ports in said cylinder, a valve for cutting off the air in the air-passage of said handle, means for positively locking said valve in its closed position, and means for releasing said valve from its locked position.

18. In a pneumatic hammer, the combination of a handle provided with an air-passage, a cylinder provided with air-passages secured to said handle, a valve provided with air-ports located in said cylinder, a piston in said cylinder, a valve normally closing the air-passage in said handle, means for positively locking said valve in its closed position, and means operable by the hand of the workman for releasing and operating said valve.

19. In a pneumatic hammer, the combination of a handle provided with an air-passage, a cylinder provided with air-passages, a valve provided with air-ports in said cylinder, a piston in said cylinder, a tool mounted at one end of said cylinder, a valve controlling the air-passage in said handle, and means for normally holding said valve positively locked.

20. In a pneumatic hammer, the combination of a handle provided with an air-passage, a cylinder, a valve and piston therein, a tool at one end of said cylinder, a valve for normally closing the air-passage in said handle, means for positively locking said valve in its closed position, and means operable by the workman for releasing and opening said valve.

21. In a pneumatic hammer, the combination of a handle provided with an air-passage, a cylinder provided with air-passages secured to said handle, a valve provided with air-ports located in said cylinder, a piston in said cylinder, a valve for normally closing the valve-passage in said handle, means for normally holding said valve locked in its closed position, and a pivoted lever for operating said valve.

22. In a pneumatic hammer, the combination of a handle provided with an air-passage, a cylinder provided with air-passages secured to said handle, a nut securing said cylinder and said handle together, a valve provided with air-ports located in said cylinder, a piston in said cylinder, a valve normally closing the air-passage in said handle, means for positively locking said valve in its closed position and means operable by the workman for opening said valve.

23. In a pneumatic hammer, the combination of a cylinder provided with air-passages, a piston in said cylinder, a tool, and a valve for regulating the action of the motor fluid, said cylinder being provided near the front end with an exit opening or port, whereby the pressure behind the piston is considerably diminished just before said piston strikes said tool.

24. In a pneumatic hammer, the combination of a cylinder provided with a screw-threaded head and with air-passages, a piston in said cylinder, a handle screwed upon said cylinder, a tool, and a valve for regulating the action of a motor fluid, said cylinder being provided near the front end with an exit opening or port, whereby the pressure behind the piston is considerably diminished just before it strikes said tool.

25. In a pneumatic hammer, the combination of a handle secured to said cylinder, said handle being provided with an inlet air-passage, a sliding stepped valve and a piston in said cylinder, a valve for controlling the passage of the air in the air-passage in said handle, means for normally holding said valve locked, and means for unlocking and opening said valve.

26. In a pneumatic hammer, the combination of a cylinder having a bore enlarged at each end, a tool in one end of said cylinder and a valve in the other end of said cylinder, said cylinder and valve being provided with air-passages, a piston in said cylinder, a handle provided with an air-passage, a valve for opening and closing the air-passage in said handle, and means for securing said handle and cylinder together.

27. In a pneumatic hammer, the combination of a cylinder provided with a bore enlarged at both ends with air-passages and an exit-opening near one end, a tool located in one end of said cylinder, a cylindrical valve provided with air-ports and located in the other end of said cylinder, a piston in said cylinder, and means for admitting air to said cylinder, and for cutting it off as desired.

28. In a pneumatic hammer, the combination of a cylinder having a bore enlarged at each end, a sleeve in one end of said cylinder and a cylindrical valve in the other end of said cylinder, said cylinder and valve being provided with air passages and ports, a piston in said cylinder, a tool in said sleeve, a handle provided with an air-passage, and a valve for normally closing the air-passage in said handle.

29. In a pneumatic hammer, the combination of a cylinder having an enlargement at each end, a tool in one end of said cylinder, a sliding cylindrical valve provided with air ports and passages located in the other end of said cylinder, said cylinder being provided with air-ports and vent-openings and one of said passages being nearly the whole length of said cylinder, a handle secured upon said cylinder and provided with an air-passage, a valve for governing said air-passage, means for normally holding said valve locked, and means for unlocking and opening said valve.

30. In a pneumatic hammer, the combination of a cylinder provided with an enlarged screw-threaded end, a screw-threaded handle engaging said end, a circular nut screwed into said handle and serving to aid in holding said handle and cylinder together, a washer provided with a projecting portion of the same size as the main bore of the piston, said cylinder being provided with a bore enlarged at each end, and a sliding cylindrical valve located in the enlargement at one end of said cylinder, part of said valve surrounding the extension of said washer.

31. In a pneumatic hammer, the combination of a handle provided with an air-passage, a cylinder provided with air-passages secured thereto, a circular nut surrounding said cylinder and screwed into said handle, said cylinder having a bore enlarged at each end, a stepped cylindrical valve provided with air ports and passages located in one end of said cylinder, and a piston in said cylinder.

32. In a pneumatic hammer, the combination of a cylinder provided with a sleeve at one end, a tool in said sleeve, a piston in said cylinder, a valve in one end of said cylinder, said cylinder-valve being provided with air ports and passages, a handle secured to said cylinder and provided with an air-passage, a valve for controlling said air-passage, means for normally holding said valve locked, and means for unlocking and opening said valve.

33. In a pneumatic hammer, the combination with a cylinder and a tool, a piston and a valve in said cylinder, of a handle provided with an air-passage secured to said cylinder, a perforated cylindrical screw-threaded plug passing through said air-passage, a valve working in said plug, means for normally holding said valve locked, means for unlocking said valve, and a pivoted lever for moving said valve after it has been unlocked.

34. In a pneumatic hammer, the combination of a cylinder, a tool, a piston and a valve in said cylinder with a handle secured to said cylinder and provided with an air-passage, a perforated cylindrical screw-threaded plug passing through said air-passage, a valve adapted to reciprocate in said plug, a spring in said plug engaging one end of said valve, said valve being provided with a cut-away portion, means engaging said cut-away portion for normally holding said valve locked, means for unlocking said valve, and a lever pivoted in said handle for operating said valve.

35. In a pneumatic hammer, the combination with a cylinder and a tool, a piston and a valve located in said cylinder, of a handle provided with an air-passage secured to said cylinder, said handle being also provided with a valve-passage and a plunger-passage, a perforated cylindrical screw-plug crossing the air-passage in said handle, a valve provided with a cut-away portion adapted to reciprocate in said valve-passage and plug, a plunger adapted to engage said cut-away portion to normally lock said valve, a stem and finger-piece secured to said plunger, and a pivoted lever for operating said valve.

36. In a pneumatic hammer, the combination of a cylinder and a tool, a piston and a valve located in said cylinder with a handle secured to said cylinder and provided with an air-passage, a valve-passage and a plunger-passage, a perforated cylindrical screw-plug crossing said air-passage, a spring in said plug, a valve provided with a cut-away portion adapted to reciprocate in said valve-passage and plug, a plunger adapted to engage the cut-away portion in said valve, a spring acting to force said plunger into said cut-away portion, a finger-piece and stem connected to said plunger, and a lever pivoted in said handle and engaging one end of said valve.

37. In a pneumatic hammer, the combination of a cylinder provided with air-passages and with a bore having enlargements at each end, a tool located in one of said enlargements, a piston located in said cylinder and a sliding cylindrical valve provided with air-ports located in the other end of said cylinder, a handle screwed upon said cylinder, a nut for securing said handle and said cylinder together, said handle being provided with an air-passage, a valve-passage, a plunger-passage and a slot, a cylindrical perforated screw-threaded plug crossing said air-passage, a valve provided with a cut-away portion adapted to be reciprocated in said plug and said valve-passage, a spring engaging one end of said plug, a plunger operating in said plunger-passage, a finger-piece and stem connected to said plunger, a spring engaging one end of said plunger, and an operating-lever pivoted in said slot.

38. In a pneumatic hammer, the combination of a cylinder, a tool, piston and valve in said cylinder with a handle secured to said cylinder, a circular nut surrounding said cylinder and screwed into said handle, means for preventing the rotation of said nut the handle being provided with an air-passage, a valve-passage, a plunger-passage and a slot, a perforated cylindrical screw-threaded plug crossing said air-passage, a spring in said plug, a valve provided with a cut-away portion, a spring-operated plunger adapted to engage the cut-away portion in said valve, and a lever pivoted in said slot and engaging one end of said valve.

39. In a pneumatic hammer, the combination of a cylinder having a bore enlarged at each end, a tool in one end of said cylinder and a sliding cylindrical valve in the other end of said cylinder, a piston in said cylinder, said valve and cylinder being provided with air ports and passages and said cylinder having an enlarged screw-threaded end with a handle screwed upon said cylinder, a nut surrounding said cylinder and screwed into said handle, said nut having teeth at one end, a toothed dog engaging said teeth, said handle being provided with an air-passage, a valve-passage, a plunger-passage and a slot, a perforated cylindrical screw-threaded plug in said air-passage, a spring in said plug, a valve having a cut-away portion, a spring-operated plunger for engaging the cut-away portion of said valve, a stem and finger-piece secured to said plunger, and a lever pivoted in the slot in said handle.

40. In a pneumatic hammer, the combination of a cylinder having a bore enlarged at each end, a tool in one end of said cylinder and a cylindrical valve in the other end of said cylinder, a piston in said cylinder, said cylinder and valve being provided with air ports and passages, and said cylinder being provided with enlarged screw-threaded ends with a handle screwed to said cylinder, a circular nut having teeth at one end screwed into said handle, a toothed dog located in the slot in said cylinder, and a spring adapted to force said dog into engagement with the teeth on said nut, said handle being provided with an air-passage.

41. In a pneumatic hammer, the combination of a cylinder, a piston, a valve, a handle screwed upon said cylinder, a nut screwed into said handle, said nut being provided with teeth at one end, a dog provided with teeth and with pins located in a slot in said cylinder, a spring engaging said dog, said handle being provided with an air-passage, a valve-passage, a plunger-passage and a slot, a screw-threaded perforated plug crossing said air-passage, a spring in said plug, a valve provided with a cut-away portion, a plunger adapted to engage said portion, a spring engaging one end of said plunger, a finger-piece and stem attached to said plunger, and a lever pivoted in the slot in said handle.

42. In a pneumatic hammer, the combination of a cylinder having an enlargement on each end, a tool in one end of said cylinder, a stepped cylindrical valve in the other end of said cylinder, a piston in said cylinder, said cylinder and valve being provided with air ports and passages, and said cylinder being provided with an enlarged screw-threaded end, a handle screwed upon said cylinder, a circular nut screwed into said handle and provided with teeth at one end, a dog provided with teeth and pins located in a slot in said cylinder, and a spring engaging said dog, said handle being provided with an air-passage.

43. In a pneumatic hammer, the combination of a cylinder provided

with an internal bore having enlargements at each end, a tool in one end of said cylinder, a sliding cylindrical valve in the other end of said cylinder, a piston in said cylinder, said cylinder and valve being provided with air ports and passages, and a handle secured to said cylinder, said handle being provided with an air-passage.

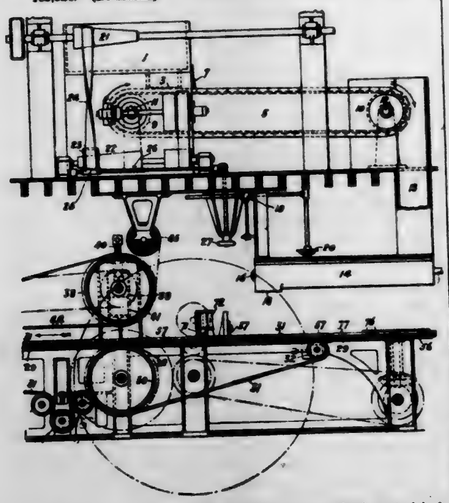
44. In a pneumatic hammer, the combination of a cylinder open at both ends and having a bore enlarged at each end, a tool in one end of said cylinder, a sliding cylindrical valve in the other end of said cylinder, a piston in said cylinder, a washer closing one end of said cylinder, a handle encircling said washer at one end of said cylinder, a nut screwed into said handle, means for preventing the rotation of said nut, said handle being provided with an air-passage, a valve-passage, a plunger-passage and a slot, a perforated cylindrical screw-threaded plug located in said air-passage, a spring in said plug, a valve having a cut-away portion, a spring-operated plunger adapted to engage said cut-away portion, a finger-piece and stem secured to said plunger, and a valve pivoted in said slot.

45. In a pneumatic hammer, the combination of a cylinder open at each end and provided with an internal bore enlarged at each end, a tool in one end of said cylinder, a sliding cylindrical valve in the other end of said cylinder, a piston in said cylinder, a washer closing one end of said cylinder, a handle secured to said cylinder, a nut screwed into said handle, and means for preventing the rotation of said nut, said handle being provided with an air passage.

46. In a pneumatic hammer, the combination of a cylinder open at each end and provided with a cylindrical bore enlarged at each end, a tool in one end of said cylinder, a sliding cylindrical valve in the other end of said cylinder, said valve and cylinder being provided with air ports and passages, and said cylinder being provided with an enlarged screw-threaded head, of a perforated washer closing one end of said cylinder, a handle screwed over said washer upon the enlarged end of said cylinder, a nut screwed into said handle, and means for preventing the rotation of said nut, said handle being provided with an air-passage.

47. In a pneumatic hammer, the combination of a cylinder open at both ends and having a central bore enlarged at both ends, a shell in one end of said cylinder, a sliding cylindrical valve in the other end of said cylinder, a passage in said cylinder, said cylinder and valve being provided with air passages and ports and said cylinder being also provided with an enlarged screw-threaded end, a handle screwed upon said cylinder, a nut screwed into said handle and having teeth at one end, a toothed dog engaging said nut, a spring engaging said dog, a perforated washer between said handle and said cylinder, said handle being provided with an air-passage, and a valve.

707,921. MACHINERY FOR MAKING SLABS WITH PLAIN OR ORNAMENTAL SURFACES OF PLASTIC CEMENT OR COMPOSITION. GEORGE B. HALL, London, England. Filed Apr. 30, 1902. Serial No. 105,526. (No model.)

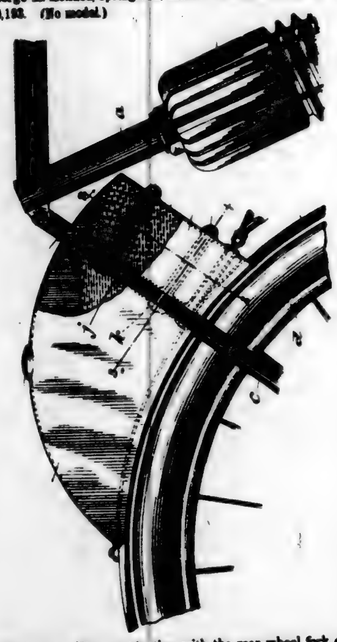


Claim.—1. A machine for the production from plastic material of a continuous sheet or slab adapted to be divided into predetermined lengths, comprising a flat table, an endless traveling band for receiving the plastic material, means for causing said band to travel continuously over the table, side fences for determining the width of the sheet or slab, a striker for spreading the plastic material upon the band, and a vertically-adjustable screeding-bar mounted to reciprocate in the direction of its own length over the surface of the sheet or slab transversely of the direction of the travel thereof so as to consolidate and level the plastic material to the required thickness, as described.

2. A machine for the continuous production from plastic material of separate slabs, comprising an endless band, a succession of molds for the slabs constituted as to the bottom of each mold by said endless band, as to the sides of the molds by a pair of endless chains of blocks traveling as one with the band, and as to the ends of said molds by cross-division bars engaging with said chains and serving to separate adjacent molds of the series, combined with means for spreading, consolidating and gaging the plastic material fed into the molds, substantially as described.

3. A machine for the continuous production from plastic material of separate slabs, comprising an endless band, cross-division bars extending at intervals across the band, the endless side chains traveling over sprocket-wheels rotating in vertical planes and provided with ribs for molding frogs in the edges of the slabs; said bands, side chains and division-bars cooperating to form a series of molds; and means for causing the side chains to diverge so as to effect the disengagement of said chains from the cross-division bars and of the frog-molding ribs on the chains, from the slabs, substantially as described.

707,922. FUEL OR OTHER RESERVOIR FOR INTERNAL-COMBUSTION ENGINES. CARL O. HEDSTROM, Portland, Conn., assignor to George M. Hendee, Springfield, Mass. Filed Oct. 28, 1901. Serial No. 80,163. (No model.)

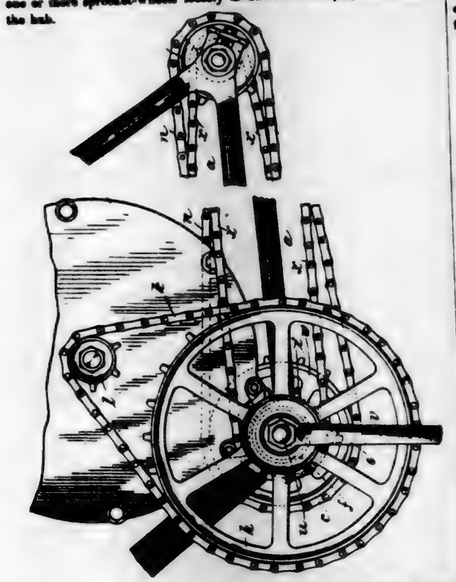


Claim.—1. The combination with the rear-wheel fork of a motor-cycle, of a reservoir located on each side of said fork, longitudinally of the machine, and means for securing said reservoirs one to the other, and whereby they may be securely clamped to the said fork, both of said reservoirs having an outlet one side of the vertical center of the rear wheel, the outlet of one reservoir passing through the other reservoir.

2. The combination with the rear-wheel fork of a motor-cycle, of a reservoir located on each side of said fork, longitudinally of the machine, tubular passages extending through one of said reservoirs, an outlet-pipe connected with the other reservoir extending through one of said passages, and a screw extending through another of said passages for securing said reservoirs together, and to said fork.

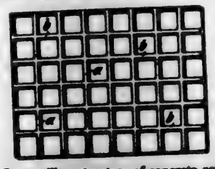
707,923. CHAIR-ADJUSTING DEVICE FOR MOTOR-VEHICLES. CARL O. HEDSTROM, Portland, Conn., assignor to George M. Hendee, Springfield, Mass. Filed Oct. 28, 1901. Serial No. 80,165. (No model.)

Claim.—1. In combination with the crank-hanger of a motor-cycle, a hub eccentrically supported thereon one end of which projects beyond the end of said hanger, and means for rotatably adjusting said hub; and one or more sprocket-wheels loosely mounted on said projecting end of the hub.



2. In combination with the crank-hanger of a motor-cycle, of a hub eccentrically supported therein, one end of which projects beyond the end of said hanger, and means for rotatably adjusting said hub; a driving and a driven sprocket-wheel secured on the same hub mounted on said projecting end of said eccentric hub and freely rotatable thereon, to which chains run both horizontally and vertically, whereby the rotatable adjustment of said eccentric hub may effect the adjustment of one of said chains without affecting the adjustment of the other.

707,924. CEILING STRUCTURE COMPOSED OF BETON AND IRON. FRANÇOIS HENNEBIQUE, Paris, France. Filed May 22, 1902. Serial No. 108,574. (No model.)

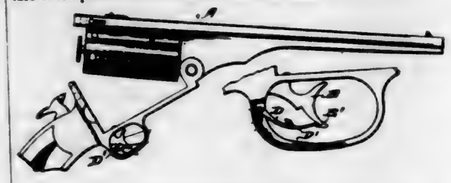


Claim.—1. In a ceiling structure of concrete and metal the combination of a series of concrete beams with another series of concrete beams lying crosswise to and in one plane with the first, and metal rods extending through both series of beams from the points of support through the tensile zones of the beams, and another set of metal rods from the points of support through the zones of compression and dipping at their middle points into the tensile zones of the beams, both sets of metal rods being embedded in the concrete beams.

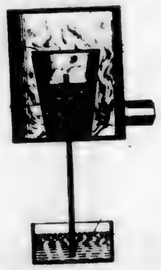
2. In ceiling structures a series of concrete beams and with another series of concrete beams crossing the first in combination with metal rods embedded in the beams and extending from the points of support through the tensile zones of the beams, another set of metal rods similarly embedded and extending from the zone of compression at the points of support to the tensile zone at their middle portion and metal stirrups also embedded in the beams and embracing both rods in each beam and extending up into the zone of compression.

707,925. SAFETY ATTACHMENT FOR FIREARMS. JESSE F. HERRON, Sebastian, Fla., assignor of one-half to Frank R. Hunter, Sebastian, Fla. Filed Sept. 28, 1901. Serial No. 76,207. (No model.)

Claim.—In a safety device for firearms, the combination with a trigger having a shoulder formed on its lower end, of a catch pivoted to the guard in the rear of the trigger and adapted to engage said shoulder, said catch having its pivoted end squared, and a spring secured at its lower end to the guard, its free end being adapted to bear against the squared face of the pivoted end of the catch when the catch is thrown up.



707,926. PROCESS OF EXTRACTING PRECIOUS METALS. WILMER HILT, Colon, Cal., and CLARENCE H. LAKE, Ashland, Oreg. Filed Mar. 20, 1902. Serial No. 99,036. (No specimens.)

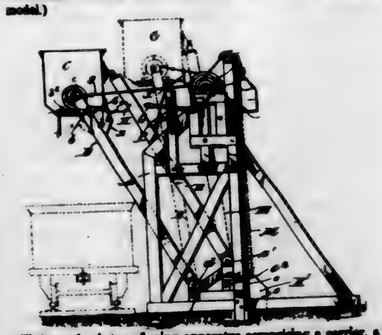


Claim.—1. The process herein described, of extracting precious metals from solutions thereof, which consists in producing zinc-vapor and conducting the same beneath the surface of said solutions, where it immediately replaces said precious metals, thereby precipitating the same.

2. The process herein described, of extracting precious metals from solutions thereof, which consists in producing cyanid solutions of said metals, vaporizing metallic zinc by means of heat, and conducting the vapor thus formed to a point beneath the surfaces of said solutions, thus producing finely-divided zinc which replaces the precious metals and thereby causes their precipitation.

3. The process herein described, of extracting precious metals from solutions thereof, which consists in producing zinc-vapor and condensing the same beneath the surfaces of said solutions, thereby causing the zinc to replace said precious metals in said solutions.

707,927. LOADING DEVICE FOR LOCOMOTIVES. GEORGE HOFFMAN, Fontanet, Ind. Filed May 1, 1902. Serial No. 105,512. (No model.)



Claim.—1. A transferring apparatus comprising a carrier, a tilting frame supporting the carrier at its upper end, a conical compensating drum and a cable connecting the carrier mechanism to the said drum and resting on the smaller circumferences of the cone when the frame is extended as described.

2. A transferring apparatus comprising a carrier, a tilting frame supporting the carrier at its upper end, a conical compensating drum, a cable

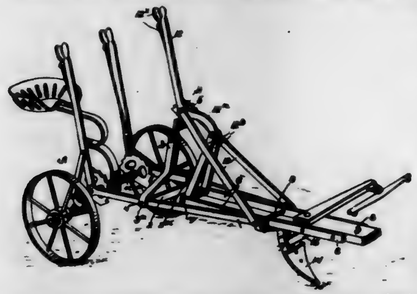
connecting the carrier mechanism to the said drum and resting on the smaller circumference of the cone when the frame is extended, a second conical drum rigidly connected to the first-named drum, and a weight and cable passing around said second conical drum and resting on the larger circumference of the drum when the frame is extended substantially as described.

3. A transferring apparatus comprising a carrier, a tilting frame supporting the carrier at its upper end, a horizontal shaft bearing a pair of conical compensating drums with spiral grooves, cables connecting the same to the carrier mechanism, and another conical compensating drum with cable wound reversely to the first-named and having attached thereto a balance-weight substantially as and for the purpose described.

4. The combination with the carrier and its tilting frame; of grooved and conical compensating drum with cable and weight, and a strap-brake embracing and lying inside the groove in said drum substantially as and for the purpose described.

5. The combination with the carrier and its parallel-motion supporting-frame; of spring-hinged trap-doors for the carrier having extended lugs at the ends, a bevel-faced hook-bolt, a rock-shaft with weighted crank-arm, and a rod connecting the crank-arm to its hook-bolt substantially as shown and described.

707,928. ATTACHMENT FOR PLANTERS. MAJOR JOHNSON, Coleman, Tex. Filed June 14, 1902. Serial No. 111,719. (No model.)



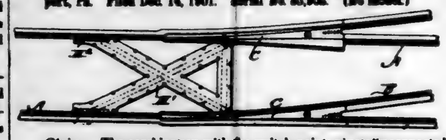
Claim.—1. An attachment for plows, comprising a frame having its rear end arranged to pivotally join with the cross-axle of a planter carriage or truck, a supplemental frame having its front end arranged to join with a draft-tongue, the two frames being pivotally joined to swing in independent vertical planes, a lever mechanism mounted on the main frame, and connected with the supplemental frame at a point to the rear of its connection with the main frame, and a sweep-carrying stock mounted on the outer end of the main frame, as specified.

2. The combination with the main frame, adapted to connect with the cross-axle of a planter-truck, to swing in a vertical plane; of a supplemental frame adapted to connect with the rear end of the draft-tongue and pivoted in the forward end of the main frame to swing in a vertical plane, a sweep-carrying stock hung on the fulcrum member that connects the two frames, said stock including a brace member adapted to fasten to the draft-tongue, a lever mechanism mounted on the main frame, and connections joining the said lever mechanism with the rear end of the supplemental frame, for the purposes described.

3. In an attachment for planters of the character described, the combination with the main frame, consisting of a pair of rearwardly-diverging bars, a bracket extended vertically from the rear part of said frame, a vertically-disposed rack member fixedly held on the upper end of the said bracket, and a lever fulcrumed on the said rack to swing in a longitudinal plane, said lever having a pawl to engage the rack and provided with a forwardly and downwardly curved extension; of the supplemental frame pivotally connected with the front end of the main frame to swing in a vertical plane between the sides of the said main frame, the front end of the supplemental frame being arranged to receive and secure the rear end of the draft-tongue, a pivoted link joining the lower curved end of the lever, and the rear end of the supplemental frame; and a plow-carrying stock mounted on the forward end of the main frame, all being arranged substantially as shown and for the purposes described.

4. The combination with the main frame, consisting of the diverging bars apertured at their outer ends, the bracket member extended vertically from the rear end of the main frame and secured to the side bars thereof, the upper end of said bracket carrying a segmental rack, and the fulcrum-pin *B* mounted in the front ends of the main frame; of the supplemental frame comprising two parallel bars mounted on the fulcrum-pin *B* to swing in a vertical plane between the side bars of the main frame, the front end of the said supplemental frame being extended and arranged to connect with the rear end of the draft-tongue, a sweep-stock hung on the aforesaid fulcrum member, said sweep-stock having a forwardly-extended brace to connect with the rear end of the draft-tongue, the link-arm members pivotally connected at their ends to the segmental rack and to the fulcrum member in the front end of the main frame, the lever 12 fulcrumed on the rack, said lever having a forwardly and downwardly curved extension 13ª, and pivotal links joining the said extension with the rear end of the supplemental frame, all being arranged substantially as shown and described.

707,929. SWITCH-OPERATING DEVICE. FRANK S. JOHN, Expert, Pa. Filed Dec. 14, 1901. Serial No. 85,902. (No model.)



Claim.—The combination with the switch-points pivotally connected by a cross-bar, of operating-rods pivotally secured to the cross-bar, and crossing each other, said rods bent away from each other at the point of crossing, the free ends of the rods provided with upwardly-projecting portions, said portions resting against the inner faces of the rails, means for contacting the upwardly-projecting portions, whereby the points are shifted, and a protecting-casing arranged about the cross-bars and the operating-rods.

707,930. PACKING-RING. HERMANN KIRCHHEIM, Berlin, Germany. Filed Mar. 7, 1902. Serial No. 97,094. (No model.)

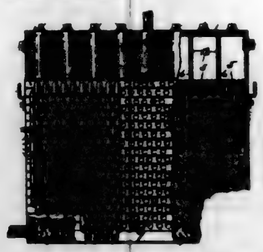
Claim.—1. The combination, substantially as and for the purpose set forth, of a packing-ring cut or stamped from asbestos or ordinary paste board or other suitable material, and flat strips of copper, zinc or other suitable metal to be inserted edgewise in this ring, the width of the strip being in the direction of the axis of the ring.

2. The combination, substantially as and for the purpose set forth, of a packing-ring cut or stamped from asbestos or ordinary paste board or other suitable material, and edgewise-inserted strips of copper, zinc or other material, this insertion extending throughout the entire thickness of the ring and all parts of the opposite edges being parallel with the opposite surfaces of the ring.

3. The combination, substantially as and for the purpose set forth, of a packing-ring cut or stamped from asbestos or ordinary paste board or other suitable material, and flat edgewise-inserted strips having corrugations.

4. The combination substantially as and for the purpose set forth, of a packing-ring provided with holes for the passage of flange-bolts, and edgewise-inserted strip, the central opening of the ring and also the bolt-holes being surrounded by the strip.

707,931. STEAM-GENERATOR. WILLARD A. KITTS, Sr., and WILLARD A. KITTS, Jr., Oswego, N. Y., assignors to Kitts Semi-Flash Boiler Company, Oswego, N. Y., a Corporation. Filed Mar. 22, 1902. Serial No. 99,433. (No model.)



Claim.—1. A steam-generator comprising a water-containing shell having a series of upright water-containing compartments, and a plurality of tubes projecting laterally and downwardly from opposite faces of the shell and having their inner ends communicating with the compartments and their outer ends closed.

2. A steam-generator comprising a water-containing shell having inlet and outlet passages and provided with a series of upright transverse partitions dividing the shell into a series of compartments, each partition

having a passage connecting adjacent compartments and a series of tubes projecting from the opposite walls of the compartments and communicating therewith, the outer ends of the tubes being closed.

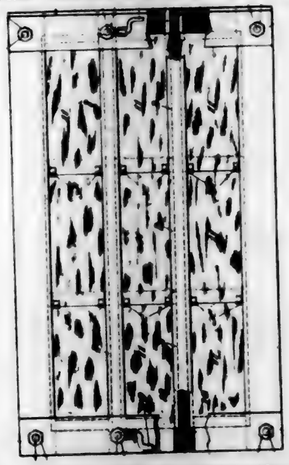
3. A steam-generator comprising a water-containing shell having inlet and outlet passages and provided with a series of upright transverse partitions dividing the shell into a series of compartments, each partition having a passage connecting adjacent compartments and a series of tubes projecting from the opposite walls of the shell and having their inner ends almost with said partitions and communicating with adjacent compartments and their outer ends closed.

4. A steam-generator comprising a water-containing shell having inlet and outlet passages and divided into a series of substantially parallel upright compartments, said shell having restricted passages connecting the compartments and a plurality of tubes projecting outwardly and downwardly from the opposite side walls of the shell and having their inner ends communicating with the compartments and their outer ends closed.

5. A steam-generator comprising an upright shell of less transverse width than length and provided with a series of upright water-compartments arranged side by side and communicating with each other, one of the end walls of each compartment being provided with an opening and a closure for said opening, and a series of water-tubes projecting laterally and downwardly from the opposite side walls of the shell and having their inner ends communicating with the compartments and their outer ends closed.

6. A steam-generator comprising an upright elongated shell having a series of substantially parallel upright water-compartments arranged side by side in the direction of greatest length of the shell, and a series of laterally-projecting water-tubes arranged in staggered relation with each other and having their corresponding ends communicating with the compartments and their outer ends closed.

707,932. FORCING-FRAME OR LIKE SASH OR WINDOW. GUSTAV KNOCHENHAUER, Schenia, near Rudolstadt, Germany. Filed Aug. 11, 1902. Serial No. 119,476. (No model.)

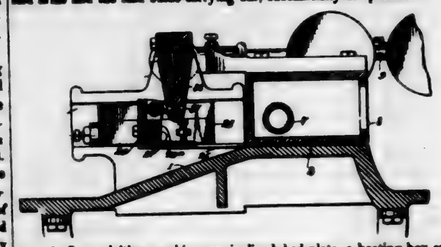


Claim.—1. A forcing or like sash or window with readily-removable parts comprising wooden longitudinal side bars wooden longitudinal intermediate bars connected together at their upper and lower ends by easily-removable metal bars and screw-bolts the bars being provided with longitudinal grooves adapted to receive the glass plates and with water-discharge passages immediately beneath the grooves the spaces between the longitudinal bars being filled up by wooden blocks forming together with the metal cross-bars the cross-bars of the frame substantially as described.

2. A forcing or like sash consisting of longitudinally-extending side bars, longitudinally-extending intermediate bars, said bars provided with grooves adapted to receive glass plates and further provided with water-discharge passages, cross-bars connecting said longitudinally-extending bars together, and closure-blocks supported by the cross-bars and arranged between the longitudinally-extending bars.

707,933. PLANTING-MACHINE. HILLARY F. KOOB, New York N. Y. Filed Apr. 17, 1902. Serial No. 103,243. (No model.)

Claim.—1. In a planting-machine, an inclined bed, a hooding and pressing box, a rock-shaft, means for imparting motion to the rock-shaft, carrier-blocks mounted to slide on a horizontal plane in the machine-frame above the bed-plate, a blade-carrying bar mounted to swing in said carrier-blocks, a plate consisting of a plurality of sections attached to said bar, arms depending from the rock-shaft, and link connections between said arms and the said blade-carrying bar, substantially as specified.

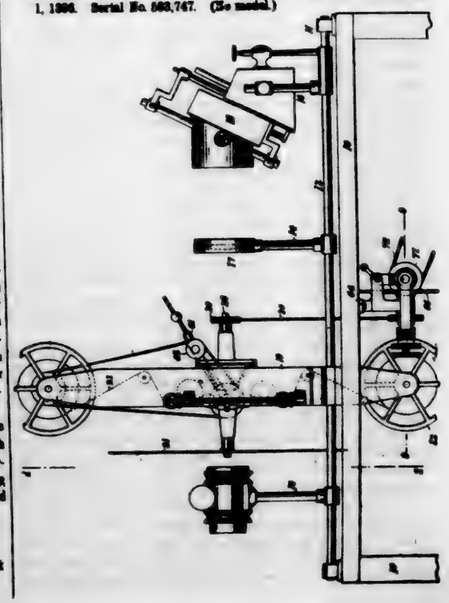


2. In a planting-machine, an inclined bed-plate, a hooding-box arranged to swing above the machine, carrier-blocks mounted to slide above the bed-plate, a blade-carrying bar having swinging connection with said carriers, a planting-blade attached to said bar, a rock-shaft, arms depending from said rock-shaft, link connections between the arms and said bar, and means for imparting motion to the rock-shaft, substantially as specified.

3. A planting-machine comprising an inclined bed-plate, carrier-blocks mounted to slide above said bed-plate, guides in which the blocks are movable, yielding walls for said carrier-blocks for engaging with walls of the guideways, a blade-carrying bar having swinging connection with said carrier-blocks, a rock-shaft, arms depending from said rock-shaft, link connections between the arms and said bar, and means for rocking the rock-shaft, substantially as specified.

4. A planting-machine comprising a bed-plate, a weighted hooding-box mounted to swing over the bed-plate, carrier-blocks mounted to slide over the bed-plate, a blade-carrying bar having swinging connection with said carrier-blocks, a blade secured to the bar, a rock-shaft arranged above the bar, arms depending from said rock-shaft, link connections between said arms and said bar, a driving or power shaft, an adjustable wrist-pin carried by said driving or power shaft, a crank on the rock-shaft, and a pitman connection between said wrist-pin and said crank-arm, substantially as specified.

707,934. PROJECTING-KINETOSCOPE. WOODVILLE LATHAM, New York, N. Y., assignor, by mesne assignments, to E. & H. T. Anthony & Co., New York, N. Y., a Corporation of New York. Filed June 1, 1896. Serial No. 593,747. (No model.)



Claim.—1. The combination with devices for supporting the bulk of a flexible film before and after exposure, of feeding mechanisms located between the devices for supporting the film and separate and distinct therefrom, one of said feeding mechanisms being constructed to uniformly feed the film and produce a predetermined supply of slack, and the other adapted to intermittently feed the slack across the exposure-window.

2. The combination with devices for supporting the bulk of the film before and after exposure, of feeding mechanisms located between the devices for supporting the film and separate and distinct therefrom, one of said feeding mechanisms being constructed to uniformly feed the film and produce a predetermined supply of slack, and the other adapted to intermittently feed the slack film across the exposure-window, and constructed also to cause the intervals of rest of the film to exceed its intervals of movement.

3. The combination with devices which support the bulk of the film and supply it for exposure and receive it after exposure, of positively-driven devices separate and distinct from the film-supporting devices, located between them and at opposite sides of the exposure-window, and which respectively engage with and accurately and uniformly feed the film, and which respectively produce and take up slack in it, and an intermittently-acting device located between said last-named devices which intermittently moves the slackened part of the film across the exposure-window.

4. The combination with devices which support the bulk of a flexible strip or film and supply it for exposure and receive it after exposure, of positively-driven devices separate and distinct from the film-supporting devices and which engage the film and accurately compel its movement, and which feed the film by uniform and continuous rotary action, and an intermittently-acting device located between said last-named devices and which moves the slackened part of the film picture by picture across the exposure-window and causes its period of rest to exceed its period of movement.

5. The combination with devices which support the bulk of a flexible film and supply it for exposure and receive it after exposure, of positively-driven devices separate and distinct from the film-supporting devices and located between them at opposite sides of the exposure-window, and which engage the film and accurately insure its feeding, which last-named devices respectively produce and take up slack in the film, and an intermittently-acting device provided with teeth which engage in holes in the film whereby it feeds the film across the exposure opening.

6. The combination with devices which support the bulk of a flexible film and supply it for exposure and receive it after exposure, of a positively-driven device entirely disconnected from the said film-supporting devices located between the film-supplying device and the exposure-window and which produces a loop of slack film, and an intermittently-acting device which engages with the film and feeds the slackened part of it across the exposure-window, and causes its period of rest to exceed its period of movement.

7. The combination with devices adapted to support the bulk of a flexible film and supply it for exposure and receive it after exposure, of positively-driven toothed rotary devices located between and entirely disconnected from said supporting devices and at opposite sides of the exposure-window, said toothed devices being adapted to carry and feed the flexible film by the engagement of their teeth with equally-spaced holes made in the edges of the film and to respectively produce and take up slack in the film, and an intermittently-acting rotary feeding device also provided with teeth which engage with the holes in the film, whereby the film is intermittently fed across the exposure-opening.

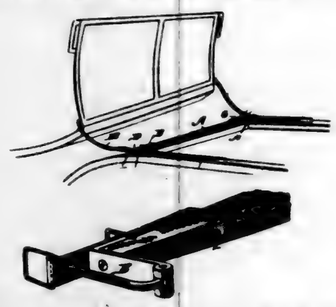
8. The combination with two reels which support the bulk of a flexible film, one of which supplies it for exposure and the other receives it after exposure, of a positively-driven device separate and distinct from the said reels and located between the supply-reel and the exposure-window and which produces a loop of slack film, and an intermittently-acting device likewise positively driven which moves the film picture by picture into the optical axis at the exposure-window and causes each picture to remain momentarily at rest in the optical axis.

9. The combination with two rotary reels which support the bulk of a flexible film, one of which supplies the film for exposure and the other coils it up after exposure, of two rotary feeding mechanisms located between said reels and separate and distinct from them, one constructed to feed the film intermittently and cause it to move picture by picture across the axis of the lens and to come to rest in said axis, the other constructed to feed the film continuously and uniformly and thus provide a constant supply of slack film and gearing positively connecting the said two feeding mechanisms for maintaining a fixed relation between them.

10. The combination with two rotary reels adapted to support the bulk of a flexible film, one of which supplies the film for exposure and the other receives it after exposure, of two toothed rotary feeding-rollers located between said film-supporting reels and separate and distinct therefrom and adapted to carry and feed the film by the engagement of their teeth with equally-spaced holes in the edges of the film, actuating mechanism and connecting-gearing between said feeding-rollers which positively actuates one of the feeding-rollers so as to feed the film intermittently and cause its interval of rest to exceed its interval of motion and which positively actuates also the other feeding-roller continuously and thus provides a constant supply of slack film.

11. The combination with the main shaft provided with a broken gear mounted in eccentric bearings and a feed-drum whose shaft is provided with a broken gear which meshes with the first-named broken gear, of means for adjusting said bearings to regulate the contact between said gears.

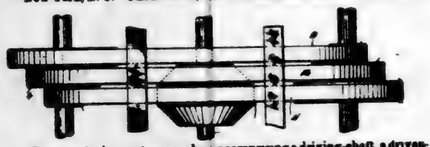
707,985. SINGLETREE ATTACHMENT. JOHN W. MAGARVY, Newburn, Tenn., assignor of one-half to L. G. Tidwell, Newburn, Tenn. Filed Feb. 13, 1902. Serial No. 93,894. (No model.)



Claim.—1. In a device of the character described, the combination with a singletree, having a pivoted rearwardly-curved hook member, a spring attached to the end of said singletree and adapted to engage said hook member, and means for releasing the hook member from such engagement.

2. In a device of the character described, the combination with a singletree, having an L-shaped plate attached to each end thereof, and a rearwardly-curved hook member pivoted to each plate, of flat rectangular springs attached to the rear portion of the singletree and extending beyond the ends of same, means for normally holding said hook members in engagement with said springs, and means for withdrawing the springs from such engagement.

707,986. VARIABLE-SPEED GEAR. HAMILTON F. HORTEROP, New York, N. Y. Filed June 3, 1902. Serial No. 110,077. (No model.)



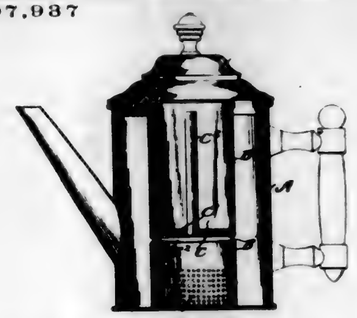
Claim.—1. A variable-speed gear comprising a driving-shaft, a driven-shaft, step-pulleys on the shafts arranged in reverse order, belts connecting opposite pulleys, a take-up pulley mounted to slide transversely of the first-named pulleys, the said take-up pulley having cam-shaped or tapered sides, and means for shifting said take-up pulley, substantially as specified.

2. A variable-speed gear comprising a driving-shaft, a driven shaft, step-pulleys arranged on said shafts in reverse order, band connections between opposite pulleys, means for preventing lateral movement of the bands on the pulleys, a shaft mounted to slide transversely of the pulleys, a take-up pulley mounted on said sliding shaft and having inclined sides, a lever for shifting said shaft, and fixed rods extending downward between adjacent belts, substantially as specified.

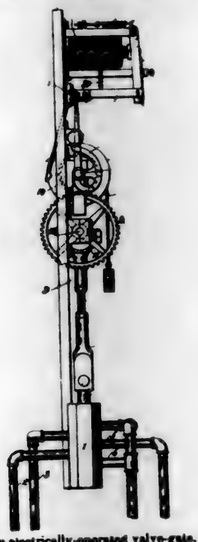
707,987. COFFEE-POT. HENRY HUTKINS, Henderson, N. C. Filed Jan. 20, 1902. Serial No. 90,503. (No model.)

Claim.—The combination with a coffee-pot, of a cylinder arranged therein resting upon the bottom and rigidly secured to said bottom, the lower portion of said cylinder being perforated, said cylinder having an inwardly-projecting annular bead at a point above the perforations, and a perforated follower adapted to rest upon said bead, said follower having a handle, the upper end of which is adapted to rest substantially even with the top of the cylinder, substantially as specified.

707,987



707,988. ELECTRICALLY-OPERATED VALVE-GATE. ALEXANDER ORR, Gloversville, N. Y. Filed Apr. 21, 1902. Serial No. 103,909. (No model.)



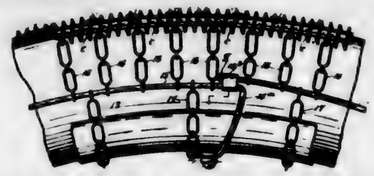
Claim.—1. An electrically-operated valve-gate, comprising a valve-stem for operating a valve, motor mechanism for actuating said valve-stem, said motor mechanism being provided with a revoluble arm, a lever provided with a boss for engaging said arm, thereby normally restraining said motor mechanism, and means controllable at will for actuating said lever, thus causing said boss to momentarily disengage said arm.

2. An electrically-operated valve-gate, comprising a valve-stem for operating a valve, motor mechanism for actuating said valve-stem, said motor mechanism being provided with a revolvable arm and with a cam, a lever provided with a boss for normally engaging said arm for the purpose of restraining said motor mechanism, and also provided with a surface to be engaged by said cam, and means controllable at will for releasing said lever.

3. An electrically-operated valve-gate, comprising a valve-stem for operating a valve, motor mechanism for actuating said valve-stem, said motor mechanism being provided with a revolvable arm and with a cam, a lever provided with a boss for normally engaging said arm, thus restraining said motor mechanism, and also provided with a surface to be engaged by said cam, an electromagnet, means for energizing the same, an armature for said magnet, and mechanism controllable by said armature for momentarily releasing said lever.

707,989. ARMOR FOR VEHICLE-TIRES. CHARLES H. PASCHEN, Buffalo, N. Y. Filed Feb. 26, 1902. Serial No. 96,713. (No model.)

Claim.—1. The combination with a wheel-rim, and a tire-ring, of an armor-ring mounted upon the periphery of the tire-ring and provided with notches in its edges, a wire coil-ring seated on the tire-ring and engaging the notches of the armor-ring, and means secured to the wheel-rim and engaging the coil-ring for securing the latter to the former.



2. The combination with a wheel-rim, and a tire-ring, of an armor-ring mounted upon the periphery of the tire-ring, a spring coil-ring held on each edge of the armor-ring and seated on the periphery of the tire-ring, one at each side of the center thereof and means secured to the wheel-rim and engaging the coil-rings for holding the latter in position on the former.

3. The combination with a wheel-rim, and a tire-ring thereon, of a plate-metal armor-ring seated upon the tire-ring and having perforations and notches at each edge thereof, coil-rings held in the perforations and notches of the armor-ring and engaging the periphery of the tire-ring, and means for securing the armor-ring to the wheel-rim.

4. The combination with a wheel-rim, an inflatable tire-ring seated upon the wheel-rim, an armor-ring on the tire-ring, and coil-rings held in perforations and notches at the sides of the armor-ring so as to seat upon the tire-ring, of tension-rings secured upon the wheel-rim and disposed at opposite sides of the tire-ring, flexible connections extended between the tension-rings and the coil-rings, and flexible connections extended from the tension-rings beneath the wheel-rim and secured thereto.

5. The combination with a wheel-rim, an inflatable tire-ring seated upon the wheel-rim, a plate-metal armor-ring mounted upon the tire-ring, two coil-rings held at the side edges of the armor-ring, and spaced tread-plates having their ends engaged with the coil-rings and seating upon the armor-ring, of two tension-rings disposed oppositely at the sides of the tire-ring, arms extended from the tension-rings beneath the wheel-rim, means for securing the ends of said arms upon the wheel-rim, pliable connections extended between the coil-rings and the tension-rings, and pliable connections extended from the wheel-rim to the tension-rings.

6. The combination with a wheel-rim, and a tire-ring, of tension-rings arranged on opposite sides of the tire-ring and each having an arm extending therefrom, said arms extending beneath the wheel-rim and secured thereto.

7. In a device of the character described, the tension-rings, arranged on opposite sides of the tire-ring, each tension-ring having its ends held together by a coupling-block, and each provided with a lateral arm which projects beneath and is secured to the wheel-rim.

8. In a device of the character described, a plate-metal armor-ring having perforations and notches in each edge, and a coil wire-ring on each edge of the armor-ring, the coils of the wire ring being passed through the perforations and seated in the notches of the armor-ring.

9. In a device of the character described, the wire coil-rings held interlocked with the side edges of the plate-metal armor-ring, and the spaced tread-plates having perforations in their ends which receive the coils of the wire coil-rings.

10. An armor for vehicle-tires, comprising an armor-ring, a coil-ring on each edge of the armor-ring, transverse tread-plates on the outer face of the armor-plate, and means for securing the armor-plates to the wheel-rim, as set forth.

11. An armor for vehicle-tires, comprising an armor-ring, tread-plates on the outer face of the armor-ring, a coil-ring on each edge of the armor-ring and securing the tread-plates to the armor-ring, oppositely-arranged tension-rings secured to the wheel-rim, and connections between the tension-rings and the coil-rings of the armor-ring, as set forth.

12. An armor for vehicle-tires, comprising an armor-ring, tread-plates on the outer face of the armor-ring, a coil-ring on each edge of the armor-ring and securing the tread-plates in position, oppositely-arranged tension-rings secured to the wheel-rim, flexible connections between the tension-rings and the coil-rings and flexible connections between the wheel-rim and tension-rings, as set forth.

13. In an armor for vehicle-tires, an armor-plate provided with notches in its edges and openings near said edges, coil-rings engaging the openings and notches of the armor-ring, and transversely-extending tread-plates on the armor-ring and having openings in their ends to receive the coils of the said rings, as set forth.

707,940. SASH-LOCK. BOBBIE A. PATTERSON, Dunbar, Nebr. Filed Apr. 3, 1902. Serial No. 101,250. (No model.)

Claim.—1. In a sash-lock, the combination of a casing having a slot

arranged thereon throughout its entire length, and notches arranged in the casing and communicating with the slot, of a spring-actuated sliding bolt held within the casing, an arm pivotally held to the said bolt and having its inner end provided with a finger portion that is adapted for engagement with the said notches, substantially as shown and for the purpose specified.

2. In a sash-lock, the combination of a casing having a slot arranged thereon and notches arranged upon either side of the slot and communicating therewith, lateral extensions arranged upon the casing, a bolt operating within the casing and having a shoulder or collar formed integral therewith, an enlargement formed upon one side of the collar that is adapted to protrude through the slot, a spring arranged upon the inner end of the said bolt and adapted to bear at one end against the casing and at its opposite end against the said shoulder or collar, an arm pivotally held upon the said enlargement and having its outer end terminating in an angular portion and its inner end terminating in an inwardly-bent finger portion, substantially as and for the purpose specified.

707,941. EAVES-TROUGH HANGER. HOWARD FOUT, Hollidaysburg, Pa. Filed Mar. 15, 1902. Serial No. 98,370. (Eq model.)

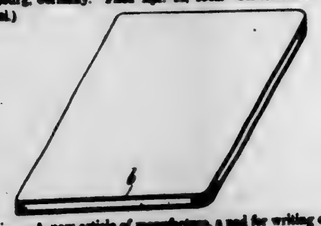
Claim.—1. A device of the kind described comprising the hanger member having a depending vertical slotted portion, the inner face of which is provided with notched ribs, and a bracket-arm having a T-shaped pin, and a perforated lug adapted to be passed through the said slotted member, and a pin adapted to be passed through the said perforated lug, and engage the notched ribs, substantially as specified.

2. The combination with the hanger member, the depending portion of which is slotted vertically and provided with notched ribs upon opposite sides of the said slot, of a bracket-arm having a T-shaped pin adjacent to its upper end and a perforated lug adjacent to its lower end, said lug being adapted to be passed through the vertical slot, and a locking-pin adapted to be passed through the perforated lug, for the purpose described.

3. The combination with a hanger member having its depending portion slotted vertically and provided with notched ribs upon opposite sides of the slot, the bracket member comprising the curved supporting-arm having the forwardly-projecting lip, and the plate having the T-shaped pin at its upper end, and a rearwardly-projecting perforated lug adjacent to its lower end, and the locking-pin adapted to be passed through the said perforated lug for the purpose specified.

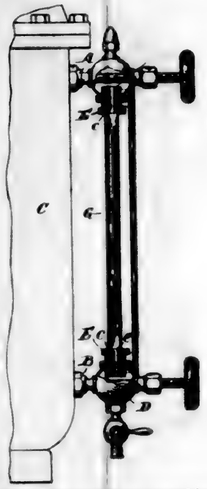
4. The combination with the plate having the tapering guides, of a hanger member having tapering wings adapted to fit said tapering guides, said member being slotted vertically and provided with notched ribs on opposite sides of the slot, and the bracket member having rearwardly-projecting T-shaped pin adjacent to its upper end, and a perforated lug adjacent to its lower end, and the locking-pin adapted to be passed through said perforated lug for the purpose specified.

707,942. WRITING OR COPYING PAD. FRIEDRICH G. J. PUST, Hamburg, Germany. Filed Apr. 12, 1902. Serial No. 102,643. (No model.)



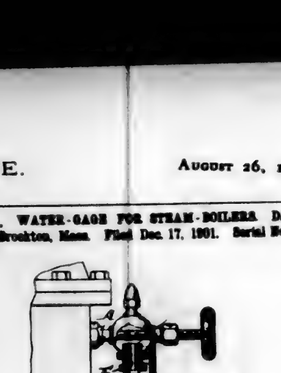
Claim.—A new article of manufacture, a pad for writing or copying purposes comprising a layer of soft felt having a sheet of oiled paper cemented to one or both its faces, as set forth.

707,948. WATER-GAGE FOR STEAM-BOILERS. DAVID W. ROCKWELL, Brockton, Mass. Filed Dec. 17, 1901. Serial No. 86,226. (No model.)



Claim.—A water-gage comprising upper and lower arms each provided with a valve, gage-tube sockets or couplings screwed into the valve-casings and provided with chambers closed at their inner ends, a gage-tube having its ends fitted within said chambers, inlet-nozzles projecting from the inner ends of said chambers and extending into the end portions of the gage-tube, packing-rings interposed between the ends of the gage-tube and the closed ends of the chambers, and check-nuts turning on the exterior threaded portions of the sockets and adapted to be screwed against the valve-casings.

707,944. TWO-SPEED DRIVING MECHANISM. FRANCIS I. SANDERS, Nottingham, England. Filed July 31, 1902. Serial No. 116,407. (No model.)

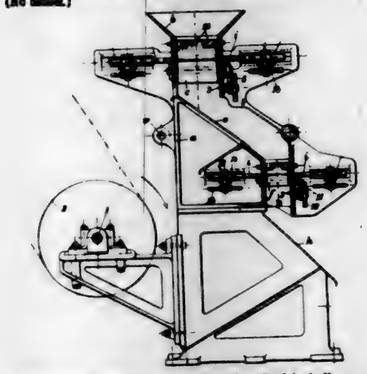


Claim.—1. The combination with a driving-axle and a crank fixed thereon, of a cylindrical journal-block grooved on one end to straddle the crank eccentrically to the axle and secured to the crank, a roller-clutch on the periphery of the journal-block, a collar rotatable on the axle, a ratchet-wheel and gear-wheel rigid on the collar, a sprocket-wheel rotatable on the collar and provided with an internal gear, an intermediate gear-wheel rotatably mounted on the journal-block and held against rotation thereon in one direction by said clutch, a pawl arranged to normally hold said ratchet-wheel against rotation, and means under the control of the operator for throwing and holding the pawl out of engagement with the ratchet-wheel, substantially as described.

2. The combination with a driving-axle and a crank fixed thereon, of a collar rotatable on the axle, a sprocket-wheel rotatable on the collar and provided with an internal gear, a ratchet-wheel and a gear-wheel fixed on the collar on opposite sides of the sprocket-wheel, an intermediate gear-wheel rotatably mounted on the crank eccentrically to the axle and gearing with said internal gear and the gear-wheel on the collar, means for preventing the rotation of the intermediate gear-wheel about its axis in one direction, and means under the control of the operator for holding the ratchet-wheel against rotation, substantially as described.

2. The combination with a driving-axle and a crank fixed thereon, of a collar rotatable on the axle, a sprocket-wheel rotatable on the collar and provided with an internal gear, a ratchet-wheel and a gear-wheel fixed on the collar on the opposite sides of the collar, said ratchet-wheel and gear-wheel being recessed on their adjacent faces for the reception of the hub of the sprocket-wheel to give a broad bearing to the latter, an intermediate gear rotatably mounted on the crank eccentrically to the axle and gearing with said internal gear and the gear-wheel on the collar, means for preventing rotation of the intermediate gear-wheel about its axis in one direction, and means under the control of the operator for holding the ratchet-wheel against rotation, substantially as described.

707,945. MACHINE FOR COAL-BREAKING. LÉON DE BOESTIER DE SAUVIGNY, Paris, France. Filed July 18, 1901. Serial No. 68,576. (No model.)



Claim.—1. A machine of the class described including a plurality of superposed jaws arranged in pairs, means for actuating said jaws, picks also arranged in pairs and adapted to coact with the respective pairs of jaws, means for actuating the picks and a sieve adapted to receive the crushed material from the upper jaws and serving to separate the fine material from the coarse and to direct the latter toward the lower jaws.

2. A machine of the class described including a plurality of superposed oscillatory jaws arranged in pairs and polygonal in cross-section, picks also arranged in pairs and adapted to coact with the respective pairs of jaws, means for actuating the picks, and a sieve adapted to receive the crushed material from the upper jaws and serving to separate the fine material from the coarse and to direct the latter to the lower jaws.

3. A machine of the class described including a plurality of superposed jaws arranged in pairs, means for actuating said jaws, picks also arranged in pairs and adapted to coact with the respective pairs of jaws, means for actuating the picks, a sieve adapted to receive the crushed material from the upper jaws and serving to separate the fine material from the coarse and to direct the latter toward the lower jaws, and means bridging the adjacent jaws of the respective pairs to prevent the passage of material therebetween.

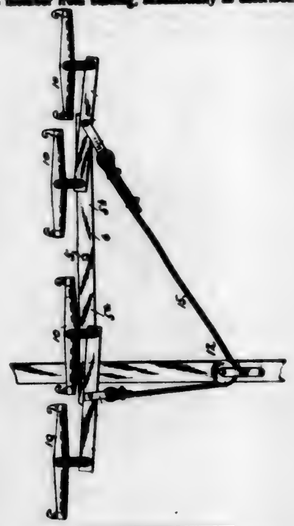
4. A machine of the class described including jaws arranged in pairs, picks arranged in pairs adapted to travel toward and from each other, and mechanism for coördinately reciprocating the picks and oscillating the jaws.

5. A machine of the class described including jaws arranged in pairs, picks arranged in pairs adapted to travel toward and from each other, mechanism for coördinately reciprocating the picks and oscillating the jaws, and means for bridging the jaws of the respective pairs to prevent the passage of material between the same.

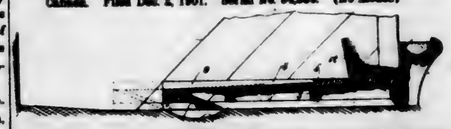
6. A machine of the class described including a plurality of superposed oscillatory jaws, picks also arranged in pairs to cooperate with the respective pairs of jaws, a sieve arranged to receive the crushed material from the upper jaws and serving to separate the fine material from the coarse and to direct the latter toward the lower jaws, and mechanism for oscillating the upper and lower jaws in opposite directions and for simultaneously reciprocating said picks in opposite directions.

707,946. FOUR-HORSE EVENER. JAMES W. SAYRE, Benson, Mo. Filed Sept. 14, 1901. Serial No. 75,304. (No model.)

Claim.—In an evener, the combination with the pole of a vehicle, of an arm pivotally secured to the upper face of said pole, a brace pivoted to the under face of said pole and to the free end of said arm, an evener-bar centrally pivoted to the free end of said arm, clevises secured by bolts to the outer ends of said evener-bar and not embracing the same, doubletrees pivoted on said bolts and embraced by said clevises, a sheave mounted on said pole, a flexible member passing around said sheave and attached at its ends to said clevises, said sheave being inclined to prevent said flexible member from binding, substantially as described.



707,947. ANIMAL-STALL. RICHARD SMITH, Fort William, Canada. Filed Dec. 2, 1901. Serial No. 84,339. (No model.)



Claim.—1. In a stall, a floor-section having channels in its upper surface, extending lengthwise of the stall, and openings in which the channels terminate, and an inclined deflector secured to the rear end of the floor-section and extending forwardly under said openings, substantially as specified.

2. A stall constructed to receive two animals and provided with two slidable floor-sections each having channels terminating in openings at their rear ends, the channels of one section extending nearly the length of the section, and the channels of the other extending about one-fourth the length of the same, and inclined deflectors secured to the sections under the said openings, as set forth.

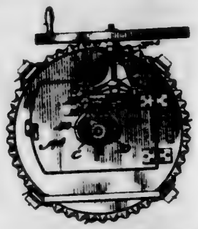
707,948. SHOVEL ATTACHMENT. WILLIAM T. SPILLANE, Red Lake Falls, Minn. Filed Mar. 26, 1902. Serial No. 100,094. (No model.)

Claim.—1. The combination with a fork, of a removable shovel attachment comprising a strip of sheet metal reboot under its lower end and

struck downwardly, reinforcing such end and forming a pocket receiving and inclosing the extremities of the fork, the downwardly-struck portions of the attachment providing a rear shoulder having a series of apertures receiving the extremities of the fork, and fastening means on the attachment to engage the upper part of the fork.

2. The combination with a fork, of a removable shovel attachment comprising a sheet-metal strip which is bowed longitudinally and has the lower end rabbeted under and struck downwardly for reinforcing such end and forming a pocket receiving and inclosing the forward extremities of the fork-tines, a clip in the center of the under side of the attachment through which the center fork-tine is inserted, and an upper yoke having bendable arms to engage the head of the fork.

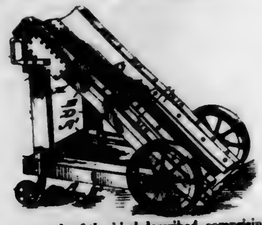
707,949. GEARING FOR WASHING-MACHINES. JASPER H. STANFIELD, Muskegon, Mich. Filed Mar. 22, 1902. Serial No. 99,479. (No model.)



Claim.—1. In a machine of the kind described, the combination with a base-plate, of a casting pivoted thereon, said casting having internal and external gear-teeth, a reciprocating rack-bar adapted to engage the external teeth, a pinion arranged for engagement with the internal teeth, and means for operating the reciprocating rack-bar, substantially as described.

2. The combination with a base-plate provided with a rib and guide-lug, of a casting pivoted thereon, said casting having interior and exterior gear-teeth, a pinion arranged for engagement with the interior gear-teeth, a reciprocating bar adapted to slide upon the rib formed upon the base-plate, and through the guide-lug connected to the said base-plate, said rack-bar and exterior gear-teeth intermeshing with each other, a drive-shaft mounted upon the base-plate, and having a crank-arm attached to its inner end, a roller pivotally connected to said crank-arm, a frame integral with the rack-bar and in which the roller operates, all arranged and adapted to operate substantially as described.

707,950. TRUCK. GEORGE H. STEER, Cincinnati, Ohio. Filed Mar. 3, 1902. Serial No. 96,534. (No model.)

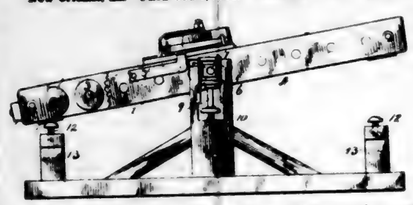


Claim.—1. A truck of the kind described, comprising the horizontal base or platform, the front wheels and drop-axle, caster-wheels for supporting the rear end, the upright standards arranged at the rear end of the frame or platform, the inclined side beams, and the plate connecting the said side beams, all of said parts being rigidly connected for the purpose specified.

2. A truck of the kind described, comprising the base or platform, the axle and wheels for supporting the forward end, the caster-wheel for supporting the rear end, the upright standards, the inclined side beams, the curved metallic plate connecting the said inclined side beams, and the roller arranged between the forward ends of said inclined side beams, and the handles attached to the upper ends of said side beams, substantially as specified.

3. A truck comprising a horizontal base or platform, the axle and wheels for supporting the forward end of said base or platform, the caster-wheels for supporting the rear end of the same, the upright standards, the inclined side beams, the curved metallic plate supported by the said side beams, the transverse and longitudinal brace-pieces, the metallic straps arranged upon the side pieces, the roller arranged at the forward end of the side beams and secured by means of the metallic straps, and the tapering straps arranged upon the curved metallic plate adjacent to its forward end, for the purpose described.

707,951. LOG OR FREIGHT DUMPING APPARATUS. TONY ALEXANDER, Bismarck, Miss., assignor of one-half to Gideon Alexander, New Orleans, La. Filed Oct. 7, 1901. Serial No. 77,781. (No model.)



Claim.—1. An apparatus for receiving and discharging logs or other freight, which comprises the fixed frame, having supports, or stops, at each end as described, a tiltable frame, pivoted and supported in the fixed frame at about the middle of its length, and weighted at its front end, and having a bed over which logs may slide as described; means for guiding said logs lengthwise of said tiltable frame, the latter being held normally depressed or inclined downward in the direction of travel of the logs, as shown and described.

2. An apparatus for the purpose specified, comprising a tiltable frame which is pivoted at or near its middle, and means for adjusting its pivoted bearings vertically, whereby the said frame may be adjusted bodily higher or lower and set at any required inclination transversely, substantially as shown and described.

3. An apparatus for the purpose specified, comprising the pivoted discharger or frame lateral trunnions projecting from said frame at or near its middle, trunnion guides or supports adapted for sliding vertically and screws connected with such supports for adjusting the latter higher or lower, substantially as shown and described.

4. An apparatus for the purpose specified, comprising the pivoted discharger-frame central trunnions for such pivoted frame, bearings for said trunnions which are in turn provided with lateral gudgeons, a frame in which said bearings are pivoted, guide-posts having slots or ways in which said frames are adapted to slide vertically, and screws connected with the said frame and working in nuts fixed in the posts, substantially as shown and described.

5. An apparatus for the purpose specified, comprising a discharger-frame pivoted at or near its center and tiltable as specified, and a screw top or buffer which is adjustable vertically and arranged beneath the end of said frame for arresting and supporting the same when in use, as shown and described.

6. An apparatus for the purpose specified, comprising a fixed supporting-frame, a tiltable frame pivoted therein, and devices arranged on such tiltable frame and adapted to move laterally, and springs bearing upon said devices and serving to hold them pressed normally inward over a portion of the bed, for receiving a log or other freight between them and yielding and guiding the log in the manner described.

7. An apparatus for the purpose specified, comprising a pivoted tiltable frame and dogs or guide-blocks pivoted upon the sides of said frame, and means for holding them projected inward over the bed of said frame, their rear ends being approximated for the purpose of receiving or engaging a log or other freight, substantially as shown and described.

8. An apparatus for the purpose specified, comprising a pivoted and tiltable discharger-frame, and dogs pivoted upon the side bars of the same and springs engaging said dogs for holding them projected normally into the path of the log or other freight received upon the frame, substantially as shown and described.

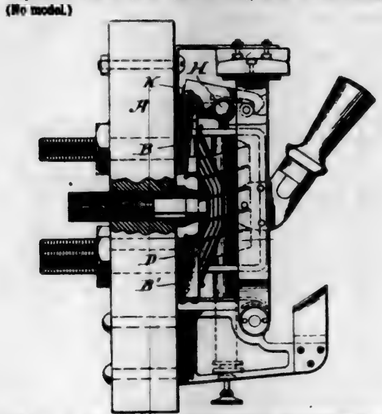
9. An apparatus for the purpose specified, comprising a frame having pivoted dogs whose rear ends are adapted to engage hooks or grapples by which the logs or other freight are suspended and carried, substantially as shown and described.

10. An apparatus for the purpose specified, comprising a pivoted tiltable frame having dogs pivoted upon the upper side of the same and their front ends being of angular form and springs for holding the dogs normally in position to receive and engage the log or other freight, substantially as shown and described.

11. An apparatus for the purpose specified, comprising a frame, bars pivoted at their front ends upon the upper sides of said frame, and dogs pivoted to said bars, and springs for holding both bars and dogs in the position required for yielding engagement with a log or other freight, substantially as shown and described.

12. In an apparatus substantially as described, the combination with a tiltable frame pivoted at or near its middle and weighted at its front end, of dogs which are pivoted to bars and the said bars in turn pivoted upon the said frame, stops for arresting both bars and dogs, and springs for pressing them inward, in the manner described.

707,952. CIRCUIT-BREAKER. FREDERICK RENSINGER, Union Hill, N. J., assignor to General Incandescent Arc Light Company, a Corporation of New York. Filed Jan. 29, 1902. Serial No. 91,738. (No model.)



Claim.—1. In an automatic circuit-breaker, the combination of a switch-lever, a latch for said lever, mechanism for lifting the latch a limited distance, and mechanism for releasing the latch.

2. In an automatic circuit-breaker, the combination of a switch-lever, a latch for said lever, mechanism energized by a magnet for releasing said latch, and mechanism interposed between said latch and magnet mechanism for aiding said magnet mechanism to release the latch.

3. In an automatic circuit-breaker, the combination of a switch-lever, a latch carrying a pivoted lever adapted to coact with said switch-lever, and mechanism for acting upon said pivoted lever and latch to release the switch-lever.

4. In an automatic circuit-breaker, the combination of a pivoted latch, a pivoted lever carried in said latch, a pivoted arm located under such latch and lever, and means for causing an upward movement of said arm.

5. In an automatic circuit-breaker, the combination of a pivoted latch, a pivoted lever carried in said latch and having its fulcrum near to the forward end of the latch and the long end of said lever normally situated below the under surface of said latch, and means for causing an upward movement of said lever and latch.

6. In an automatic circuit-breaker, a pivoted latch having a recess in the under portion of its forward end, and provided with a lever pivoted in said recess in such manner that the long end of the lever will normally lie below the under surface of the latch.

707,953. DEPILATING COMPOUND. HORACE S. BLISS, Omaha, Nebr. Filed Oct. 17, 1901. Serial No. 79,010. (No specimens.)

Claim.—1. The herein-described composition of matter for removing superfluous human hair and preventing the subsequent growth thereof, the same consisting of calcium oxid or quicklime, arsenic sulfid and hyposulfite of soda, in substantially the proportions stated.

2. The herein-described composition of matter for removing human hair and preventing the subsequent growth thereof, the same consisting of about eighty to ninety-two parts calcium oxid, eight to twenty parts of arsenic sulfid and ten parts sulfite of soda mixed with water to form a thick paste.

707,954. DEPILATING PROCESS. HORACE S. BLISS, Omaha, Nebr., assignor to himself, Ezra H. McCutcheon, Holstein, Iowa, and Fred C. McCutcheon, Iowa City, Iowa, copartners under firm-name of International Chemical Company, Iowa City, Iowa. Filed Feb. 10, 1902. Serial No. 93,220. (No specimens.)

Claim.—1. The process of retarding or destroying the growth of hair upon the human body, consisting in the removal of the hair from above the surface of the skin and subsequently applying a paste consisting of sulfur and hyposulfite of soda mixed with oil of turpentine.

2. The herein-described process of weakening or destroying the growth of human hair, consisting in the removal of the hair from above any part of the surface of the body, subsequently applying a composition consisting of sulfur and hyposulfite of soda, mixed with oil of turpentine to form a paste of sufficient consistency to adhere to the skin; and in finally removing said paste.

3. The process of weakening or destroying the hair growth consisting in the removal of hair from the surface of the human body by means of hair-dissolving chemicals; then removing said chemicals and the dissolved hair; then applying a composition consisting of sulfur, hyposulfite of soda and oil of turpentine to form a paste; and then finally removing said paste.

4. The process of enfeebling or destroying the growth of hair upon the human body, consisting in applying a composition composed of calcium oxid and arsenic sulfid mixed with water to form a paste; then removing said paste after the hair is dissolved; then rinsing the parts to which the paste has been applied in water after a period of from ten to forty minutes; then applying a composition consisting of sulfur and hyposulfite of soda mixed with oil of turpentine to form a paste; and subsequently removing said last-mentioned paste.

5. The process of enfeebling or destroying the growth of hair upon the human body, consisting in applying a composition consisting of calcium oxid, and arsenic sulfid mixed with water to form a thick paste for dissolving the hair above the surface of the skin; then removing said composition from the skin and cleansing the skin by rinsing in water; then applying a composition composed of sulfur, hyposulfite of soda and oil of turpentine; and finally removing said last-mentioned composition.

707,955. DEPILATING COMPOUND. HORACE S. BLISS, Omaha, Nebr., assignor to himself, Ezra H. McCutcheon, Holstein, Iowa, and Fred C. McCutcheon, Iowa City, Iowa, copartners under firm-name of International Chemical Company, Iowa City, Iowa. Filed Feb. 15, 1902. Serial No. 94,155. (No specimens.)

Claim.—1. The herein-described composition for destroying the roots or follicles of hair in the human skin, the said composition consisting of sulfur, hyposulfite of soda and oil of turpentine, in substantially the proportions stated.

2. The herein-described composition for permanently destroying the roots or follicles of human hair, said composition consisting of about sixty parts of sulfur, thirty parts hyposulfite of soda and ten parts of oil of turpentine.

707,956. HEAD-COVERING. AUGUST BOUILLY, Chicago, Ill. Filed Feb. 12, 1902. Serial No. 93,736. (No model.)

Claim.—In a head-covering having an opening formed in the crown thereof, a ring encircling said opening on the upper side of the crown and carrying peripheral projections bent downwardly and passing through the crown, a second ring arranged on the interior of the crown and secured in position by engagement with said projections, and an imperforate plate of translucent material arranged in the said opening between the rings, and extending entirely over the opening for admitting light to the interior of the covering but excluding air, and a shutter hinged to the second ring for excluding the light.

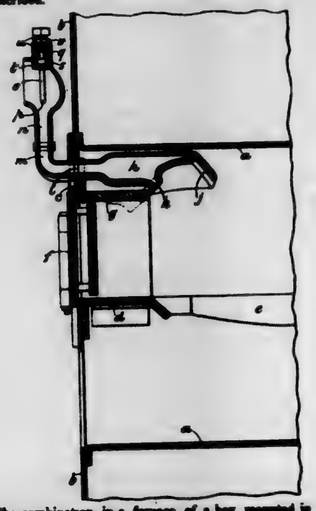
707,957. SMOKE-CONSUMING APPARATUS FOR STEAM-BOILER OR LIKE FURNACES. ROBERT D. BEATT, London, England, assignor of one-half to Thomas Percival Wood, London, England. Filed June 9, 1902. Serial No. 110,984. (No model.)

Claim.—1. A smoke consuming or preventing device for steam-boiler and like furnaces, comprising a shallow box having superposed slits inclined respectively away from and toward the center line of said box, and means for conducting air under pressure to the interior of said box, substantially as described.

2. The combination, in a furnace, of a shallow box mounted in the upper part of said furnace, said box having slits formed therein at different levels and inclined respectively away from and toward the center line of said box, an outward extension of said box having approximately the same cross-section as said box, and having a flaring aperture, a steam-pipe arranged centrally in said flaring aperture, said steam-pipe having a flattened flaring aperture, substantially as described.

3. The combination, in a furnace, of a shallow box mounted in the upper part of said furnace, said box having narrow laterally-extended slits formed therein at different levels and inclined respectively away from and toward the center line of the said box, said slits opening substantially

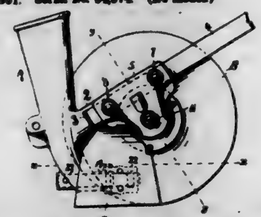
in the direction in which the gases flow through the furnace, and means for conducting air under pressure into the interior of said box, substantially as described.



4. The combination, in a furnace, of a box mounted in the upper part of said furnace, said box having narrow laterally-extended slits formed therein at different levels and inclined respectively away from and toward the center line of said box, said slits opening substantially in the direction in which the gases flow through the furnace, a pipe forming an outward extension of said box and corresponding approximately in cross-section with said box, said pipe having a flaring aperture, and a steam-pipe arranged centrally in said aperture and having a laterally-extended and flared slit, substantially as described.

5. A smoke consuming or preventing device for steam-boiler and like furnaces, comprising a shallow box having a pair of converging slits facing forwardly and arranged at different levels, and a pair of divergent slits also facing forwardly but arranged on the same level as each other, said slits being arranged symmetrically to each other, and means for conducting air under pressure into the interior of said box, substantially as described.

707,958. GRAIN-DRILL. GEORGE W. COUPER, East Moline, Ill., assignor to the Fuller Manufacturing Company, East Moline, Ill. Filed Dec. 4, 1901. Serial No. 84,674. (No model.)



Claim.—1. In combination with a seed-spout having a forwardly-extending arm at its lower end, a disk mounted to rotate in advance of said spout, a support pivotally connected to said arm the pivotal axis of said support being vertical, a scraper on the outer side of and carried by said support and bearing against one side of the disk, and a spring connected to said spout and to said support at a point in advance of the pivot of the latter on the inner side thereof, substantially as described.

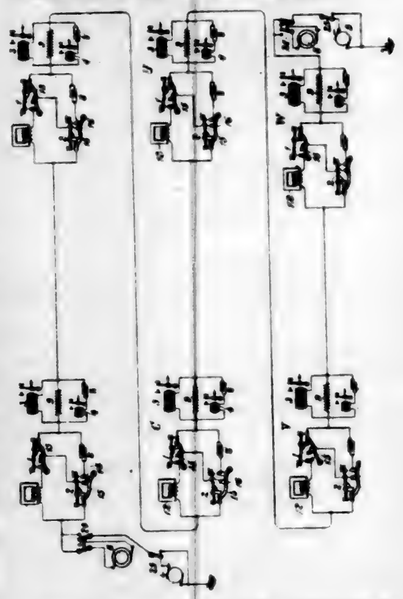
2. In combination with a seed-spout having its lower end laterally inclined and provided with a forwardly-extending arm, a disk, a support pivotally connected to said arm, the pivotal axis of said support being vertical, a scraper on the outer side of and carried by said support and bearing against the convex side of the disk, and a spring connected to said spout and to said support, at a point in advance of the pivot of the latter, on the inner side thereof, substantially as described.

3. In combination with a seed-spout, having a forwardly-extending arm at its lower end, a concavo-convex revolvable disk, a spring-pressed scraper bearing on the concave side of the disk and attached to one side of the spout and a spring-pressed scraper pivotally connected to said arm and bearing on the convex side of the disk, substantially as described.

4. A seed-spout having the rearward-extending arm 18 and the forward-extending arm 19 at its lower end, in combination with a disk a scraper-plate, a support therefor pivotally connected to said arm 19, a spring connected to said support and bearing against said scraper-plate, and a screw connecting the rear end of said spring to said arm 18, substantially as described.

5. A seed-spout having the rearward-extending arm 18, the forward-extending arm 19 and the bearing-rib 20 between said arms, in combination with a disk, a scraper-plate, a support therefor pivotally connected to said arm 19, a spring connected to said support and bearing on said bearing-rib and against said scraper-plate, and an adjusting-screw connecting the rear end of said spring to said arm 18, substantially as described.

707,959. TELEGRAPHY. ALBERT G. DAVIS, Tarrytown, N. Y. Filed Oct. 21, 1901. Serial No. 79,385. (No model.)



Claim.—1. In a superposed-current telegraph, the combination with a continuous-current receiver and pulsating-current receiver in shunt relation to one another upon the main line as described and having a condenser in the branch containing the pulsating-current receiver, of transmitters for the two sides of the system placed in branches or portions of the circuit independent of the branches containing said receivers.

2. In a superposed-current telegraph, the combination of a continuous-current receiver in a shunt or branch of the main line, a pulsatory-current receiver in a shunt or branch of the main line, a condenser in said main-line shunt, and a transmitting apparatus for the continuous-current side of the system in a branch or portion of the circuit outside of both receiver branches.

3. In a superposed-current telegraph, the combination substantially as described upon the same line, of means for producing pulsatory currents for sending one class of signals over said line, pulsatory-current receivers for said signals, continuous-current receivers for the continuous-current side of the system, and branches around the coils of said continuous-current receivers forming non-inductive shunts of comparatively low resistance, as and for the purpose described.

4. In a pulsatory-current telegraph, the combination of a continuous-current receiver in a branch of the circuit continually closed, a shunt to said receiver containing a pulsatory-current receiver and condenser, and a non-inductive resistance in multiple-arc relation to the branches of the circuit containing respectively said pulsatory-current and continuous-current receivers.

5. In a superposed-current telegraph, the combination of a pulsatory-current receiver and a continuous-current receiver in shunt relation to one another, a condenser in the branch with the pulsatory-current receiver and a non-inductive resistance in a shunt around the continuous-current receiver.

6. In a superposed-current telegraph, the combination with the continuous-current receivers, of non-inductive protective shunts connected directly around the receiver-coils and of comparatively low resistance as described so as to protect the said receiver from the disturbing action of pulsatory or variable currents and to also permit the system to be operated with pulsatory currents of comparatively small strength, as and for the purpose set forth.

7. In a superposed-current telegraph, the combination with the continuous-current receivers and their condenser-shunts for the pulsatory currents, of protective non-inductive shunts for said continuous-current receivers adapted to shunt the condenser discharge and to permit pulsatory current to flow down the line to the more distant stations.

8. In a superposed-current telegraph, the combination with a continuous-current receiver and a condenser in shunt to the same for forming a path around said receiver for the pulsatory-current side of the system, of a protective non-inductive shunt to said receiver adapted to form a diverting path for the discharge of the condenser whereby said receiver may be protected from disturbance from the condenser discharge.

9. In a superposed-current system of telegraphy, receiving apparatus for the continuous and pulsatory current sides of the system comprising a pulsatory-current receiver and condenser in one branch of the circuit, a direct-current receiver in a branch forming a shunt to said pulsatory-current receiver and condenser, and a compensating shunt around the direct-current receiver adapted to afford a path for diverting the discharge-currents of the condenser around the said direct-current receiver, as and the purpose described.

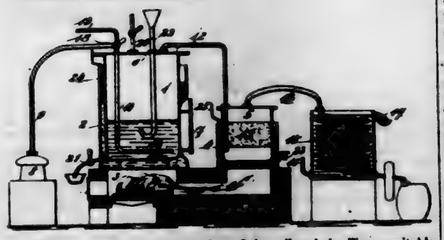
10. In a superposed-current telegraph, the combination with a pulsatory-current generator adapted to generate electromotive force of the sine-wave type, a continuous-current receiver, a non-inductive shunt to said receiver, a continuous-current transmitter in the main line outside of the said shunt, and a shunt or branch around both the transmitter and receiver containing a condenser and an inductance.

11. In a superposed-current telegraph, the combination with the continuous-current receivers at a way-station, of an artificial shunt containing a condenser and an inductance in series with one another.

12. In a superposed-current telegraph, the combination with the continuous-current transmitter and receiver apparatus at a way-station, of an artificial shunt taken around both the transmitter and the receiver containing a condenser and inductance in series with one another.

13. The combination in a superposed-current telegraph with the continuous-current transmitter, of a shunt thereto containing a condenser and inductance and an artificial load-coil in the branch with the transmitter for interposing artificial inductance when the key rests to shunt the branch or shunt containing the condenser.

707,960. APPARATUS FOR REFINING OILS. EDOUARD DUBLEY, La Garenne-Colombes, France. Original application filed June 14, 1901, Serial No. 64,585. Divided and this application filed Sept. 9, 1901. Serial No. 74,782. (No model.)

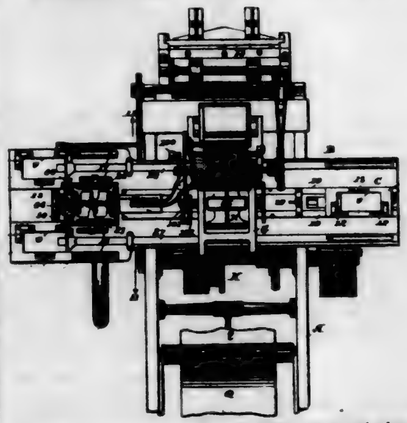


Claim.—1. In an apparatus for refining oil and the like, a suitable purifying or filtering apparatus, means for heating the same, a serpentine connected to said purifying or filtering apparatus, a suitable source of steam-supply, means connected thereto for subjecting the mass under treatment to the action of the steam, an alembic, and means connected thereto for subjecting the mass under treatment to alcoholic vapors, substantially as described.

2. In an apparatus for refining oil and the like, the combination of a furnace, a tank 1, a tank 2 surrounding said tank 1, a vessel 5 arranged in a casing forming a space between said vessel, an alembic, a pipe connected to said alembic and passing through the cover of said tank 1, extending downwardly into said tank, said pipe being bent near the bottom of tank 1 and having perforations formed therein, a pipe 12 forming an outlet from tank 1 at its top and downwardly extending into the bottom of said vessel 5, a filtering agent in said vessel 5, an outlet-pipe 14 connected with a serpentine arranged within a suitable vessel, and a suitable outlet, all parts being arranged substantially as shown for the purpose set forth.

3. In an apparatus for refining oil and the like, a tank, a tank of less diameter mounted therein, an alembic, a pipe connected thereto and extending into said inner tank, a pipe communicating with a suitable steam-supply and connected to said pipe, a purifier comprising a tank mounted within a tank, a furnace for heating both of said outer tanks, a cooling-serpentine within a suitable vessel connected to said purifier, and an outlet in said vessel, substantially as described.

707,961. SORTING AND ADDRESSING MACHINE. STERLING ELLIOTT, Boston, Mass., assignor to the Elliott Company, Boston, Mass., a Corporation of Maine. Filed Jan. 19, 1900. Renewed May 11, 1901. Serial No. 59,222. (No model.)



Claim.—1. An apparatus for sorting address-plates and other articles comprising means for directing said plates to different receptacles, said plates having differently-disposed bearings arranged to determine the number of times the plates shall pass through the machine, a sorter upon the machine, and devices whereby said sorter counts with all the plates to vary the operations of the directing means, according to the positions of the bearings, substantially as described.

2. An apparatus for sorting address-plates and other articles comprising means for directing said plates to different receptacles, said plates having differently-disposed bearings, and a sorter upon the machine, devices whereby said sorter varies the operations of the directing means, according to the positions of the bearings, and means whereby the relative positions of the plates and sorter may be changed from time to time, substantially as described.

3. In an apparatus for sorting address-plates and other articles, having differently-arranged bearings, the combination of devices for distributing said plates to different receptacles, a sorter upon the machine adjustable progressively to different positions to count progressively with different bearings, and devices intermediate the sorter and the plate-distributing devices for varying the action of the latter, substantially as described.

4. In an apparatus for sorting address-plates and other articles having bearings, differently and progressively arranged, the combination of plate shifters or distributers for moving different plates in different directions, a sorter progressively adjustable upon a moving part of the machine and adjustable to count progressively with the bearings, and means controlled by said sorter for throwing the shifters into and out of operation upon the plates, substantially as described.

5. In an addressing-machine, the combination of a receptacle for a series of printing-plates having bearings progressively disposed according to the number of times for which the plate is to be used, means for bringing the plates successively into printing action, plate shifters or distributers for directing the plates in different directions, a sorter carried by a moving part of the machine and progressively adjustable to different positions to count with the bearings, and means for varying the action of the shifters according to the relative positions of the sorter and bearings, substantially as described.

6. A sorting-machine provided with a receptacle for plates to be sorted, means for feeding the plates successively therefrom, means for

shifting the plates to distribute them in different directions and a sorting device constructed to coact with differently-disposed bearings of the plates to bring into action the shifting means, substantially as set forth.

7. A sorting-machine provided with a receptacle for plates to be sorted, means for feeding the plates successively therefrom, means for shifting the plates to distribute them in different directions and to reverse them in so doing, a sorting device constructed to coact with differently-disposed bearings of the plates to bring into action the shifting means, and receptacles to which the sorted plates are directed, substantially as set forth.

8. The combination in a sorting and printing machine, of a receptacle for printing-plates, printing means, devices for feeding the plates successively from the receptacle to the printing means, shifting means for directing the plates in different directions from the printing means, and sorting devices coacting with the plates to vary the action of the sorting devices, substantially as set forth.

9. The combination with means for feeding onward a succession of plates having bearings differently disposed, to regulate the number of times each plate shall pass through the machine, a means for shifting the plates in different directions, and a sorting device constructed to coact with all the plates to control the action of the shifting means, substantially as set forth.

10. The combination with means for feeding onward a succession of plates having regulating-bearings differently disposed, of a shifting or distributing device provided with arms arranged to carry the plates in different directions, and a sorting device and connections whereby to bring the different arms into action, substantially as set forth.

11. The shifting or distributing device consisting of rock-shafts provided with arms extending in different directions beneath a path traversed by a succession of plates, a sorting device coacting with the plates, and connections whereby to control the rock-shafts from the sorting device, substantially as set forth.

12. The shifting or distributing device consisting of rock-shafts provided with arms extending in different directions beneath a path traversed by a succession of plates, catches or detents for holding the plates on the arms, a sorting device coacting with the plates, and connections whereby to control the rock-shafts from the sorting device, substantially as set forth.

13. The shifting or distributing device consisting of rock-shafts provided with arms extending in different directions beneath a path traversed by a succession of plates, catches or detents for holding the plates on the arms, a sorting device coacting with the plates, connections whereby to control the rock-shafts from the sorting device, and detents to engage the plates delivered thereto by the arms, substantially as set forth.

14. The combination with means for feeding forward a succession of plates having bearings differently arranged, of a sorter provided with an adjustable pin and support therefor adapted to make contact with said bearings, means for reciprocating said pin and support, and distributing means controlled from said sorter, substantially as set forth.

15. The combination with the shifting or distributing means, of a sorter provided with a reciprocating arm, and a pin adjustable thereon, substantially as set forth.

16. The combination with the shifting or distributing means, of a sorter provided with a reciprocating arm having a series of openings, and a pin adapted to said openings, substantially as set forth.

17. The combination of the table having different channels, means for feeding a succession of plates in said channels, means for conveying the plates from one channel to another, and a sorter and connections for controlling the action of said means, substantially as set forth.

18. The combination of a receptacle for holding a series of plates, means for removing the plates successively from the bottom of said receptacle, other receiving-receptacles, sorting and distributing devices, and means for feeding the sorter-plates successively to the said receiving-receptacles and below the plates therein, substantially as set forth.

19. The receiving-receptacles arranged above feeding-channels for the plates, and provided with plates 29 having inclined forward edges, substantially as set forth.

20. The receiving-receptacles arranged above feeding-channels for the plates, and provided above said channels with plates 29 having inclined forward edges combined with pushers having shoulders for engaging the plates, substantially as set forth.

21. The distributing-receptacle having a base with an opening for the descent of plates therethrough, a channel below said opening, and a downward central projection o' at the end of the opening, combined with a pusher-bar having inclined upper faces and a pusher-shoulder, substantially as set forth.

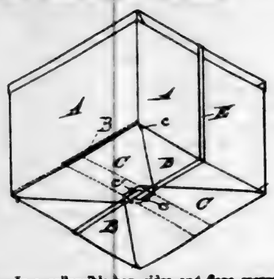
22. The combination of the plate feeding and shifting devices, a sorter having a reciprocating arm and adjustable pin, a movable contact-plate arranged in position to contact with the said pin, and connections between said plate and the shifting devices, substantially as set forth.

23. The combination with the rock-shafts of the shifting device, of pinions thereon, racks engaging said pinions, a sorter, and connections for controlling the operations of the racks, substantially as set forth.

24. The combination of the rock-shafts, pinions and racks having lugs, a reciprocating pawl, a sorter, and connections whereby the pawl is shifted by the action of said sorter, substantially as set forth.

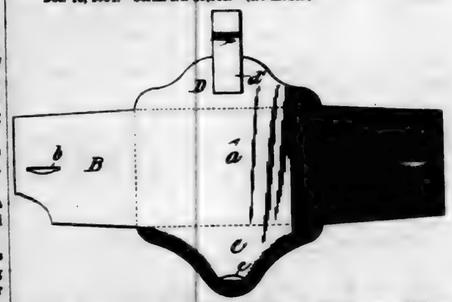
25. The combination of the rock-shafts, pinions, racks, provided with lugs having inclined upper edges, reciprocating pawl, sorter, and connection for shifting the pawl by the action of said sorter, substantially as set forth.

707,962. COLLAPSIBLE BOX. OTTO FEIL, Atlanta, Ga. Filed Apr. 9, 1902. Serial No. 102,072. (No model.)



Claim.—In a collapsible box, sides and flaps secured thereto and adapted to fold across the rectangle bounded by said sides when formed and to lap their inner edges, one pair of opposite flaps being each provided with two holes adapted to register when said sides are lapped and the other opposite pair being each provided with one hole adapted when said sides are lapped to register with the hereinbefore-mentioned registered holes and of such length as to reach when lapped just up to the holes in each other, and a tape passed through the three holes in conjunction in contact with the ends of the last-named flaps and fastened.

707,963. ENVELOP. JOHN R. FITZGERALD, Boston, Mass. Filed Dec. 10, 1901. Serial No. 85,305. (No model.)

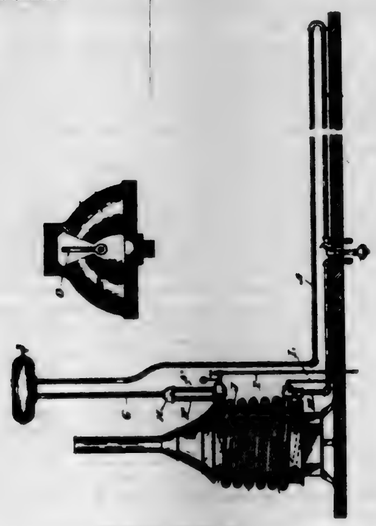


Claim.—An envelop consisting of a body portion, having side flaps and a bottom flap adapted to be folded over and secured together, each of said flaps having a slit, all of the slits registering when the flaps are folded, said body portion having a top flap provided with a tongue, said tongue adapted to carry adhesive substance, said slits being of similar shape and having straight upper edges and their lower edges at an intermediate point being recessed whereby the tongue may be passed through the registering slits, the clean side of the tongue passing along the straight upper edges of the slits, the parallel ends of the slits holding the tongue in position and the recessed lower edges of the slits permitting the adhesive substance to pass within the envelop without being scraped off.

707,964. CAR-HEATING SYSTEM. ERNEST H. GOLD, Chicago, Ill. Filed Sept. 17, 1900. Serial No. 30,267. (No model.)

Claim.—1. In a car-heating system, the combination with two independent heaters and a circulating system in operative contact with both of said heaters and adapted to be separately or simultaneously heated thereby, of a current-controlling valve interposed at a common junction between said heaters and said circulating system adapted to be closed against the inlet from either of said heaters to said junction whenever the other heater is in operation, and to be moved to a mid-position between

the inlets to said junction from each of said heaters when both of said heaters are in operation and to be supported when in said closed positions and when in said mid-position by a part of the structure, substantially as described.



2. In a car-heating system, the combination with a circulating system, of two independent heaters each of which forms a part of the circulating system, a current-controlling valve located at the common point of junction between said heaters and the circulating system, and adapted to be automatically operated by the current moving from either or both of said heaters into the circulating system, to prevent short-circuiting, said valve when at rest being wholly supported by a portion of the structure, substantially as described.

3. In a car-heating system, the combination with two independent heaters, of a pipe connected to each of said heaters and to a casing, valve-seats formed on the upper end of each pipe, a single pipe connected to said casing communicating with said heater-pipes through the casing, and a flipper-valve pivoted in the casing below said valve-seats and adapted to be seated on one of said seats on one pipe when the current in the other pipe is rising, and adapted to engage the other seat on the other pipe when the current is rising in the first-named pipe, and adapted to assume a vertical position when the current is rising in both pipes simultaneously, substantially as described.

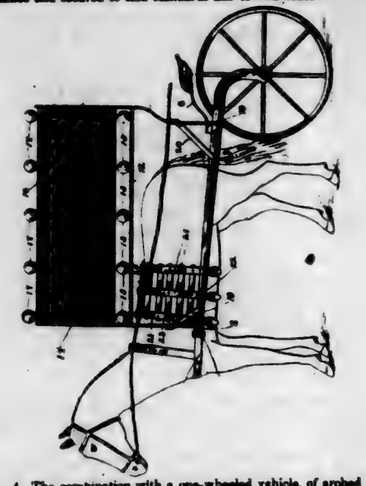
4. In a car-heating system, the combination with two independent heaters, of a pipe connected to each of said heaters, a casing connected to the upper ends of each of said pipes and communicating therewith, a single pipe connected to said casing at an intermediate point above said heater-pipes and communicating therewith through the casing, valve-seats formed on the upper ends of said heater-pipes, a flipper-valve pivotally mounted in said casing below the valve-seats, adapted to be seated on one of said seats when the current in the other pipe is rising, and adapted to engage the other seat when the current is rising in the first-named pipe, and adapted to assume a vertical position when the current is rising in both pipes simultaneously, whereby its weight is borne by the pivotal connection and its vertical position maintained by the equalization of the current-pressure in each side thereof, substantially as described.

707,965. COMBINED ROAD-CART AND INSECT-CATCHER. MARTIN B. GOODE, Vicksburg, Miss. Filed Mar. 3, 1902. Serial No. 96,432. (No model.)

Claim.—1. The combination with a one-wheeled vehicle, of a net coated with adhesive substance and mounted centrally over the thills of the vehicle and a series of lights arranged around said netting.

2. The combination with a one-wheeled vehicle, of arched bars secured to and extending upwardly from the thills of the vehicle, a net covered with adhesive substance mounted upon said arched bars and a series of lights surrounding said net.

3. The combination with a one-wheeled vehicle, of arched bars secured to and extending above the thills of said vehicle, standards mounted upon and extending upward from the center of the arched bars, a brace connecting the upper ends of said standards, a net coated with adhesive substance and secured to said standards and to said brace.



4. The combination with a one-wheeled vehicle, of arched bars extending upwardly from and secured to the thills of the vehicle, braces secured to said bars and to said thills, a brace connecting the arched bars at the top, standards projecting upwardly from the center of the arched bars, a brace connecting the upper ends of the standards, a net coated with adhesive substance secured to the said standards, and to the brace connecting the upper ends of the standards and a series of lights secured upon the last two named braces.

707,966. RAIL-JOINT. GEORGE GORDON, Luther, Mich., assignor of one-fourth to Thomas P. Magrane, Chicago, Ill. Filed Apr. 30, 1902. Serial No. 105,353. (No model.)

Claim.—1. In a rail-joint, the combination with a pair of cross-ties, of side plates secured to said ties, a bed-plate intermediate the ties, seats formed on the bed-plate to rest on the ties, adjoining rails resting on the ties and the bed-plate, and bolts securing the rails and the side plates together, substantially as described.

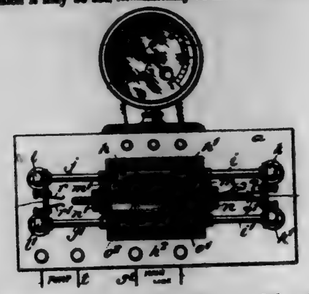
2. In a rail-joint, the combination with a pair of side plates, each plate having a depression, ways and a spring-seat, a bed-plate, bolts securing the side plates and the bed-plate together, a device for locking the nuts of the bolts against rotation, said device comprising a slide seated in the depression, guided therein by ways and held by the spring-seat, substantially as described.

3. In a rail-joint, the combination with a pair of side plates, each plate having ways and a spring-seat, a bed-plate, bolts securing the side plates and the bed-plate together, a device for locking the nuts of the bolt against rotation, said device comprising a slide guided by the ways and held by the spring-seat, substantially as described.

707,967. AUTOMATIC SWITCH FOR ELECTRIC PUMPS. ALFRED C. GRISCOM, New York, N. Y., assignor of one-half to Richard Collings, New York, N. Y. Filed Nov. 12, 1901. Serial No. 81,962. (No model.)

Claim.—In combination, a main-line circuit, a pump-circuit, a pressure-gage, a solenoid and contact-pieces at the opposite ends of the solenoid, the core of the solenoid being so located with respect to the said contact-pieces that it will make circuit through one set and break circuit through another set at each movement of the core, thereby simultaneously making or breaking circuit through the pump and breaking circuit through the solenoid, substantially as set forth.

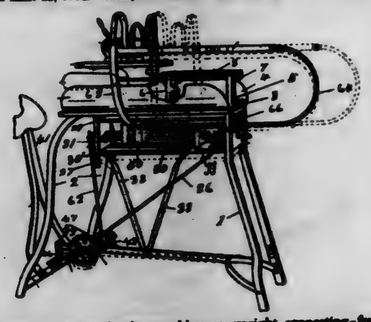
2. In combination, a mean-line circuit, a pump-circuit, a pressure-gage, a solenoid and means under the control of the gage for energizing the solenoid and thereby making and breaking the pump-circuit, the said means comprising a vibrating tongue fixed to move with the gage-arbor, an arm for swinging the gage-arbor together with the vibrating tongue into any position within the limits of the gage and contact-pieces carried by the said arm for limiting the vibratory movement of the tongue in any position in which it may be set, substantially as set forth.



3. The combination with the reciprocating core of the solenoid, of an auxiliary core having a limited movement on the main core, substantially as set forth.

4. The combination with the solenoid, its core and yielding jaws for receiving the opposite ends of the core, of an auxiliary core having a limited initial movement along the main core for imparting a driving movement to the main core to release it from the contact-jaws, substantially as set forth.

707,968. IRONING-MACHINE. Isaiah Harer, Van Wert, Ohio. Filed Mar. 18, 1901. Serial No. 51,941. (No model.)



Claim.—1. In an ironing-machine, an upright supporting-frame surmounted by a fixed table; a vertically-movable frame arranged within said upright frame beneath said table; a right and left screw-threaded shaft revolubly mounted in said movable frame; means for actuating said shaft; a carriage loosely mounted on said shaft and provided with a split nut suspended therein and adapted for a meshing engagement with but one side of said shaft at a time, whereby the said carriage is effected a longitudinal movement thereon; means for automatically reversing the movement of said carriage at predetermined limits of its travel; means for normally holding said nut to its actuating engagement; a sectional ironing-board revolubly mounted on said table as described; lateral shields fixed on said table as shown; an iron supported by said carriage normally suspended above and in cooperative relation with the said board; and means for actuating the said vertically-movable frame to bring the said iron into operative relation with the said ironing-board.

2. An ironing-machine consisting of an upright supporting-frame; a horizontal screw-shaft having right and left screw-threads revolubly and yieldingly mounted in said frame; means for rotating said shaft and for imparting thereto a limited vertical movement; a carriage mounted on said shaft and adapted to be actuated thereby in opposite directions; means for automatically reversing said carriage at each limit of its travel; a sectional ironing-board rotatably mounted on said frame as described; and an iron supported from said carriage and normally suspended above said board and in cooperation therewith.

3. The combination of an upright frame; a right and left handed screw-shaft rotatably mounted and yieldingly supported in said frame; means for rotating said shaft, and means for imparting thereto a limited vertical movement; a carriage movably mounted on said shaft and adapted to be actuated thereby in opposite directions; means for automatically reversing said carriage at each limit of its travel; an ironing-board mounted on said frame; an iron yieldingly supported above and in cooperative relation with said board; and means for rigidly connecting the said iron with the said carriage.

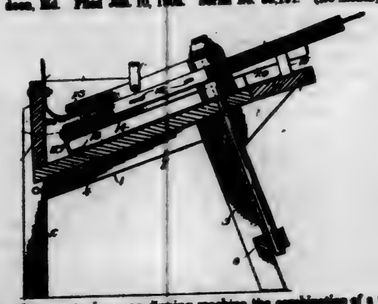
4. In an ironing-machine of the class specified, mechanism for imparting to the iron a reciprocating motion in a horizontal plane consisting of a horizontal shaft having right and left handed screw-threads; a carriage movably mounted on said shaft, and provided with a split nut adapted to alternately engage the said shaft upon opposite sides for the purpose of actuating the said carriage in opposite directions; means for automatically reversing the said carriage at each limit of its travel; and means for rigidly supporting the said iron upon the said movable carriage.

5. In an ironing-machine means for actuating the iron to and fro in a horizontal plane, consisting of a horizontal screw-shaft having right and left handed threads; a carriage movably mounted thereon and provided with a pivoted split nut whose threaded jaws are adapted for an alternate actuating engagement with the said shaft whereby the said carriage is alternately actuated in opposite directions; means for rotating the said shaft; means for automatically reversing the movement of said carriage at each limit of its travel; means for reversing the movement of said carriage at any desired point in its travel; and means for firmly supporting the said iron upon the said carriage.

6. In an ironing-machine, an ironing-board consisting of radial sections pivotally mounted upon a revolvable shaft as described, and means for locking the said board in any desired position.

7. In an ironing-machine means for supporting a movable iron consisting of a rotatable screw-shaft having right and left hand threads; a carriage movably mounted on said shaft and provided with a pivoted nut having oppositely-arranged threaded jaws adapted for a meshing engagement with the said shaft alternately as described; means for normally holding said nut in its engagement; and means for supporting said iron upon said carriage.

707,969. CAN-DIPPING MACHINE. Louder Harbinson, Chester, Pa., assignor to John F. Wells and Ernest W. Bennett, Aberdeen, Md. Filed Jan. 10, 1902. Serial No. 89,191. (No model.)



Claim.—1. In a can-dipping machine, the combination of a trough, designed to contain a liquid, a can-engaging wheel set at an inclination and extending into the trough, and a curved guide or way also set at an inclination and arranged concentric with the wheel and extending into the liquid to submerge the cans, substantially as described.

2. In a can-dipping machine, the combination of a trough, designed to contain a liquid, a can-engaging wheel set at an inclination and extending into the trough and provided with means for engaging cans, and an inclined way or guide extending into the trough below the surface of the liquid to submerge the cans and arranged adjacent to the wheel, substantially as described.

3. In a can-dipping machine, the combination of a liquid-receiving trough, an inclined can-engaging wheel, a guide or way arranged at an inclination and located adjacent to the wheel and extending beneath the surface of the liquid and adapted to receive, support and submerge the cans, and an adjustable guard arranged at the top of the guide or way and adapted to hold the cans in position, substantially as described.

4. In a can-dipping machine, the combination of a liquid-receiving trough, an inclined can-engaging wheel provided at intervals with fingers, an inclined guide or way extending into the trough below the surface of the liquid and adapted to receive and submerge the cans and located beneath the fingers, and a guard located above the fingers, substantially as described.

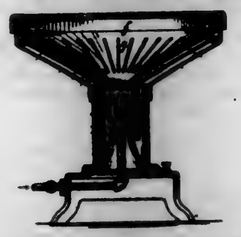
5. In a can-dipping machine, the combination of a trough having an inclined bottom, a can-engaging wheel arranged at an inclination and extending into the trough, and a curved guide or way arranged concentric with the lower portion of the wheel and extending into the trough, substantially as described.

6. In a can-dipping machine, the combination of a trough, a can-engaging wheel, a guide or way arranged adjacent to the wheel, and an adjustable guard arranged at the top of the guide or way and provided with a strainer for covering the top of the cans to retain the solid contents in the latter, substantially as described.

7. In a can-dipping machine, the combination of a trough, a can-engaging wheel, a guide or way arranged adjacent to the wheel, and a guard arranged at the top of the guide or way and provided with a strainer-strip having openings and forming a top wall for covering the cans to prevent the solid contents of the latter from escaping, substantially as described.

8. In a can-dipping machine, the combination of a frame having a trough provided with an inclined bottom, a can-engaging wheel arranged at an inclination and extending into the trough, the curved guide or way mounted upon the inclined bottom of the trough and having end extensions and composed of a bottom rail, a rear side or wall, and the short front walls arranged at the extensions of the guide or way and located at opposite sides of the wheel, substantially as described.

707,970. HEATER, RADIATOR, OR STOVE. Thomas P. Kinman, Brooklyn, N. Y., assignor of one-half to Frederick W. Sparks, Brooklyn, N. Y. Filed Feb. 28, 1902. Serial No. 96,726. (No model.)



Claim.—1. As a new article of manufacture, a gas heating device comprising a chamber having a plurality of conical walls and exit-openings for the gas, a mixer having a deflector extending downwardly within the same from the central chamber, and a gas and air supply for the mixer.

2. A gas heating device comprising a central chamber with a plurality of walls, said chamber provided with exit-openings, and a mixing-chamber located outside the central chamber and having a deflector leading the mixture away from the central chamber, so that the mixing is complete before the combustible enters the said central chamber.

3. A gas heating device having a chamber with burner-openings and a mixer comprising an outer wall open at the bottom, an inner frusto-conical or tapering tube secured at its lower edge to the lower edge or bottom of the outer wall, and a deflector closed at top and open at bottom and made to extend part way down between the outer wall and the taper tube, so as to compel air and gas rising or entering by way of the taper tube to descend before entering and rising in the outer wall.

4. A gas heating device having a chamber with burner-openings and a mixer comprising an outer wall with open top, a tapered tube open at top and bottom and made to fit the bottom of the outer wall, and a deflector made to dip down between the tube and outer wall and separate from said tube.

5. A conical chamber having oppositely-located combustion-openings, and means forming a mixing-chamber for supplying combustible to and for supporting the central chamber.

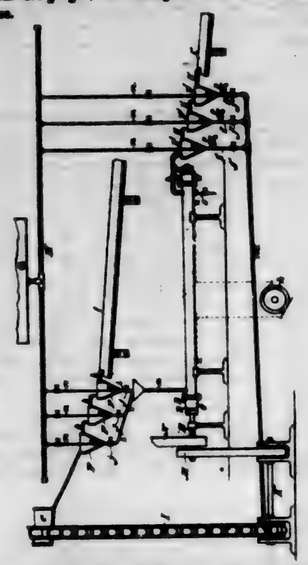
6. A conical or upwardly-expanding chamber having oppositely-located combustion-openings for throwing heat outwardly and downwardly and also inwardly and upwardly, combined with a mixing-chamber.

7. A heating device comprising outer and inner conical chambers provided with oppositely-located burner-openings, a mixer outside of and made to communicate with the chambers, a deflector, and gas and air supplies for the mixer.

8. A gas heating device, consisting of a chamber formed of a plurality of walls and provided with gas-exit openings, a mixing-tube for supporting said chamber a deflector connected to said walls and depending downwardly within and separated from said mixing-tube and a suitable gas and air supply therefor.

707,971. METHOD OF AMALGAMATING METALS. Paul A. Krapff, Greenville, Ga., assignor, by mesne assignments, to American Amalgamating Company, a Corporation of Georgia. Filed Mar. 3, 1902. Serial No. 97,231. (No specimens.)

Claim.—1. The method of amalgamating metals which consists in causing pulp to traverse an amalgamating-space containing mercury, forcibly intermingling the mercury and the pulp during its passage therethrough, removing the gangue from said space, separating the heavier particles from said gangue, and causing them to retraverse the amalgamating-space.



2. The method of amalgamating metals which consists in forming a pulp, forcibly intermingling the same with mercury, removing the gangue therefrom, separating the heavier particles from said gangue, and conducting the heavier particles thus separated to the lagging pulp.

3. The method of amalgamating metals which consists in forming a pulp, forcibly intermingling the same with mercury, removing the gangue therefrom, separating the heavier particles from said gangue, condensing the particles thus separated to the lagging pulp and concentrating the pulp and heavier particles before entrance into the amalgamator.

4. The method of amalgamating metals which consists in causing a pulp to traverse a restricted amalgamating-space containing mercury, forcibly intermingling the mercury and the pulp during its passage therethrough, removing the gangue from said space, separating the heavier particles from said gangue and causing them to retraverse the amalgamating-space.

5. The method of amalgamating metals which consists in separating the heavier metallic particles from the gangue and causing their repeated passage again through the amalgamating-space and their repeated intermingling with the mercury therein until amalgamation is effected.

6. The method of conducting the amalgamation of metals which consists in separating the heavier particles from the gangue, causing a repeated circulation of the same through the amalgamating-space and an enforced intermingling with the mercury until amalgamation is effected, and withdrawing from such circulation those particles unsusceptible to amalgamation.

7. The method of conducting a continuous amalgamation of metals which consists in causing the passage of pulp through a confined mercury-containing space, forcibly intermingling the mercury and pulp by agitation of the same, removing the gangue from said space, extracting the heavier particles from said gangue, causing said heavier particles to be returned again into the mercury-containing space, and subjecting them to intermingling with the mercury therein.

8. The method of amalgamating metals which consists in causing a pulp to traverse under pressure an amalgamating-space containing mercury, forcibly intermingling the mercury and the pulp during its passage therethrough, removing the gangue from said space, separating the heavier particles from said gangue and causing them to retraverse the amalgamating-space.

9. The method of amalgamating metals which consists in forming a pulp, causing a passage of said pulp under pressure through a mercury-receptacle, forcibly intermingling the mercury and pulp during such passage, removing the gangue from said receptacle, separating the heavier

particles from said gangue, and conducting the heavier particles then separated to the ingoing pulp.

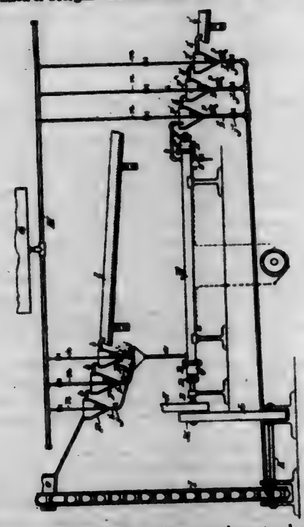
10. The method of amalgamating metals which consists in forming a pulp, causing the passage of said pulp through a mercury-receptacle, forcibly intermingling the mercury and pulp during such passage, removing the gangue from said receptacle, separating the heavier particles from said gangue, conducting the particles thus separated to the ingoing pulp, and concentrating the pulp and heavier particles before entrance into the amalgamator.

11. The method of amalgamating metals which consists in causing a pulp to traverse an amalgamating-space containing mercury, forcibly intermingling the mercury and pulp during its passage therethrough, removing the gangue from said space, separating the heavier particles from said gangue, causing them to retraverse the amalgamating-space and maintaining the activity of the mercury by an alternating current.

12. The method of amalgamating metals which consists in forming a pulp, causing the passage of the same through a mercury-receptacle, forcibly intermingling the mercury and the pulp, removing the gangue therefrom, extracting the heavier particles from said gangue, returning said heavier particles to the mercury-receptacle, and maintaining the activity of the mercury by an electric current.

13. The method of amalgamating metals which consists in forming a pulp, conducting the same into a mercury-receptacle from a position elevated therebove, causing the circulation of said pulp through said receptacle by the pressure of the superimposed pulp, intermingling the mercury and pulp, removing the gangue from said receptacle, extracting the heavier particles from said gangue, conveying said heavier particles to the ingoing pulp.

707,972. AMALGAMATOR. PARK A. KNAPP, Granville, Ga., assignor, by mesne assignments, to American Amalgamating Company, a Corporation of Georgia. Filed Mar. 8, 1902. Serial No. 97,232. (No model.)



Claim.—1. The combination with an amalgamator, having means therein for forcibly intermingling the pulp and mercury, a pulp-inlet and an outlet for the gangue, of a concentrator for extracting the heavier particles from the gangue, and conveying means to conduct said heavier particles again into the amalgamator near the inlet end thereof.

2. The combination with an amalgamator having means therein for forcibly intermingling the pulp and mercury, a pulp-inlet and an outlet for the gangue, of a concentrator for extracting the heavier particles from the gangue and conveying means to conduct said heavier particles again into the amalgamator through said pulp-inlet.

3. The combination with an amalgamator having means therein for forcibly intermingling the pulp and mercury, a pulp-inlet and an outlet for the gangue, of a concentrator for extracting the heavier particles from the gangue, conveying means to conduct said heavier particles to the ingoing pulp, and a concentrator to concentrate the ingoing pulp and heavier particles.

4. The combination of an amalgamator, a concentrator interposed between the pulp-feeder and said amalgamator, and a second concentrator to receive the gangue therefrom, and having a concentrate-discharge to said first concentrator.

5. The combination of an amalgamator having means therein for forcibly intermingling the pulp and mercury, a pulp-inlet and an outlet for the gangue, means to cause the passage of the pulp therethrough under pressure, a concentrator for extracting the heavier particles from the gangue and conveying means to conduct said heavier particles again into the amalgamator near the initial end thereof.

6. The combination of an amalgamator, having means therein for forcibly intermingling the pulp and mercury, a pulp-inlet and an outlet for the gangue, means to cause the passage of the pulp through the mercury under pressure, a concentrator for extracting the heavier particles from the gangue, and conveying means to conduct said heavier particles again into the amalgamator through said pulp-inlet.

7. The combination of an amalgamator having means therein for forcibly intermingling the pulp and mercury, a pulp-inlet and an outlet for the gangue, means to cause the passage of the pulp through the mercury under pressure, a concentrator, for extracting the heavier particles from the gangue, conveying means to conduct said heavier particles to the ingoing pulp, and a concentrator to concentrate the ingoing pulp and heavier particles.

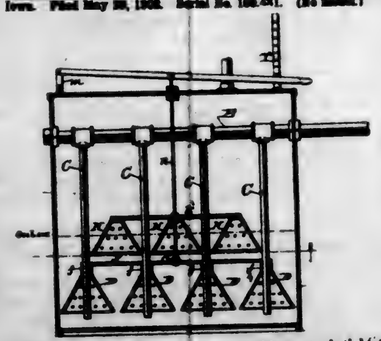
8. The combination of an amalgamator having means therein for forcibly intermingling the pulp and mercury, a concentrator to extract the heavier particles from the gangue, conveying means to return the heavier particles again to said amalgamator near the initial end thereof and means to cause the passage of an electric current through the contents of said amalgamator.

9. The combination of an amalgamator having means therein for forcibly intermingling the pulp and mercury, a pulp-inlet elevated thereabove and in free communication therewith, a concentrator for the gangue from said amalgamator and conveying means to conduct the heavier particles from said concentrator to the pulp-inlet.

10. The combination of an amalgamator having means therein for forcibly intermingling the pulp and mercury, a concentrator for extracting the heavier particles from the gangue, means for returning said heavier particles to the amalgamator to maintain a repeated circulation of the amalgamated metal therethrough, and means for withdrawing from such circulation those particles which are unsusceptible to amalgamation.

11. The combination of an amalgamator having means therein for forcibly intermingling the pulp and mercury, a concentrator to receive the gangue therefrom, and communication between said concentrator and an inlet to said amalgamator to permit the passage of the heavier particles from said concentrator again into said amalgamator.

707,973. CARBURETER. THOMAS H. J. LEONARD, Admr. Iowa, assignor of one-half to Mason City Gas and Fuel Company, Mason City, Iowa. Filed May 29, 1902. Serial No. 109,481. (No model.)

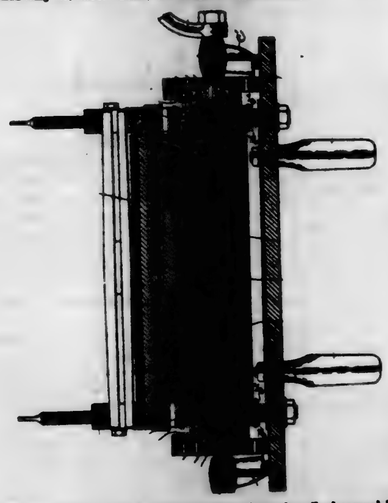


Claim.—1. In a carburetor for gas-machines, an air-tight tank, a fixed tube extending horizontally in the top portion of the tank, a plurality of tubes fixed to the horizontal tube to extend into the lower portion of the tank, elongated air-distributers fixed together and slidingly connected with the lower ends of the fixed tubes, means for raising and lowering the air-distributers and means for retaining them stationary at different points of elevation, arranged and combined to operate in the manner set forth for the purposes stated.

2. In a carburetor for gas-machines, an air-tight tank, a tube fixed in the top portion of the tank to extend horizontally, a plurality of tubes extending vertically and fixed to the horizontal tube, an air-distributer slidably connected with each fixed upright tube, means for jointly raising and lowering the distributers relative to the bottom of the tank and a plurality of air-distributers fixed on top of the distributers slidably connected with the upright tubes, to operate in the manner set forth for the purpose stated.

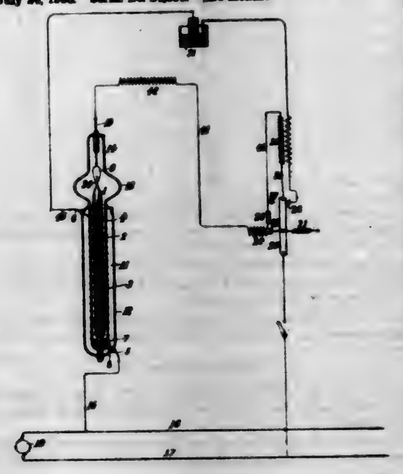
3. A carburetor for gas-machines, an air-tight tank, an air-tube fixed in its top portion to extend horizontally, a plurality of tubes fixed to the horizontal tube to extend downward, an air-distributer slidably connected with the lower end portion of each upright tube, a second series of air-distributers fixed on top of the lower distributers, a rod connected with the plurality of distributers and extended up through the top of the tank and the rod pivotally connected with the lever and a rack for retaining the lever in a fixed position, arranged and combined to operate in the manner set forth for the purposes stated.

707,974. CLOTHES-WRINGER. FRED H. PERKINS, Bridgewater, Mass., assignor of one-third to Harry E. Perkins, Bridgewater, Mass. Filed July 17, 1899. Serial No. 724,055. (No model.)



Claim.—The improved clothes-wringer above described comprising wringer-rolls, one of which has a tubular shaft; a power-driven shaft inside the tubular shaft; and pinions on the power-shaft meshing with internal gears on the tubular shaft whereby the clothes passing between the wringer-rolls are not exposed to the teeth of the gearing.

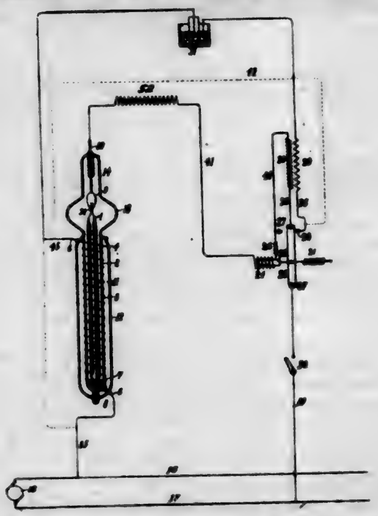
707,975. MERCURY-VAPOR LAMP. HENRY M. PORTER, Pittsburg, Pa., assignor to George Westinghouse, Pittsburg, Pa. Filed July 24, 1900. Serial No. 24,551. (No model.)



Claim.—1. The method of utilizing substantially all the luminous effect of a gas or vapor rendered and maintained incandescent by the electric current, which consists in shutting off the current from the central portion of the gas or vapor and confining its action to a path outside such central portion.

2. The method of utilizing substantially all the luminous effects of a gas or vapor rendered and maintained incandescent by the electric current, which consists in arranging the gas or vapor path in the form of an annulus and causing the current to traverse this path.

707,976. MERCURY-VAPOR LAMP. HENRY M. PORTER, Pittsburg, Pa., assignor to George Westinghouse, Pittsburg, Pa. Original application filed July 24, 1900, Serial No. 24,551. Divided and this application filed Dec. 31, 1900. Serial No. 41,606. (No model.)



Claim.—1. A gas or vapor electric lamp, having a tube containing a material or materials intended to be made incandescent by the electric current, in combination with a non-conducting material occupying the central portion of the said tube.

2. A gas or vapor electric lamp, consisting of a tube containing a material or materials intended to be made incandescent by the electric current, a cooling-chamber at one end of the said tube, and a narrowed extension of the said chamber.

3. A gas or vapor electric lamp, consisting of a tube containing a material or materials intended to be made incandescent by the electric current, a cooling-chamber at one end of the said tube, and a narrowed extension of the said chamber, one of the electrodes being located at the mouth of the narrowed extension.

4. A gas or vapor electric lamp, having a tube containing a material or materials intended to be made incandescent by the electric current, the said tube being surrounded by a vacuum-chamber in which is located a heater.

5. A gas or vapor electric lamp, having a tube containing a material or materials intended to be made incandescent by the electric current, the said tube being surrounded by a vacuum-chamber in which is located an electrical starting-heater.

6. A gas or vapor electric lamp, having a tube containing a material or materials intended to be made incandescent by the electric current, the said tube being surrounded by a vacuum-chamber in which is located a heater, the operation of which is automatically interrupted by the lighting-current.

7. A gas or vapor electric lamp, having a tube containing a material or materials intended to be made incandescent by the electric current, the said tube being surrounded by a vacuum-chamber for a portion of its length and containing an enlargement in its remaining portion.

707,977. WHEELED SCRAPER OR SCOOP. THOMAS B. RADCLIFFE, Lawrence, Kans., assignor of one-third to Charles Rich Metcalf, Lawrence, Kans. Filed Dec. 7, 1901. Serial No. 84,591. (No model.)

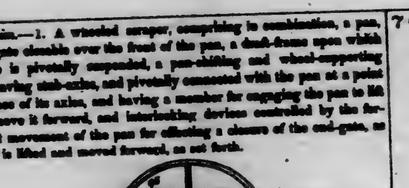
Claim.—1. A wheeled scraper, comprising in combination, a pan, an end-gate closable over the front of the pan, a draft-frame upon which the pan is pivotally suspended, a pan-shifting and wheel-supporting frame, having stub-axles, and pivotally connected with the pan at a point in advance of its axles, and having a member for engaging the pan to lift it and move it forward, and interlocking devices controlled by the forward lift movement of the pan for effecting a closure of the end-gate, as the pan is lifted and moved forward, as set forth.

2. A wheeled scraper, comprising in combination with a lift-frame the supporting-wheels, the vertically and forwardly movable pan, pivotally suspended from said frame, and the draft-frame pivotally hung on the axles; of the independently-movable end-gate pivotally suspended from the draft-frame, and mechanism cooperatively connected with the pan and draft-frame controlled by the upward and forward swing of the pan for shifting said end-gate to its closure position, when the pan is elevated for transportation, as set forth.

3. The combination with the pan, a lift-frame having side arms pivotally connected with the pan at a point in advance of the axles, said arms having the wheel-carrying axles projected therebeyond, a draft-frame pivotally joined with the axles, an independently-movable end-gate pivotally suspended from the said draft-frame, latch-hooks on the pan, latches on the draft-frame, and means for moving the said hooks and pan to an interlocking position, substantially as shown and for the purposes described.

4. The combination with the frame B, including the side members *b*, and the stub-axles projected from said members; of the pan pivotally suspended from the members *b* at a point in advance of the axles, latch-engaging hooks projected forwardly from the pan and secured thereto, and heel-bosses on the pan in the path of the swing movement of the members *b*; of the draft-frame C pivotally secured to the axles, the end-gate D, pivotally suspended from the frame B, latches on the frame C for engaging the pan-hooks, and means for swinging the end-gate to its closed position as the pan is lifted and swung forward by the action of the frame B, substantially as shown and for the purposes described.

707,978. GAP FOR BOTTLES. Frederick Esser, Brooklyn, N. Y., assignor to Rex Cap and Cork Company, New York, N. Y., a Corporation of New York. Filed Dec. 13, 1900. Renewed Feb. 21, 1902. Serial No. 93,693. (No model.)

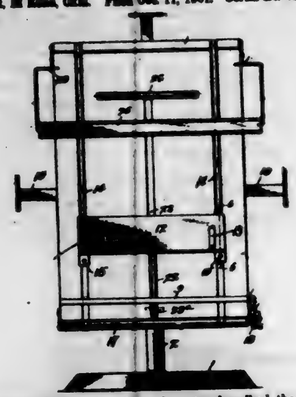


Claim.—1. The combination with a bottle, of a flanged cap for the mouth thereof, the neck of the bottle and the flange of the cap being provided with matching grooves, a wire intermediate between the neck and cap and locking the cap to the bottle by lying partly in each groove, and an opening through the flange of the cap into its groove through which the wire can be withdrawn from its locking position with both grooves, substantially as described.

2. The combination with a bottle, of a flanged cap for the mouth thereof, the neck of the bottle and the flange of the cap being provided on one side with engaging lips and on the opposite side with matching grooves, and a wire intermediate between the neck and the cap and locking the cap to the bottle by engaging the grooves in both, substantially as described.

3. The combination with a bottle of a flanged cap for the mouth thereof, the neck of the bottle and the flange of the cap being provided on one side with engaging lips and on the opposite side with matching grooves, an opening through the flange of the cap into the groove, and a wire passing through the opening and lying intermediate between the neck and the cap and locking the cap to the bottle by engaging the groove in both, substantially as described.

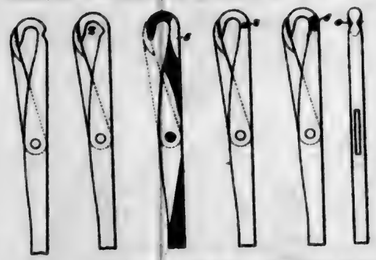
707,979. BOOK-SUPPORT OR COPY-HOLDER. Sherard W. Sawyer, St Rena, Ohio. Filed Oct. 11, 1901. Serial No. 78,370. (No model.)



Claim.—1. In a device of the character described, the combination of a book adjustably mounted upon a suitable support and having its front and rear surfaces provided with siloed longitudinal grooves, rollers mounted at the ends of the book and extending across the terminals of the grooves, a carriage disposed transversely of the front of the book, straps traveling in the grooves and secured at one end to the carriage and at the other end to one of the rollers, a ratchet device for the latter roller, operating means for the roller, and antifriction-rollers carried by the carriage and traveling in the respective grooves in the front of the book and behind the straps.

2. A device of the class described, comprising a book adjustably mounted upon a suitable support, a top and opposite side extensible arms mounted in grooves in the rear side of the book, a carriage slidable upon the front side of the book, means for adjustably moving the carriage, a ratchet device therefor, a spring constructed to return the carriage to its normal position when the ratchet is released, a marker extending transversely across the front side of the book, and provided with opposite terminal arms which are pivoted to the respective edges of the book, the marker being capable of being swung over upon the rear side of the book upon the pivotal connections of the arms as centers, and an antifriction-roller let into the front side of the book.

707,980. KNITTING-MACHINE NEEDLE. Robert W. Scott, Philadelphia, Pa., assignor of one-half to Louis H. D. Williams, Ashbourne, Pa. Filed Oct. 15, 1901. Serial No. 78,116. (No model.)



Claim.—1. A knitting-machine latch-needle having its upper portion locally weakened so as to cause breakage at a predetermined point when the hook is subjected to undue strain.

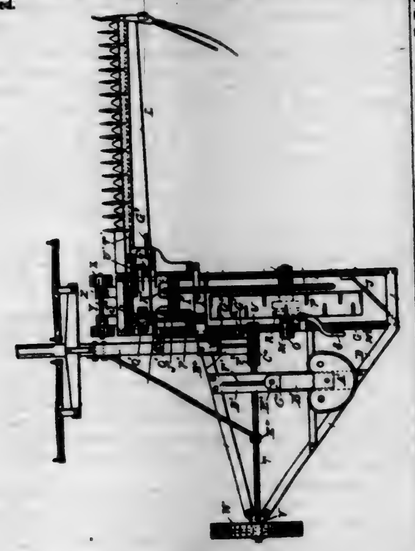
2. A knitting-machine latch-needle having its hook locally weakened whereby, when said hook is subjected to undue strain, the hook portion of the same will be broken off.

3. A knitting-machine latch-needle having the upper portion of the same recessed at a point below the head of the hook so as to locally weaken the same.

707,981. MOWING-MACHINE. Fred L. Semple, Toledo, Ohio. Filed June 10, 1899. Renewed Feb. 3, 1902. Serial No. 92,546. (No model.)

Claim.—In a mowing-machine, the combination with the supporting-frame, two wheeled axles thereon, one below and in advance of the

other, rollers at the forward end of the supporting-frame, a draft-bar having its inner end pivotally connected to the lower wheeled axle, and a brace for the draft-bar extending from the latter to and having a pivotal connection with the lower axle, substantially as and for the purpose described.



707,982. HEAD OR SEARCH LIGHT. Horace H. Taylor, San Jose, Cal., assignor of one-half to Frank J. Hayhow, San Francisco, Cal. Filed June 2, 1902. Serial No. 109,594. (No model.)

Claim.—1. A head or search light comprising a central stationary mirror or reflector and a plurality of adjustable mirrors extending around said stationary mirror or reflector, substantially as and for the purpose specified.

2. A head or search light comprising a central mirror or reflector and a plurality of supplemental mirrors or reflectors forming an extension to the central mirror or reflector, and means for adjusting the supplemental mirrors or reflectors, substantially as and for the purpose described.

3. A head or search light comprising a plurality of pivoted mirrors or reflectors, a movable ring, and suitable means connecting the mirrors or reflectors with the ring, whereby the movement thereof will change the position and angle of the mirrors or reflectors, substantially as and for the purpose set forth.

4. A head or search light comprising a stationary ring, a plurality of mirrors or reflectors pivotally connecting with the ring, a movable ring connecting with the mirrors or reflectors whereby the same may be adjusted to change their angle by the movement of the ring, substantially as and for the purpose specified.

5. A head or search light comprising a plurality of pivoted mirrors or reflectors, arms connecting with the mirrors or reflectors, a movable ring and suitable cam devices thereon to operate in connection with the arms to tilt the mirrors or reflectors on their pivotal connection to change their angle to control the direction of the rays or beams of light therefrom, substantially as and for the purpose described.

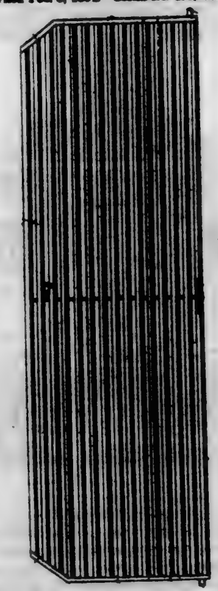
6. A head or search light comprising a central stationary mirror or reflector and a plurality of pivoted supplemental mirrors or reflectors, a movable ring and suitable cam devices thereon for changing the position of the supplemental mirrors or reflectors with relation to their angle whereby the direction of the rays or beams of light reflected thereby are controlled, substantially as and for the purpose set forth.

7. A head or search light comprising a central stationary mirror or reflector and a plurality of pivoted supplemental mirrors or reflectors forming an extension thereto, suitable arms extending from the rear sides of the supplemental mirrors, a suitable movable ring and cam devices thereon to operate in connection with the arms to change the angle and position of the supplemental pivoted mirrors and reflectors, substantially as and for the purpose described.

8. A head or search light comprising a stationary ring, a central mirror or reflector connecting therewith, a movable ring and suitable cam devices thereon, and pivoted supplemental mirrors or reflectors connecting with the ring, and arms upon the supplemental mirrors or reflectors against which the cam devices come in contact to adjust the position of the supplemental mirrors or reflectors, substantially as and for the purpose specified.

9. A head or search light comprising a stationary ring, a suitable mirror or reflector and brackets connecting the same with the ring, suitable arms on the ring, supplemental mirrors or reflectors pivotally connected thereto and forming an extension to the stationary mirror or reflector, suitable arms upon the rear sides of the supplemental mirrors or reflectors, a movable ring suitably connecting with the stationary ring, and cam devices thereon to operate in connection with the arms, substantially as and for the purpose set forth.

707,983. METALLIC SHELVING. Warren H. Taylor, Stamford, Conn., assignor to The Yale & Towne Manufacturing Company, Stamford, Conn. Filed Feb. 3, 1894. Serial No. 499,088. (No model.)



Claim.—1. As a new article of manufacture, an open trussed fireproof shelf comprising transverse end pieces, hollow bars fixed at their ends against transverse displacement upon said end pieces, trussed tie-rods having their ends fixed in the end pieces, tying said end pieces together and holding them against the hollow bars, and a transverse supporting-rod passing through all of the hollow bars, fixed with relation thereto and resting upon the trussed tie-rods; substantially in the manner and for the purposes set forth.

2. As a new article of manufacture, an open fireproof shelf comprising end pieces formed with seats, longitudinal hollow bars fitted to the seats on said end pieces in a manner to prevent transverse movement of the hollow bars on the end pieces, and a rod passing transversely through all of the hollow bars and resting upon the tie-rods and thereby affording vertical support to the hollow bars; substantially as herein set forth.

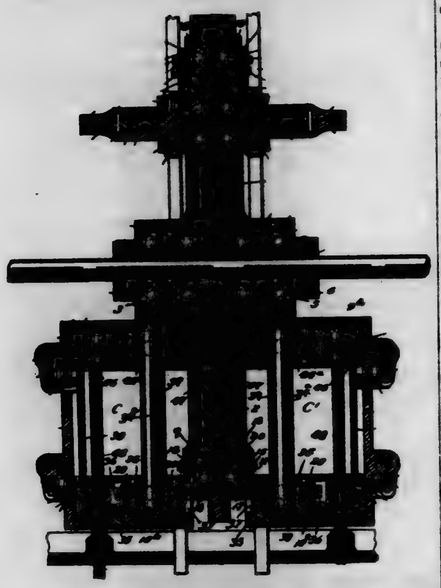
3. As a new article of manufacture, an open fireproof shelf comprising transverse end pieces having beams formed thereon providing seats, longitudinal hollow bars fitted over said bars and thereby prevented from transverse movement upon the end pieces, trussed tie-rods extending through the hollow bars, having their ends fixed in the end pieces and tying the latter rigidly against the longitudinal hollow bars, and a trans-

verse rod passing through all of the hollow bars above and resting upon the tie-rods; substantially as set forth.

4. A metallic shelf comprising a series of longitudinal hollow bars, the transverse pieces or headers in which the ends of the hollow bars are fitted and by means of which the hollow bars are supported, and the brace or tie rods, located at variable heights between the top and bottom of the pieces or headers and by which the pieces or headers are connected and adapted to impart additional support and stiffness to the hollow bars; substantially as described.

5. In a metallic shelf, the combination of the pieces or headers, the bars extending between the headers, one or more brace or tie rods also extending between and attached to the headers, and a screw-threaded stay-rod passing through the bars and engaging the brace or tie rods, at or near the center, substantially as and for the purpose set forth.

707,984. DRIVING MECHANISM FOR ROAD-VEHICLES. WILLIAM S. TAYLOR, Jr., Lima, Ohio, assignor of two-thirds to Charles Zimmerman and Lee Zimmerman, Ostwein, Iowa. Filed Nov. 20, 1901. Serial No. 83,055. (No model.)



Claim.—1. In a changeable speed-gear, a driven member, a casing surrounding the driven member, a rotary driving member mounted revolubly on the casing and concentric to the driven member, parallel shafts, fixed and movable gears on said shafts, said fixed gears connecting with the driving member and the movable gears with the driven member.

2. In a changeable speed-gear, a casing having a circular perimeter, a driven rotary member, a revolubly driving member, mounted on the perimeter of the casing, shafts, fixed and movable gears on the shafts, connecting with the driving and driven members on opposite sides thereof respectively, and means to throw the gears out of operative connection with said members.

3. In a changeable speed-gear, a casing having a circular perimeter, a driving member revolubly mounted on the perimeter of the casing, a driven member within the casing, shafts on opposite sides of and parallel with the driven member, fixed and movable gears on each shaft connecting with the driving and driven members respectively, means to throw the gears out of operative connection with said member, and means to adjust the movable gears on the shafts.

4. In a changeable speed-gear, a casing, a rotary driven member therein, a rotary driving member mounted on the perimeter of the casing, shafts on opposite sides of the driven member, fixed and movable gears, arranged to connect with the opposite side faces of the said driving and driven members respectively, and means substantially as described for adjusting the movable gears on the shafts.

5. In a changeable speed-gear, a rotary driven member, a rotary driving member arranged concentric to and in the same plane as the driven member, gear-carrying means parallel to the plane of the said members, fixed and movable gears mounted thereon and operatively engaging the driving and driven members respectively, and means substantially as described for adjusting the movable gears on the shafts.

6. In a changeable speed-gear, a rotary driven member, a rotary driving member arranged concentric to and in the same plane as the driven member, gear-carrying means parallel to the plane of the said members, fixed and movable gears mounted thereon and operatively engage the driving and driven gears respectively, and means to adjust the movable gears with relation to the driven member.

7. In a changeable speed-gear, a rotary driven member, a rotary driving member arranged concentric to and in the same plane as the driven member, gear-carrying means parallel to the plane of the said members, fixed and movable gears mounted thereon, arranged to operatively engage the driving and driven gears respectively, means to adjust the movable gears with relation to the driven member and means to throw the gears out of operative engagement.

8. In a mechanism of the character described, the combination of a casing, a rotary disk-wheel within the casing, means to rotate the disk-wheel, and brakes in the casing arranged to bear on opposite sides thereof mounted on eccentric bearings.

9. The combination of a circular casing, a revolubly sprocket-rim on the casing, a rotary disk-wheel within the casing, oppositely-disposed shafts, friction-pulleys on the shafts to engage with the sprocket-rim, and friction-pulleys on said shafts to engage with the disk-wheel.

10. The combination of a circular casing, a revolubly sprocket-rim on the casing, a rotary disk-wheel within the casing, oppositely-disposed shafts, friction-pulleys on the shafts to engage with the sprocket-rim, friction-pulleys on said shafts to engage the disk-wheel and movable lengthwise on the shafts, and means to move and hold said pulley at points to which moved.

11. The combination of a circular casing, a revolubly sprocket-rim on the casing, a rotary disk-wheel within the casing, oppositely-disposed shafts, friction-pulleys fixed on one end of the shafts to engage with the sides of the sprocket-rim, friction-pulleys slidably mounted on the other ends of the shafts to engage with the sides of the disk-wheel, means to move the pulleys laterally out of engagement and means to move and hold the slidable pulleys on the shafts.

12. The combination of a circular casing, a revolubly sprocket-rim on the casing, a rotary disk-wheel within the casing, oppositely-disposed boxes secured to the casing, laterally-movable bearings located in one end of the boxes, laterally and vertically movable bearings in the other end of the boxes, friction-pulleys in the first-named bearings, to bear on the face edges of the sprocket-rim, friction-pulleys in the second-named bearings, to bear on the faces of the disk-wheel, means to move the laterally and vertically movable bearings with the pulleys vertically, and means to move the bearings laterally.

13. In combination with the revolubly sprocket-rim, the casing, and the disk-wheel, of a reversing-gear therefor, comprising parallel shafts, pulleys on the ends of the shafts, to engage the sprocket-rim, pulleys on the opposite ends of the shafts, pulleys interposed between the last-named pulleys and the side faces of the disk-wheel, and means to move the pulleys into and out of engagement with the disk-wheel.

14. In a machine of the character described, the combination with the casing, the revolubly sprocket-rim carried by the casing, and the disk-wheel, of a reversing mechanism therefor, comprising shafts mounted parallel with the casing and disk-wheel and laterally movable in relation thereto, pulleys on the shafts to engage the sprocket-rim, pulleys on the other ends of the shaft, and pulleys between these and the disk-wheel, means to adjust the pulleys radially in relation to the disk-wheel, and means to move all the pulleys into and out of engagement with said rim and disk-wheel.

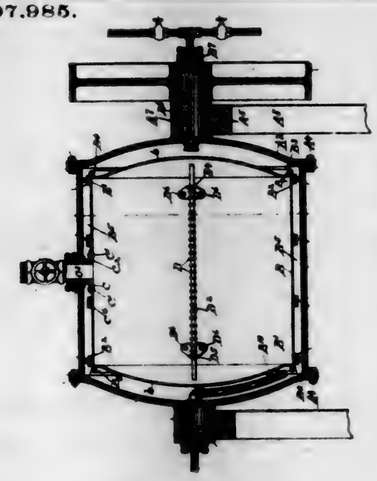
707,985. PROCESS OF MAKING LAUNDRY STARCH. CHARLES H. TILLOTSON and ABEL G. GOLDSWAIT, Troy, N. Y., assignors to William H. Tillotson & Son, Troy, N. Y., a Firm. Filed Feb. 3, 1898. Renewed July 14, 1902. Serial No. 115,963. (No specimens.)

Claim.—1. That improvement in the art of making laundry starch which consists in heating starch with water until it becomes hydrated, and then cutting and finely subdividing the mass until all structure is destroyed.

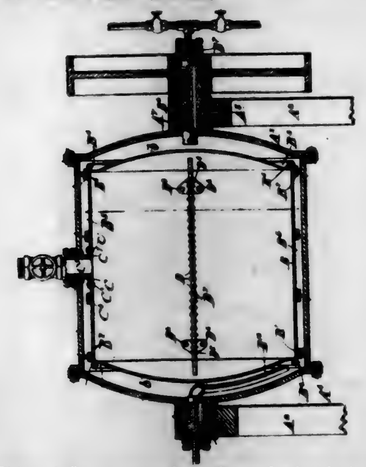
2. That improvement in the art of making laundry starch which consists in heating starch with water until it becomes hydrated, and then simultaneously cutting, finely subdividing and cooling the mass until all structure is destroyed.

3. That improvement in the art of making laundry starch which consists in simultaneously isolating from external contamination, agitating and superheating a mixture of ignitable starch and water until the starch becomes soluble and is partially dissolved, and then while so isolated simultaneously cutting, finely subdividing and cooling the isolated mass.

707,985.



707,986. APPARATUS FOR TREATING STARCH. CHARLES H. TILLOTSON and ABEL G. GOLDSWAIT, Troy, N. Y., assignors to William H. Tillotson & Son, Troy, N. Y., a Firm. Original application filed Feb. 3, 1898, Serial No. 668,686. Divided and this application filed Aug. 30, 1901. Serial No. 73,366. (No model.)



Claim.—1. In an apparatus for treating starch a drum having a series of screen-partitions extending from its inner periphery to near its center, leaving said center open for the passage of starch from one partition to the other entirely around the cylinder, and an opening leading to the space between two of the partitions, said opening being provided with means for closing the same, substantially as described.

2. In a starch-treating apparatus a starch-receiving drum rotary upon a horizontal axis and containing a screen-partition fixed in the drum and partially dividing the starch-inclosure, and means for rotating the drum.

3. An apparatus for treating starch consisting of a drum having a series of screen-partitions extending from its inner periphery to near its center, leaving said center open for the passage of starch from one partition to the other entirely around the cylinder, substantially as described.

4. An apparatus for treating starch consisting of a drum having a series of screen-partitions extending from its inner periphery to near its center, leaving said center open for the passage of starch from one partition to the other entirely around the cylinder, and an opening leading to the space between two of the partitions, said opening being closed by a valve, substantially as described.

5. The combination with an outer drum having end trunnions journaled in suitable bearings; of an inner drum; adjustable supporting connections between the cylindrical walls of the two drums for centering the inner drum; inlet and outlet pipes for permitting a heating agent to flow through the space between the drums and means for rotating the drums, substantially as described.

6. In a starch-treating apparatus, and in combination; a rotary drum with supporting-trunnions; bearings for the trunnions; means for rotating the drum; a closed starch-receiver; means for supporting the receiver within the drum with a steam-chamber between the drum and receiver; a steam-supply pipe leading through one of the trunnions to the steam-chamber; a stationary exhaust-pipe leading from the lower side of such steam-chamber out through the other trunnion, substantially as described.

707,987. LOCK-UP FOR PRINTERS' FORMS. SAML. G. TORREY, Washington, D. C., assignor of one-half to William C. Boddew, Washington, D. C. Filed July 20, 1901. Serial No. 68,810. (No model.)

Claim.—1. In a lock-up for printers' forms, the combination with two parallel movable quoin-members disposed at right angles to each other and each comprising two sections one of which is movable longitudinally and the other of which is movable laterally, said sections of each member having coacting cam-faces, of a pressure-adjusting device including a block interposed between the mutually-adjacent ends of the members and pivotally connected to the adjacent ends of the longitudinally-movable sections of the members, and means operating through said block for actuating the members substantially as described.

2. In a lock-up for printers' forms, the combination with the quoin members each comprising two sections, the one section of each member being movable longitudinally and the other section of each member movable laterally, of a pressure-adjusting device including a block pivotally connected to adjacent ends of the members, and a screw operating through said block, substantially as described.

3. In a lock-up for printers' forms, the combination with the quoin members adapted to be placed within the chase substantially at right angles to one another, of a pressure-adjusting device including a block and screw, the block pivotally connected to the adjacent end of the quoin members, substantially as described.

4. In a lock-up for printers' forms, the combination with the quoin members disposed at right angles to each other and each comprising two sections having coacting cam-faces, one section of each member movable longitudinally and the other movable laterally, of a pivotal connection between the adjacent ends of the longitudinally-movable members and means connected to the said pivotal connections for adjusting the pressure of the members on the type-form, substantially as described.

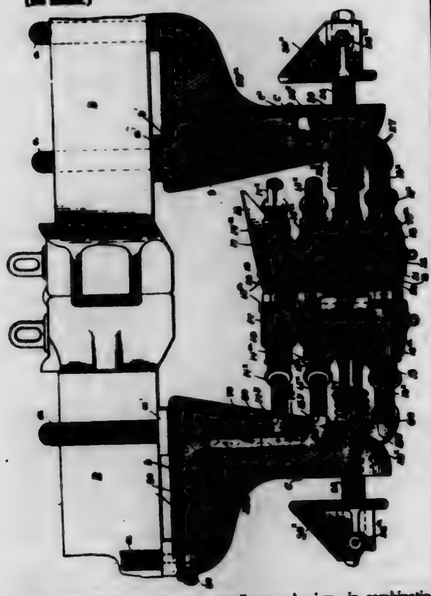
5. The combination with the quoin members each comprising two sections one section movable longitudinally and the other laterally, with means carried by the longitudinally-movable section to limit the movement of the laterally-moving section, and a pressure-adjusting device including a block, and a screw operating therethrough, the block being pivoted to the adjacent ends of the longitudinally-movable sections, substantially as described.

6. In a printer's lock-up, two quoin members adapted to be placed within a chase substantially at right angles to each other, a block placed between the adjacent ends of said members, a screw operating through said block for engagement in the corner of the chase, and links pivoted at their ends to the block and quoin members, substantially as described.

7. A lock-up for printers' forms, comprising in connection with a type-chase, quoin members which are adapted to be placed in the chase substantially at right angles, a block located between the adjacent ends of the quoin members, a screw operating through the block and engaging the type-chase, and links pivoted to the block and to the adjacent ends of the quoin members, as and for the purpose described.

8. In a printer's lock-up two quoin members adapted to be placed within a chase at substantially right angles to each other, each member comprising two sections, one section movable longitudinally and the other section of each member movable laterally, a pivotal connection between the adjacent edges of the said longitudinally-movable members, and a pressure-adjusting device pivotally secured to the said pivotal connection, substantially as and for the purpose described.

707,988. AUTOMATIC TRAIN-PIPE COUPLING. WILLIAM G THISTLEWAY, Vancouver, Canada, assignor of one-half to THOMAS A. TREMBLAY, Montreal, Canada. Filed Jan. 8, 1902. Serial No. 88,915. (No model.)



Claim.—1. In a train-pipe coupling mechanism: in combination with a suitable hanger, a coupling means supported in said hanger, comprising a solid shank fulcrumed in the hanger for vertical and lateral motion, a coupling-head attached to and supported upon the outer end of the shank to move freely in a lateral and vertical plane, said shank having means adapted to coöperate with the hanger for sustaining the shank and the head in a horizontal position, said coupling-head including flexibly-held pipe-sections, and flexible connections for joining said sections with the ordinary train-pipe, all being arranged substantially as shown and described.

2. The combination with train-pipes, the hanger 20, the coupling-head, said head having ducts for coöperating with the train-pipes, and a solid stem slidable in the hanger, means for sustaining the stem and head in a predetermined horizontal plane, and the spring for normally forcing the head and its stem forward; of the rigid pipe-sections, joined with the coupling-head ducts, with their free ends extended in a transverse plane with the hanger 20, and a flexible pipe-connection for joining the rigid pipes with the train-pipes, all being arranged substantially as shown and for the purpose described.

3. In a train-pipe coupling mechanism as described, a longitudinally-slidable coupling-head, and means for normally pressing it to its forward position; of mechanism for tilting the said head vertically, when said head is forced the limit of its outward thrust, for the purposes set forth.

4. The combination with the hanger 20, the coupling-head longitudinally slidable in said hanger, and supported therein to swing in a vertical plane; of a stop-piece on the rear end of said coupling-head, adapted to engage the hanger, and a stop adjustably held on the hanger for engaging with the upper end of the stop, for the purposes specified.

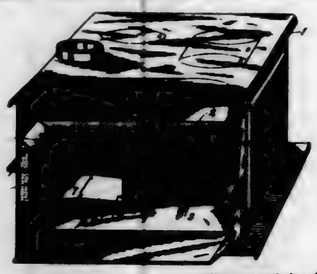
5. The combination with the vertically-slotted hanger, the coupling-head, including the stem 26 slidably mounted in the slot of the hanger and fulcrumed therein for vertical and lateral movement, the bracket or stop member fixedly secured on the rear end of the stem, the spring 27, and the stop-stud C, adjustably mounted on the hanger to engage with the stop member when the stem and head move forward, for the purposes described.

6. In a train-pipe coupling mechanism of the character described the combination with the hanger 20 for supporting the pipe coupling mechanism, said hanger including diverging side members, and a cross-head, and the draw-bar; of clip members adapted to straddle the bar, said members including distance-pieces or clip-bars, for coöperating with the threaded ends of the clips, and notched cylebolts for engaging the clip ends, and made fast to the side members of the hanger-frame, all being arranged substantially as shown and described.

7. In combination with a coupler-head, having a rectangular face with guide-horns placed on a diagonal plane at opposite flat sides of head, and bearing-points arranged on its opposite corners, and apertured nuts having gudgeons arranged in ducts on a perpendicular line across the face of said head, a detachable plate, having ducts therethrough designed to register with the ducts in said head, said plate being of the same contour as face of said head, a catch on one side of said plate designed to overlap and grip the retentive side of the head, and a slidable bolt, having a beveled inner side arranged on the opposite side of said plate in such a manner as to grip the opposite side of the head, whereby the forcing inward of said bolt, the plate and head will be clamped together.

8. In combination with a coupling-head, having its guide-horns on a diagonal plane from a vertical line and flattened edges at right angles thereto, an attaching-plate of the same form as the face of said head, having a lugged projection on one side, and a lug with a slidable locking-bolt on the other to engage the opposite flattened edges of face of said head.

707,989. STOVE OR RANGE. GEORGE A. TOURTELLOT, Salt Lake City, Utah. Filed Jan. 13, 1902. Serial No. 89,457. (No model.)



Claim.—1. In a stove or range, a partition extended vertically from the grate and movable thereon, a plate extending across the grate and having hinge connection with the partition, another plate having hinge connection with the first-named plate and hinge connection with the stove or range, and a rod for operating the partition, substantially as specified.

2. In a stove or range, a partition extended upward from the grate and movable along the same, a plate extended across the grate and having hinge connection with the lower end of the partition, another plate having hinge connection with the first-named plate and also having hinge connection with the stove or range, a rod having a portion extended from the partition through an opening in the stove, and a portion extended along the outer side of the stove, substantially as specified.

707,990. HEATING-DRUM. WILLIAM VOGEL, Hartley, Iowa. Filed Nov. 12, 1901. Serial No. 82,905. (No model.)

Claim.—1. In a heating-drum, the combination with the casing connected at its ends to the stove and smoke-pipe, horizontal plates slidably mounted therein, rods connected to said plates, and a wall at one end of the plates, substantially as shown and described.

2. In a heating-drum, the combination, of the casing connected at its ends to a stove and smoke-pipe, horizontal plates swiveled in the drum or casing, rods connected to said plates, a wall at the outer end of the plates at one side of the drum, and supports for said plates, one edge of each plate being heavier than the other, substantially as shown and described.

3. In a heating-drum, the combination, of the casing connected at its end to a stove and smoke-pipe, horizontal plates swiveled in the drum or casing and located at one end thereof, beams in the other end of the casing, scrapers mounted in the casing upon the beams, and handles connected to said scrapers, the bottom of the drum having an opening through which the soot is deposited, substantially as shown and described.

707,991. COUPLING. FRED A. WARREN, East Providence, R. I. Filed Apr. 16, 1901. Serial No. 56,491. (No model.)

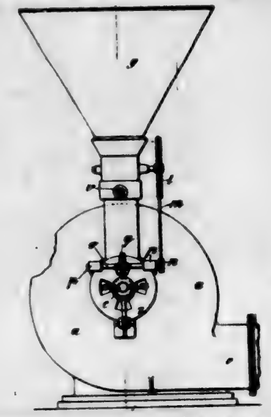
Claim.—1. In a coupling, the combination with a male member having a tapering end and an inclined contracted portion forming a vertical shoulder, of a female member having an annular chamber therein engaging said end of the male member, the rear wall of said chamber having an annular groove therein, an annular washer carrying a flange, the flange being seated in said groove in said chamber and being engaged by said tapering end of the male member, the washer engaging the inner circumference of the male and female members, enlarged portions on opposite sides of said female member having vertical openings therein, posts having lower inclined faces for engagement with said tapering portion and said shoulder of the male member, the upper ends of said posts having horizontal openings therein, a latch secured to each of said enlarged portions in an opening provided therefor on the upper face of the enlarged portion, a pin passing through said latch and secured in said enlarged portions, a rounded lug formed integral with one end of the latch and normally mounted in said horizontal openings in the posts, the other end of said latch being convex in cross-section forming a seat on its under face and a thumb-operating member on its upper face, and a spring engaging said seat and in an opening provided therefor on the upper face of said enlarged portion, an annular flange formed integral with each end of the female member, and an annular flange formed integral with the rear end of the male member for engagement with the front flange of the female member when the members are locked, substantially as described.

2. In a coupling, the combination of a male member having a tapering end and an annular flange carried in proximity to the end, of a female member having a chamber formed therein and carrying a flange at its end for engagement with said flange carried by the male member, the end portion of the male member engaging the inner circumference of said chamber in the female member, the rear wall of said chamber having an annular groove formed therein, a projection formed at the lower end of said groove, a washer having an elongated portion for engaging with the inner circumference of said male and female members, said washer carrying a flange for engagement in said groove in said chamber and said projection, the other face of said flange being engaged by said tapering end of the male member, substantially as described.

707,992. APPARATUS FOR SUPPLYING FUEL TO FURNACES. GEORGE H. WARNER, Brooklyn, N. Y., assignor, by mesne assignments to the Central Cyclone Company, Ltd., London, England, a Corporation. Filed May 20, 1901. Serial No. 62,410. (No model.)

Claim.—1. In apparatus for supplying pulverized fuel and air to furnaces, the combination of a motor-fan for supplying the air, of a hopper, of a feeding device located between the hopper and the said fan and normally supporting the body of fuel, of a device for agitating the fuel in said hopper and in contact with and operated directly by said feeding device and of means whereby the quantity of fuel supplied from the hopper to the furnace is determined by the speed of the fan, for the purpose specified.

2. In apparatus for supplying pulverized fuel and air to furnaces, the combination of a motor-fan for supplying the air, of a hopper, of a feeding device located in said hopper, of an agitating device between the hopper and the said fan and normally supporting the body of fuel in contact with and operated directly by said feeding device and of means whereby the quantity of fuel supplied to the furnace from the hopper is determined by the speed of the motor-fan for the purpose specified.



3. In apparatus for supplying pulverized fuel and air to furnaces the combination of a motor-fan for supplying the air, of a hopper, of a feeding device located between the hopper and the said fan and normally supporting the body of fuel, of an agitating device in said hopper in contact with and operated directly by said feeding device, of adjustable means for regulating the outlet of said hopper and of means whereby the quantity of fuel supplied to the furnace from the hopper is determined by the speed of the motor-fan.

4. In an apparatus for supplying pulverized fuel and air to furnaces the combination of a motor-fan, a hopper, a feeding device between the hopper and the said fan and normally supporting the body of fuel, an agitating device situated in said hopper and in contact with and operated directly by said feeding device and of gearing coupling the motor-fan with the feeding device for the purpose specified.

5. In apparatus for supplying pulverized fuel and air to furnaces, the combination of a motor-fan, of a hopper, of a feeding device between the hopper and the said fan and normally supporting the body of fuel, of an agitating device situated in said hopper and in contact with and operated directly by said feeding device, of adjustable means for controlling the quantity of fuel delivered from said hopper, and of gearing coupling the motor-fan with the feeding device for the purpose specified.

6. In apparatus for supplying pulverized fuel and air to furnaces, the combination of a motor-fan, of a hopper, of a feeding device located between the hopper and the said fan and normally supporting the body of fuel, of a conduit situated between said hopper and said fan, of an agitating-plate situated in said hopper and in contact with and operated directly by said feeding device, of an adjustable plate for controlling the outlet of said hopper and of means working in conjunction with the said fan and the said feeding device for the purpose specified.

7. In apparatus for supplying pulverized fuel and air to furnaces, the combination of a motor-fan, of a hopper, of a fluted roller located in said hopper, of a conduit situated between said hopper and the fan, of a flexible plate situated in said hopper and having its lower edge engaging with said roller, of an adjustable flexible plate situated in said hopper for regulating the outlet of said hopper and of gearing connecting the axis of said roller and the driving-shaft of said fan for the purpose specified.

8. In apparatus for supplying pulverized fuel and air to furnaces, the combination of a motor-fan, of a hopper, of a fluted roller located in said hopper, of a conduit situated between the said outlet and the fan and having air-inlet openings in its walls, of a flexible plate situated in said hopper and having its lower edge engaging with said fluted roller, of an adjustable flexible plate situated contiguous to the outlet of said hopper and said roller, of gearing connecting the said roller to the driving-shaft of the fan for the purpose specified.

9. In apparatus for supplying pulverized fuel and air to furnaces the combination of a motor-fan, of a surrounding casing for said fan having suitable air-inlet openings in its walls, of means for adjusting said inlets, of a hopper, of a fluted roller located in said hopper, of a conduit situated under the outlet of said hopper and communicating with the fan-inlet of said fan, of a flexible plate situated in said hopper and having its lower end in engagement with said fluted roller, of an adjustable flexible plate for regulating the outlet of said hopper and of gearing connecting

the axle of said roller with the driving-shaft of said fan for the purpose specified.

10. In apparatus for supplying pulverized fuel and air to furnaces, the combination of a motor-fan, of a surrounding casing for said fan having suitable air-inlet openings in its walls, of a movable perforated plate for adjusting said openings, of a hopper, of a fluted roller located in said hopper of a conduit communicating with the outlet of said hopper and with the fuel-inlet of said fan, of a flexible plate situated in said hopper and having its lower edge in engagement with said fluted roller, of an adjustable flexible plate for regulating the outlet of said hopper and of gearing connecting the axle of said roller with the driving-shaft of said fan, for the purpose specified.

11. In apparatus for supplying pulverized fuel and air to furnaces, the combination of a motor-fan for supplying the air, of a casing surrounding said fan having air-inlet openings in its walls, of a movable perforated plate for adjusting said openings, of a hopper, of a fluted roller located in said hopper, of a conduit communicating with the outlet from the hopper and with the fuel-inlet in said fan-casing, of a flexible plate situated in said hopper and having its lower edge in engagement with said roller, of an adjustable flexible plate in said hopper for regulating the said outlet, of a screw for adjusting the position of said plate relatively to said roller and of gearing connecting the axle of said roller with the shaft of said fan for the purpose specified.

12. In a machine for feeding pulverized fuel, the combination with a fan-casing and a spout communicating therewith, of a grooved feed-roller mounted in the spout, and a spring-bar having one end secured above the roller and its lower end located within the spout and extending into one or the other of the grooves of said roller, substantially as described.

13. In a machine for feeding pulverized fuel, the combination with a fan-casing and a spout communicating therewith having a hopper, of a grooved feed-roller mounted in the spout and a spring-bar mounted in the hopper and adapted to be continuously vibrated by the feed-roller, substantially as described.

14. In a machine for feeding pulverized fuel, the combination with a fan-casing and a spout communicating therewith, of a grooved feed-roller mounted in the spout and an adjustable spring-arm having a free, depending straight portion bearing with a yielding pressure against the surface of said roller, substantially as described.

15. In a machine for feeding pulverized fuel, the combination with a fan-casing and a spout communicating therewith, of a grooved feed-roller mounted in the spout, a spring-arm normally bearing against the surface of said roller and having a free depending portion extending below the same and a set-screw adapted to engage said depending portion for adjusting the position of said arm relative to the roller, substantially as described.

16. In a machine for feeding pulverized fuel, the combination with a fan-casing and a spout communicating therewith, of a horizontally-disposed grooved feed-roller mounted in the spout, a spring-arm having a depending, vertical portion normally bearing intermediate its end against the side of said roller, and a set-screw having its end engaging the free end of said spring-arm for adjusting the position of the spring-arm relative to the roller, substantially as described.

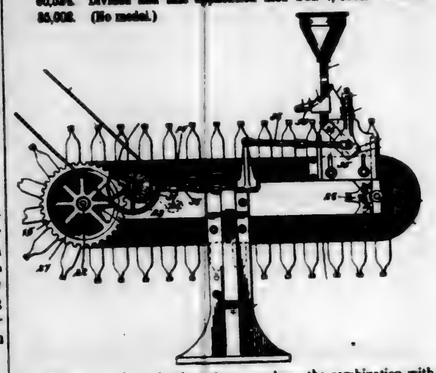
17. In a machine for feeding pulverized fuel, the combination with a fan-casing and a spout communicating therewith, of a grooved feed-roller mounted in the spout, a spring-bar having a free end extending into one of the other of the grooves of the roller, a spring-arm normally bearing with a yielding pressure against the surface of said roller, and means for adjusting the position of said arm relative to said roller, substantially as described.

18. In a machine for feeding pulverized fuel, a fan-casing, a housing surrounding the suction-opening of said fan-casing, and having an air-inlet, a chute communicating with the interior of said housing at one end, and having a feed-hopper at its opposite end, a feed-roller mounted in said chute, a rotary fan in said casing, and a driving connection between said fan and said roller, substantially as described.

19. In a machine for feeding pulverized fuel, a fan-casing, a housing surrounding the suction-opening of said fan-casing and having an air-inlet, a chute mounted upon said casing, and having above the casing an air-opening and communicating at its lower end with the interior of said housing and having a feed-hopper at its upper end, a feed-roller mounted in said chute, a rotary fan in said casing and a driving connection between said fan and said roller, substantially as described.

20. In a machine for feeding pulverized fuel, a fan-casing, a housing surrounding the suction-opening of said fan-casing and having a damper-controlled air-inlet, a chute mounted upon said casing and having above the casing an air-opening and communicating at its lower end with the interior of said housing and having a feed-hopper at its upper end, a feed-roller mounted in said chute, a rotary fan mounted in said casing, and a driving connection between said fan and said roller, substantially as described.

707,993. MACHINE FOR CORKING BOTTLES. CLINTON J. WARREN, Chicago, Ill. Original application filed May 16, 1901, Serial No. 60,594. Divided and this application filed Dec. 7, 1901. Serial No. 85,093. (No model.)



Claim.—1. In a bottle-corking machine, the combination with a movable carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, cork-inserting devices adapted to insert corks in successive bottles of said moving series, means for causing said inserting devices to move for a limited distance alongside of the moving series of bottles, and means for retracting said inserting devices in an opposite direction from that of the movement of the carrier, substantially as specified.

2. In a bottle-corking machine, the combination with a movable carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, cork-inserting devices adapted to insert corks in successive bottles of said moving series, means for causing said inserting devices to move for a limited distance alongside of the moving series of bottles, means for retracting said inserting devices in an opposite direction to that of the movement of the carrier, and means for advancing the cork in position to be acted upon by said inserting devices after each retracting movement, substantially as specified.

3. The combination with a carrier adapted to receive and hold a bottle thereon with the neck end projected, of means for continuously moving the carrier, a cork-carrying device, means for moving said cork-carrying device a limited distance alongside of the bottle and returning it to its normal position, and means for forcing a cork from said cork-carrying device into the neck of the moving bottle.

4. The combination with a carrier adapted to receive and hold a bottle thereon with its neck end projected, of means for moving the carrier, a cork-carrying device, means for giving said cork-carrying device a reciprocating motion over and in the line of travel of the bottle and to retract it therefrom, and means for forcing a cork from said cork-carrying device into contact with the top of the bottle and to retract it therefrom, and means for forcing a cork from said cork-carrying device into the neck of the bottle while in contact therewith and while said bottle is being moved with its carrier, substantially as described.

5. The combination with a frame, a carrier supported thereby and adapted to receive and hold a bottle with its neck end projected, means for moving the carrier, a cross-head suitably supported above said frame, a plunger carried thereby, and a second cross-head movable vertically in the supports of the first-named cross-head and provided with means for holding a cork, of means for forcing the cross-head carrying the cork down upon the top of the moving bottle, means for forcing down the other cross-head to bring the plunger carried thereby into contact with the cork in the cork-carrying cross-head and thereby force such cork into the neck of the moving bottle, and means for withdrawing said devices after the cork has been forced into the bottle, substantially as specified.

6. The combination with a frame, a carrier supported thereby and adapted to receive and hold a bottle with its neck end projected, means for moving the carrier, a cross-head suitably supported above said frame, a plunger carried thereby, and a second cross-head movable vertically in the supports of the first-named cross-head and provided with means for holding a cork, of means for forcing the cross-head carrying the cork down upon the top of the moving bottle, means for forcing down the other cross-head to bring the plunger carried thereby into contact with the cork in the cork-carrying cross-head and thereby force such cork into the neck of the moving bottle, means for withdrawing said devices after the cork has been forced into the bottle, and means for automatically supplying said cork-carrying cross-head with another cork after such withdrawal, substantially as specified.

7. The combination with a carrier adapted to receive and hold a bottle thereon with its neck end projected, of means for moving the carrier, a cork-carrying device, means for giving said cork-carrying device a reciprocating motion over and in the line of travel of the bottle and a descending and ascending movement to bring said cork-carrying device into contact with the top of the bottle and to retract it therefrom, means for forcing a cork from said cork-carrying device into the bottle while in contact therewith and while said bottle is being moved with its carrier, a receptacle for containing a quantity of corks, and means for feeding from said receptacle a single cork to the cork-carrying device each time that said cork-carrying device is drawn to the limit of its backward and upward motion, substantially as specified.

8. The combination with a carrier adapted to receive and hold a bottle thereon with its neck end projected, of means for moving the carrier, a cork-carrying device, means for giving said cork-carrying device a reciprocating motion over and in the line of travel of the bottle and a descending and ascending movement to bring said cork-carrying device into contact with the top of the bottle and to retract it therefrom, means for forcing a cork from said cork-carrying device into the bottle while in contact therewith and while said bottle is being moved with its carrier, a receptacle for containing a quantity of corks, means for feeding from said receptacle a single cork to the movable cork-carrying device each time that said cork-carrying device is brought to the limit of its upward and rearward movement, and means carried by said movable cork-carrying device for setting in operation the means for forcing a cork from the receptacle containing a supply of corks into the movable cork-carrier, substantially as specified.

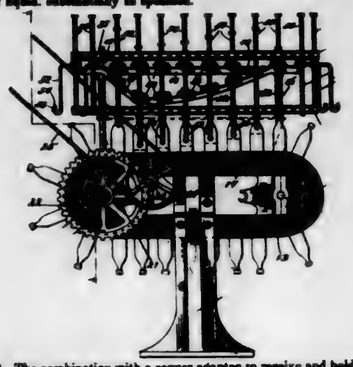
9. The combination with a carrier adapted to receive and hold a bottle thereon with its neck end projected, of means for moving the carrier, a cork-carrying device, means for giving said cork-carrying device a reciprocating motion over and in the line of travel of the bottle and a descending and ascending movement to bring said cork-carrying device into contact with the top of the bottle and to retract it therefrom, means for forcing a cork from said cork-carrying device into the bottle while in contact therewith and while said bottle is being moved with its carrier, a receptacle for containing a quantity of corks, means for feeding from said receptacle a single cork to the movable cork-carrying device each time that said cork-carrying device is brought to the limit of its backward and rearward movement, means connected with said movable cork-carrying device for setting in operation the means for forcing a cork from the said receptacle into the movable cork-carrier, and a connection between said movable cork-carrier and the means for supplying corks from the receptacle whereby upon the downward and forward movement of the cork-carrier a single cork will be dropped into position and the parts for ejecting corks locked until the next upward and rearward movement of the cork-carrier has been effected, substantially as specified.

10. The combination with a carrier adapted to receive and hold a bottle thereon with its neck end projected, of means for moving the carrier, a cork-carrying device, means for giving said cork-carrying device a reciprocating motion over and in the line of travel of the bottle, and at the same time a descending and ascending movement to bring said cork-carrying device over and in line with the top of the bottle and to retract it therefrom, a stationary receptacle for containing a supply of corks, a tube connected with said receptacle at its upper end and at its lower end with a chamber, a plunger within said chamber adapted to be drawn back to permit a cork from said tube to be draped in front of said plunger, a connection between said cork-carrier and said plunger whereby said plunger is retracted as the cork-carrier moves away from it means connected with said cork-carrier for releasing said plunger from its retracted position when said cork-carrier is at its upper and rearward position, and means for forcing said plunger forward to move the cork in front of it into said cork-carrier, substantially as specified.

707,994. BOTTLE-FILLING MACHINE. CLINTON J. WARREN, Chicago, Ill. Original application filed May 16, 1901, Serial No. 60,594. Divided and this application filed Dec. 7, 1901. Serial No. 85,093. (No model.)

Claim.—1. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a liquid-reservoir, a movable filling device adapted to fill said bottle while said bottle is moving, and means for passing said filling device into and through said reservoir during the operation of filling the bottle, substantially as specified.

2. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a liquid-reservoir, a movable filling device adapted to fill said bottle while said bottle is moving, means for passing said filling device into and through said reservoir during the operation of filling the bottle, and means for withdrawing said filling device from the reservoir and shutting off the flow of liquid, substantially as specified.



4. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a liquid-containing reservoir, a device for filling said bottle while it is moving, means for forcing said device into said bottle and also into said reservoir, means for moving said filling device through said reservoir while engaged with said bottle, and means for causing a flow of liquid through the filling device into the bottle while said carrier is being moved, substantially as specified.

5. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a liquid-containing reservoir, a device for filling said bottle while it is moving, means for forcing said device into said bottle and also into said reservoir, means for moving said filling device through said reservoir while engaged with said bottle, means for gradually varying the position of the filling device in the bottle and at the same time maintaining its connection with the reservoir, and means for causing a flow of liquid through the filling device from the reservoir into the bottle, substantially as specified.

6. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a liquid-containing reservoir, a device for filling said bottle while it is moving, means for forcing the filling device into said moving bottle and into the reservoir, means for moving said filling device through the reservoir parallel with the moving carrier and in engagement with the bottle, means for causing a flow of liquid through the filling device while said carrier and the bottle thereon are moving, and means for withdrawing said filling device from the moving bottle and reservoir and shutting off the flow of liquid through the filling device, substantially as specified.

7. The combination with a carrier mounted on a horizontal axis adapted to receive and hold a series of bottles with their neck ends projected, of means for moving said carrier, a second carrier mounted on a vertical axis and consisting of an endless chain, means for moving the said chain, a series of filling devices carried by said second carrier, means for causing said filling devices to successively engage successive bottles on said first-named carrier, means for causing a flow of liquid through said filling devices to fill said bottles while the same are being moved, and means for disengaging the filling devices from the bottles and shutting off the flow of liquid without stopping the movement of the bottle-carrier, substantially as described.

8. The combination with a bottle-carrier, and means for moving said carrier, of an endless chain located above said bottle-carrier, means for moving said chain, a series of filling devices carried by said chain and adapted to be successively brought over bottles carried by said bottle-carrier, means for causing said devices to engage such bottles, means for causing a flow of liquid through said filling devices to fill said bottles while the same are being moved, and means for disengaging the filling devices from the bottles and shutting off the flow of liquid without stopping the movement of the bottle-carrier, substantially as specified.

9. The combination with a bottle-carrier adapted to receive and hold a series of bottles, and means for moving said carrier, of a chain located above said bottle-carrier, means for moving said chain, a series of filling devices carried by said chain and adapted to be successively brought over bottles carried by said bottle-carrier, said filling devices having a vertical movement, means for causing said filling devices to successively enter suc-

cessive bottles on said bottle-carrier, means for causing a flow of liquid through said devices when such devices are within the bottles, and means for withdrawing said devices from the bottles and shutting off the flow of liquid without stopping the movement of said bottle-carrier, substantially as specified.

10. The combination with a bottle-carrier adapted to receive and hold a series of bottles, and means for moving said carrier, of a chain located above said bottle-carrier, means for moving said chain, a series of filling devices carried by said chain and adapted to be successively brought over bottles carried by said bottle-carrier, said filling devices having a separate vertical movement, trolleys attached to said filling devices, a track for said trolleys to run upon, said track being inclined at one portion to cause the filling devices to descend and enter the bottles on the moving carrier, means for causing a flow of liquid through said devices when such devices are within the bottles, and means for withdrawing said devices from the bottles and shutting off the flow of liquid without stopping the movement of said bottle-carrier, substantially as specified.

11. The combination with a bottle-carrier adapted to receive and hold a series of bottles, and means for moving said carrier, of a chain located above said bottle-carrier, means for moving said chain, a series of filling devices carried by said chain and adapted to be successively brought over bottles carried by said bottle-carrier, said filling devices having a separate vertical movement, trolleys attached to said filling devices, a track for said trolleys to run upon, said track being inclined at one portion to cause the filling devices to descend and enter the bottles on the moving carrier and also inclined to cause a withdrawal of the said devices from such moving bottles, means for causing a flow of liquid through such filling devices when said devices are within the bottles, and means for shutting off the flow of liquid as they are being withdrawn from the moving bottles, substantially as specified.

12. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a siphon-tube having its discharge end located above the line of travel of the moving bottle, means for moving said tube parallel and at equal speed with the bottle, means for forcing the said discharge end of the siphon-tube into the bottle, a valve carried by the other or receiving end of the siphon-tube and adapted to open said end when submerged in a body of liquid, a liquid-containing tank into which said receiving end of the siphon-tube is adapted to enter, and means for withdrawing the said ends from the bottle and tank respectively, substantially as described.

13. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a siphon-tube having its discharge end above the line of travel of the moving bottle, a track or guide having a double inclined portion parallel with the line of travel of the moving bottle, means for supporting said siphon-tube on said track, means for moving said siphon-tube down and up said inclined track, whereby the said discharge end of the siphon-tube will be caused to gradually enter and be withdrawn from the moving bottle, a valve carried by the other or receiving end of the siphon-tube and adapted to open said end when submerged in a body of liquid, and a liquid-containing tank into which said receiving end of the siphon-tube is adapted to enter when moving on the inclined portion of the track, substantially as specified.

14. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a siphon-tube, a track having a double inclined portion, a trolley adapted to run on said track and connected at one side to each siphon-tube, means for forcing said trolley along said track, whereby when it passes along the double inclined portion the discharge end of said siphon-tube will gradually enter and be withdrawn from the bottle, a liquid-containing tank adapted to receive the other end of the siphon-tube while said trolley is on the inclined portion of the track, means for admitting liquid to the siphon-tube when said last-named end is in the tank, and means for closing said tube when withdrawn from the tank, substantially as described.

15. The combination with an endless carrier adapted to receive and hold a series of bottles with their neck ends projected, of means for continuously moving said carrier, an endless track located above said continuously-moving endless carrier and having at the side nearest the endless carrier a double inclined portion parallel with the line of travel of said endless carrier, a series of siphon-tubes movably mounted on said track, means for continuously moving said series of siphon-tubes so that as they pass down and up the double inclined portion of the track one end of each will successively enter and be withdrawn from one of the series of continuously-moving bottles, a liquid-containing tank into which the opposite end of each of said siphon-tubes is adapted to enter at the time said tubes travel on the double inclined portion of the track, means for admitting liquid to the bottles from said siphon-tubes while said tubes are in said bottles and in said tank, and means for stopping the flow of liquid through the siphon-tubes as said tubes are withdrawn from the bottles and the tank, substantially as specified.

16. The combination with a bottle-carrier and means for moving said carrier, of an endless chain located above said bottle-carrier, means for moving said chain, a series of siphon filling-tubes carried by said chain and adapted to be brought over bottles carried by said bottle-carrier, means for causing said tubes to engage such bottles, a liquid-containing means into which one end of the siphons is forced and moved therethrough to cause the filling of the bottles while the same are being moved, and means for disengaging the filling-tubes from the bottle and shutting off the flow of liquid without stopping the movement of the bottle carrier.

17. The combination with a bottle-carrier adapted to receive and hold a series of bottles and means for moving said carrier, of a chain located above the bottle-carrier, means for moving said chain, a series of siphon filling-tubes carried by said chain and adapted to be successively brought over bottles carried by said bottle-carrier, said siphon filling-tubes having a vertical movement, means for causing said filling-tubes to successively enter successive bottles on said bottle-carrier, a liquid-containing means into which one end of the siphons is forced and moved therethrough to cause the filling of the bottles while the same are being moved, and means for disengaging the filling-tubes from the bottle and shutting off the flow of liquid without stopping the movement of the bottle-carrier.

18. The combination with a bottle-carrier adapted to receive and hold a series of bottles, and means for moving said carrier, of a chain located above said bottle-carrier, means for moving said chain, a series of siphon filling-tubes carried by said chain and adapted to be successively brought over bottles carried by said bottle-carrier, said filling-tubes having a vertical movement, trolleys attached to said filling-tubes, a track for said trolleys to run upon, said trunk being inclined at one portion to cause the filling-tubes to descend and enter the bottles on the moving carrier a liquid-containing means into which one end of the siphons is forced and moved therethrough to cause the filling of the bottles while the same are being moved, and means for disengaging the filling-tubes from the bottle and shutting off the flow of liquid without stopping the movement of the bottle-carrier.

19. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a stationary liquid-reservoir, a movable filling device independent of said reservoir and adapted to fill said bottle while said bottle is moving, and means for forcing said filling device simultaneously into said bottle and into said liquid-reservoir and for withdrawing said filling devices simultaneously from said bottle and liquid-reservoir, substantially as specified.

20. The combination with a carrier adapted to receive and hold a bottle with its neck end projected, of means for moving said carrier, a stationary liquid-reservoir, a movable filling device adapted to fill said bottle while said bottle is moving, means for forcing said filling device simultaneously into said bottle and into said liquid-reservoir and for withdrawing said filling device simultaneously from said bottle and liquid-reservoir, and means for gradually varying the position of the filling device in the bottle during the travel of the latter and at the same time maintaining its connection with the reservoir.

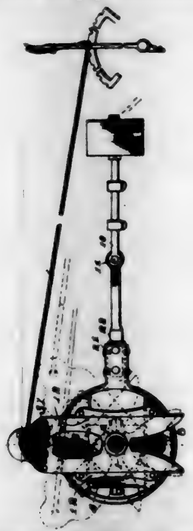
707,995. VALVE-GEAR. HENRY WHITE and WILLIAM G. TAYLOR, Marion, Ohio, assignors of one-third to Zachariah Taylor Silvis, Greensburg, Pa., and Harry J. Silvis, Mansfield, Ohio. Filed Sept. 23, 1901. Serial No. 76,262. (No model.)

Claim.—1. A valve reversing and stopping gear comprising an eccentric, an eccentric-strap surrounding the eccentric, the eccentric-strap adapted to reciprocate with relation to the guides, tracks formed on two opposite sides of the strap, guides located on two opposite sides of the eccentric-strap, the tracks adapted to be received in the guides, whereby the strap reciprocates between the guides.

2. A valve-reversing gear comprising a shaft, an eccentric on the shaft, a strap surrounding the eccentric, guides located on opposite sides of the eccentric-strap between which guides the strap is adapted to reciprocate, bars connecting the guides, the bars located outside the plane of travel of the straps, reversing-guides pivoted on the shaft outside the plane of travel of the eccentric-strap, the reversing-guides received between the bars which constitute guides therefor, and means for swinging the reversing-guides upon the shaft as a center whereby to vary the direction of reciprocation of the eccentric-strap.

3. A valve-reversing gear comprising a shaft, an eccentric rigidly secured thereon, an eccentric-strap surrounding the eccentric, eccentric-guides located on opposite sides of the strap, tracks formed upon the contiguous edges of the strap and guides, the tracks adapted to register with one another whereby the strap is permitted a reciprocatory movement between the guides and a yoke surrounding the guides and eccentric-strap, the yoke adapted to retain the members in position with relation to each other.

4. A valve-reversing gear comprising a shaft, an eccentric mounted thereon, an eccentric-strap surrounding the eccentric, guides between which the strap is received and reciprocates, a yoke surrounding the eccentric, eccentric strap and guides, a connecting-rod to which the yoke is attached, reversing-guides pivoted on the shaft, means connecting the eccentric-guides, between which the reversing-guides are received whereby the reversing-guides are enabled to change the direction of reciprocation of the eccentric-strap and means for swinging the reversing-guides.



5. A valve-reversing gear comprising a shaft, an eccentric mounted thereon, a strap surrounding the eccentric, ribs formed on opposite sides of the straps, grooved eccentric-guides between which the strap is received and is adapted to reciprocate, the ribs received in the grooves, a yoke surrounding and retaining the eccentric-guides in place, the yoke received in grooves in the guides, reversing-guides pivotally mounted on the shaft, means on the eccentric-guides between which the reversing-guides are received means for rocking the reversing-guides on the shaft whereby a partial revolution is given the eccentric-guides in the yoke, the reversing-guides adapted to regulate the direction of motion of the eccentric-strap in this manner.

6. The combination with a valve-reversing gear, of an annular yoke, a pair of oppositely-disposed segmental eccentric-guides located within the circle embraced by the yoke, a rectangular eccentric-strap located in the space between the two guides, the strap adapted to reciprocate therebetween, an eccentric, a shaft to which the eccentric is keyed, the eccentric inclosed by the eccentric-strap, a pair of reversing-guides journaled on the shaft on either side of the eccentric, means for retaining the reversing-guides in fixed relation to the eccentric-guides, a connecting-rod removably secured to the yoke, a valve, a valve-stem, the outer end of which is pivotally secured to the free end of the connecting-rod and means for rocking the reversing-guides on the shaft to reverse the admission-point of the steam and to stop the engine.

7. A valve-reversing gear comprising a shaft, an eccentric secured on the shaft, an eccentric-strap surrounding the eccentric, guides between which the strap is received and reciprocates, a yoke surrounding the guides to retain the parts in position, reversing-guides pivotally mounted on the shaft, the reversing-guides adapted to vary the direction of travel of the eccentric-strap, a connecting-rod secured to the yoke, a valve-stem pivotally secured to the rod, the movement of the valve-stem regulated by the direction of movement of the eccentric-strap whereby a greater or lesser amount of steam is admitted to the cylinder of the engine.

8. A valve-reversing gear comprising a reciprocating member, oscillating means between which the reciprocating member moves, means for varying the direction of movement of the reciprocating member, a yoke surrounding the reciprocating member and the oscillating means between which it moves, a rod secured at one end to the yoke, a valve-stem pivotally secured to the opposite end of the rod, the movement of the valve-stem regulated by the direction of movement of the reciprocating member whereby to govern the amount of power admitted by the valve on the valve-stem to the engine-cylinder.

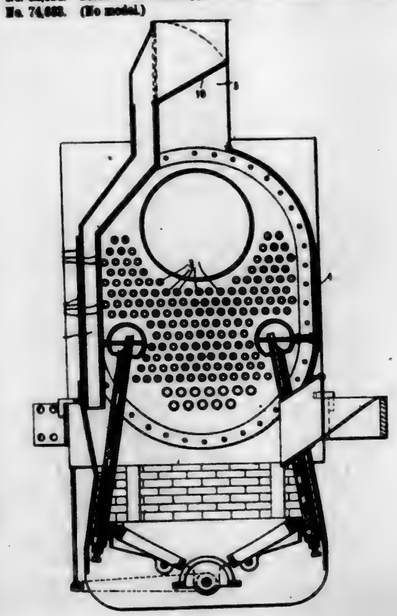
9. A valve-reversing gear comprising a shaft, an eccentric secured thereon, an eccentric-strap received upon and surrounding the eccentric, ways formed in opposite sides of the strap, segmental guides between which the strap is received and reciprocates, the segmental guides provided with grooves on their straight edges in which are received the ways on the strap, a yoke in which the segmental guides are received and inclosed, the yoke received in grooves on the arc-shaped edges of the segmental guides, reversing-guides pivotally mounted on the shaft on either side of the eccentric, bars secured to and connecting the segmental guides, the reversing-guides received between and contacting with the bars, and means whereby the reversing-guides, and segmental guides are swung in the arc of a circle to vary the direction of reciprocation of the eccentric-strap.

10. A valve-reversing gear comprising a shaft, an eccentric secured thereon, an eccentric-strap received upon and surrounding the eccentric, ways formed in opposite sides of the strap, segmental guides between which the strap is received and reciprocates, the segmental guides provided with grooves on their straight edges in which are received the ways on the strap, a yoke in which the segmental guides are received and inclosed, the yoke received in grooves on the arc-shaped edges of the segmental guides, reversing-guides pivotally mounted on the shaft on either side of the eccentric, a plurality of bars secured to each side of and connecting the segmental guides, the reversing-guides fitted between the bars, levers, rods connecting the reversing-guides and the levers whereby the reversing-guides may be moved to any angular position to swing the segmental guides in the yoke whereby to give a direct angular direction of reciprocation to the segmental guides and eccentric-strap.

11. A valve-reversing gear comprising a shaft, an eccentric secured thereon, an eccentric-strap received upon and surrounding the eccentric, eccentric segmental guides between which is received and reciprocates the eccentric-strap, the guides provided with grooves on their peripheries, a yoke seated in the grooves and inclosing the guides, bars secured to and connecting the guides, the bars located on either side of the guides, reversing-guides pivoted on the shaft and received between the bars and means for rocking the reversing-guides in the arc of a circle.

12. A valve-reversing gear comprising a shaft, an eccentric secured thereon, an eccentric-strap on the eccentric, tracks on the strap, guides with a groove formed in the periphery thereof, the strap received and reciprocating between the guides, a yoke surrounding the guides and received in the groove, and movable reversing-guides adapted to guide the travel of the eccentric-strap to maintain a direct angular travel, whereby the relative travel of the valve is the same on the direct or reverse motion.

707,996. STEAM-GENERATOR. PAUL H. WHITE, Indianapolis, Ind., assignor to White Steam Wagon Company, Indianapolis, Ind., a Corporation of Indiana. Original application filed May 27, 1901, Serial No. 62,693. Divided and this application filed Sept. 7, 1901. Serial No. 74,662. (No model.)



Claim.—1. In a steam-generator, the combination with a furnace, of a main outlet leading therefrom above the body of the generator, a supplemental outlet leading from the furnace below the body of the generator, and means for controlling the passage of heat through the outlets so that when the main outlet is closed a non-circulating heat will be maintained in the body of the generator.

2. In a steam-generator, the combination with the main body of the generator, of a furnace, an outlet leading through the main body of the generator, a supplemental outlet passing around the main body of the generator, and means arranged above the main body of the generator for controlling the passage of heat through said outlets.

3. In a steam-generator, the combination with the water-tubes thereof, of an inclosing casing, a furnace mounted beneath said tubes, a main outlet leading from said casing, a supplemental outlet passing around the water-tubes and communicating with the furnace below the water-tubes and with the main outlet above the water-tubes, and a damper arranged above the water-tubes so as to close either the supplemental outlet or the main outlet.

707,997. **NUT-CRACKER.** AUGUST WESTRUM, Denver, Colo. Filed Dec. 17, 1901. Serial No. 86,262. (No model.)

Claim.—1. In a nut-cracker, the combination with a suitable casing, of a stationary jaw, a movable jaw having a projection protruding through the casing to permit the opening of the jaw by pressure thereon, an eccentric pivoted in the casing, a lever-arm connected with the eccentric, and a rod connecting the movable jaw with the eccentric.

2. The combination with a casing, of a stationary jaw, a coöperating movable jaw, a spring normally holding the movable jaw in the closed position, the movable jaw being provided with an elongated opening, a connecting-rod having one extremity located in said opening, an eccentric to which the opposite extremity of the rod is connected, and a lever-arm for actuating the eccentric.

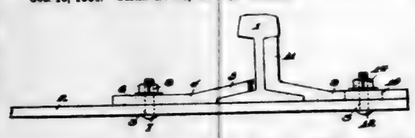
3. In a nut-cracker, the combination with a casing, of a stationary jaw, a movable jaw coöperating with the stationary jaw, a spring for holding the movable jaw in the closed position, the movable jaw having a projection protruding through the casing to permit the opening of the jaw by pressure thereon, the jaw being provided with an elongated opening, a rod having one extremity engaging said opening, and suitable means connected with the opposite extremity of the rod for actuating the movable jaw for the purpose set forth.

4. In a nut-cracker, the combination with a suitable casing, of a stationary jaw, a movable jaw coöperating with the stationary jaw, the movable jaw having a projection protruding through the casing to permit the opening of the jaw by pressure thereon, a weak spring normally holding the movable jaw in the closed position, an eccentric mounted in the casing, a rod connecting the eccentric with the movable jaw, and a lever-arm for actuating the eccentric.

707,998. **LAST.** JAMES D. WINCHESTER, Beverly, Mass. Filed Sept. 13, 1901. Serial No. 75,268. (No model.)

Claim.—A last, having two sections with diagonal surfaces slidably engaged together, for the purpose specified, one section being grooved at its inclined surface, a slotted plate arranged over the groove, the upper end of the plate being projected into a notch in said section, a fastening device extending through the lower end of the plate and into said section, and screws fastened to the other section of the last and slidably fitting in the slot of the plate, the heads of the screws being located in the groove of the first-named last-section.

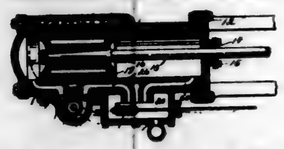
707,999. **MINE-CAR RAIL.** JOSEPH A. CRAIG, Roscoe, Pa. Filed Oct. 16, 1901. Serial No. 78,779. (No model.)



Claim.—A rail-joint comprising in combination with a chair 9 having a transverse slot 10 and an upwardly-projecting portion adapted to be held against the under face of the tread of the rail, a swinging plate 4 and retaining pivotal bolt, the free end of said plate 4 being rounded and adapted to wedge against the web of a rail as set forth.

REISSUES.

12,024. **GAS AND STEAM CONVERTIBLE ENGINE.** GUSTAVE DAHLBERG, McDonald, JACOB CROQUENOUR, Taylorstown, and ERNEST UHLER, McDonald, Pa., assignors, by direct and mesne assignments, to D. C. & U. Gas Engine Company, Washington county, Pa. Filed Aug. 7, 1901. Serial No. 71,578. Original No. 683,339, dated Sept. 19, 1899.



Claim.—1. In a convertible engine, the combination, with a cylinder, of a piston therein, a chest in communication with the cylinder, passages for steam and for an explosive mixture leading into the chest, fluid-passages from the chest to the cylinder in communication with opposite ends of the cylinder, a valve-casing provided with a valve for controlling the admission of an explosive charge to the combustion end of the cylinder said valve adapted to be opened by the pressure of the compressed explosive charge within the chest, substantially as set forth.

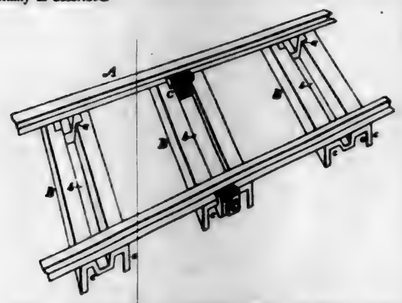
2. In a convertible engine, the combination, with a cylinder having a piston therein, of a chest in communication with the cylinder and with a steam-supply passage and an explosive-mixture passage whereby both steam and an explosive mixture are admitted to the chest at will, a mixer connected with the chest provided with means for controlling the admission of the explosive mixture to the chest, fluid-passages from the chest to opposite ends of the cylinder, a valve arranged in the passage leading to the combustion end of the cylinder for controlling the admission of a compressed explosive charge from the chest to the cylinder and adapted to be opened by the pressure of the compressed explosive charge, substantially as set forth.

12,025. **RAILROAD-TIE.** WILLIAM C. GREGG, Minneapolis, Minn., assignor to Wm. C. Gregg & Co., a Corporation of Minnesota. Filed Sept. 23, 1901. Serial No. 76,319. Original No. 684,982, dated Dec. 12, 1899.

Claim.—1. In a railroad-tie, the combination of a laterally-pierced, longitudinally grooved and flanged strip of sheet metal, upon which the rails rest and to which they are secured; a pair of jaws, one of which enters the said lateral openings, and one of which overlaps the end of the said tie, and a clamp-bolt underlying the said rail and uniting the said jaws, substantially as shown and described.

2. In a railroad-tie, the combination of the laterally-pierced and longitudinally grooved strip of sheet metal having vertically-depending flanges adapted to enter the ground, jaws adapted to enter the said laterally-pierced tie and to engage the base of the said rail, similar jaws adapted to overlap the ends of the said tie, exteriorly-threaded bolts adapted to underlie the said rails and to unite the said jaws, and interiorly-threaded nuts adapted to tighten the said jaws and to clamp the said rails, substantially as shown and described.

3. The combination with a metallic railroad-tie, longitudinally grooved and laterally pierced, and upon which the rails rest and to which they are secured, of a pair of jaws, one of which enters the lateral openings and overlaps the foot or base upon the inner side of the rail, and one of which overlaps the end of the tie and the foot or base upon the outer side of the rail, and a clamp-bolt underlying said rail and uniting said jaws, substantially as described.



4. The combination with a metallic railroad-tie, longitudinally grooved and laterally pierced, and upon which the rails rest and to which they are secured, of a pair of jaws, one of which enters the lateral openings and overlaps the foot or base upon the inner side of the rail, and one of which engages the tie and overlaps the foot or base of the rail upon its outer side, and a clamp-bolt underlying said rail and uniting said jaws, substantially as described.

12,026. **EGG-BEATER.** WILLIAM G. BROWNE, Kingston, N. Y., assignor to the W. G. Browne Manufacturing Company, a Corporation of New York. Filed Nov. 1, 1901. Serial No. 80,826. Original No. 673,456, dated July 16, 1901.

Claim.—1. In an egg-beater, a rotary beater-blade comprising a flat bowed portion and a flange projected therefrom at an angle and in a relation to the forward edge thereof whereby said forward edge constitutes a cutter-blade and an open gathering and retarding pocket is formed by the angle between the flat surface of said bowed portion and said flange, in combination with means whereby said blade is rotated.

2. In an egg-beater, a rotary beater-blade comprising a flat bowed portion and a flange projected therefrom at an angle and in a relation to the forward edge thereof whereby said forward edge constitutes a cutter-blade and an open gathering and retarding pocket is formed by the angle between said flat surface of said bowed portion and said flange, said flange being provided with a plurality of openings to permit the escape of matter gathered in said pocket in minute streams, in combination with means whereby said beater-blade is rotated.

3. In an egg-beater, the combination with a plurality of rotary beater-blades each comprising a bowed portion, and a flange projected therefrom at an angle and in a relation to the forward edge thereof, whereby said forward edge constitutes a cutter-blade and an open gathering and retarding pocket is formed by the angle between said bowed portion and said flange, said flange being provided with a plurality of openings to permit the escape of matter gathered in said pocket in minute streams, of means whereby said blades may be simultaneously and reversely rotated.

4. In an egg-beater, the combination with a plurality of eccentrically-mounted rotary beater-blades each comprised of diametrically opposite flat and parallel bowed portions and a crescent-shaped or segmental flange projected inwardly at an angle therefrom and in a relation to the forward edge thereof whereby said forward edge constitutes a cutter-blade and an open gathering and retarding pocket is formed by the angle between the flat surface of said bowed portion and said flange, said flange being provided with a plurality of openings to permit the escape of matter gathered in said pocket of means whereby said beater-blades may be simultaneously and reversely rotated.

DESIGNS.

86,022. **HANDLE FOR TOILET ARTICLES.** ROBERT B. DEMAREST, New York, N. Y. Filed May 8, 1902. Serial No. 106,690. Term of patent 14 years.

Claim.—The ornamental design for a handle for toilet articles, substantially as herein shown and described.

86,028. **BACK FOR BRUSHES OR SIMILAR ARTICLES.** SIDNEY A. KELLER, New York, N. Y. Filed July 28, 1902. Serial No. 116,744. Term of patent 3½ years.

Claim.—The ornamental design for a back for brushes, mirrors, or similar articles, substantially as herein shown and described.

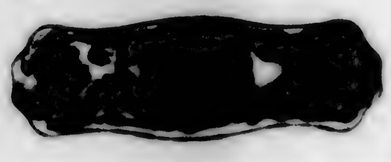
36,024. HANDLE FOR BUTTON-HOOKS OR SIMILAR ARTICLES. Ernest A. Kilian, New York, N. Y. Filed July 23, 1902. Serial No. 116,763. Term of patent 3½ years.

Claim.—The ornamental design for a handle for button-hooks or similar articles, substantially as herein shown and described.

36,025. LID FOR POST-CHECKED SIMILAR ARTICLES. Ernest A. Kilian, New York, N. Y. Filed July 23, 1902. Serial No. 116,765. Term of patent 3½ years.

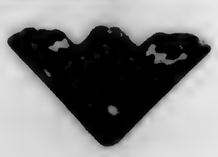
Claim.—The ornamental design for a lid for post-boxes or similar articles, substantially as herein shown and described.

36,026. BASE FOR CHECKED OR SIMILAR ARTICLES. Ernest A. Kilian, New York, N. Y. Filed July 23, 1902. Serial No. 116,766. Term of patent 3½ years.



Claim.—The ornamental design for a base for brushes, mirrors, or similar articles, substantially as herein shown and described.

36,027. CHECK FOR CHECKED OR SIMILAR ARTICLES. Ernest A. Kilian, New York, N. Y. Filed July 23, 1902. Serial No. 116,767. Term of patent 3½ years.

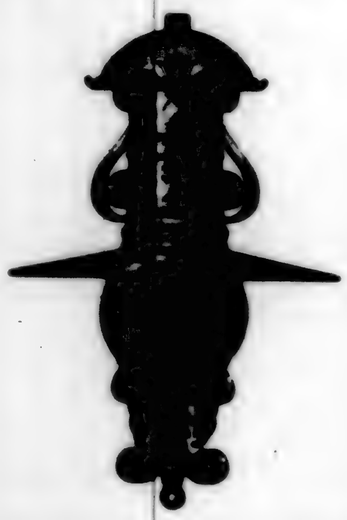


Claim.—The ornamental design for a check for checked or similar articles, substantially as herein shown and described.

36,028. STAND FOR PHOTOGRAPH-ALBUMS. Rafael Abeshaus, New York, N. Y., assignor to Isaac Abeshaus, New York, N. Y. Filed July 19, 1902. Serial No. 116,504. Term of patent 7 years.

Claim.—The ornamental design for a stand for a photograph-album as herein shown and described.

36,029. LAMP-BODY. Bruno A. Kunz, St. Louis, Mo. Filed July 1, 1902. Serial No. 114,324. Term of patent 14 years.



Claim.—The ornamental design for a lamp-body, as herein shown and described.

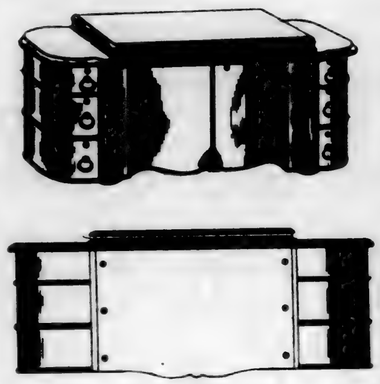
36,030. PLATE. Gustave R. Wirz, Wilkinsburg, Pa. Filed Feb 18, 1902. Serial No. 94,700. Term of patent 3½ years.

Claim.—The ornamental design for a plate, as herein shown and described.

36,031. VENDING-MACHINE CASING. Gustave W. Galvin, Rockville City, Conn. Filed May 16, 1902. Serial No. 107,031. Term of patent 7 years.

Claim.—The ornamental design for a vending-machine casing as herein shown and described.

36,032. SEWING-MACHINE TABLE. Frank G. Hoglund, Chicago, Ill., assignor to Illinois Sewing Machine Company, Chicago, Ill., a Corporation of Illinois. Filed July 1, 1902. Serial No. 114,023. Term of patent 7 years.

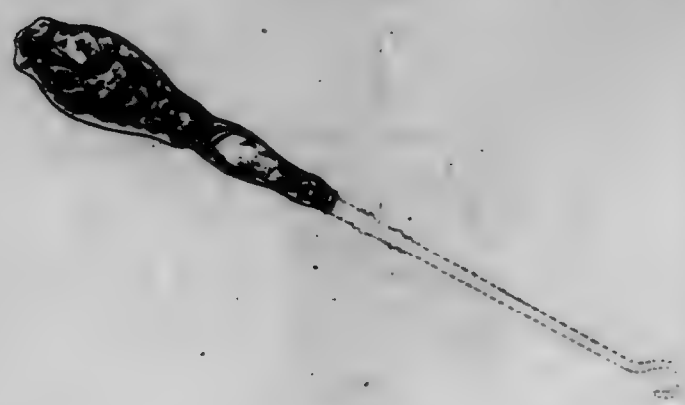


Claim.—The ornamental design for a sewing-machine table herein shown and described.

36,033. RUG. Adolph Pressla, Philadelphia, Pa., assignor to John R. Bromley and Edward Bromley, Philadelphia, Pa., copartners trading as John Bromley & Sons. Filed July 31, 1902. Serial No. 117,901. Term of patent 3½ years.

Claim.—The ornamental design for a rug, substantially as shown and described.

36,024. HANDLE FOR BUTTON-HOOKS OR SIMILAR ARTICLES. Sidney A. Keller, New York, N. Y. Filed July 22, 1902. Serial No. 116,765. Term of patent 3½ years.

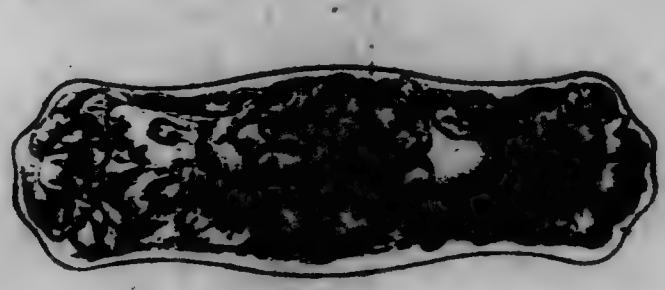


Claim.—The ornamental design for a handle for button-hooks or similar articles, substantially as herein shown and described.

36,025. LID FOR PUFF-BOXES OR SIMILAR ARTICLES. Sidney A. Keller, New York, N. Y. Filed July 22, 1902. Serial No. 116,766. Term of patent 3½ years.

Claim.—The ornamental design for a lid for puff-boxes or similar articles, substantially as herein shown and described.

36,026. BACK FOR BRUSHES OR SIMILAR ARTICLES. Sidney A. Keller, New York, N. Y. Filed July 22, 1902. Serial No. 116,768. Term of patent 3½ years.



Claim.—The ornamental design for a back for brushes, mirrors, or similar articles, substantially as herein shown and described.

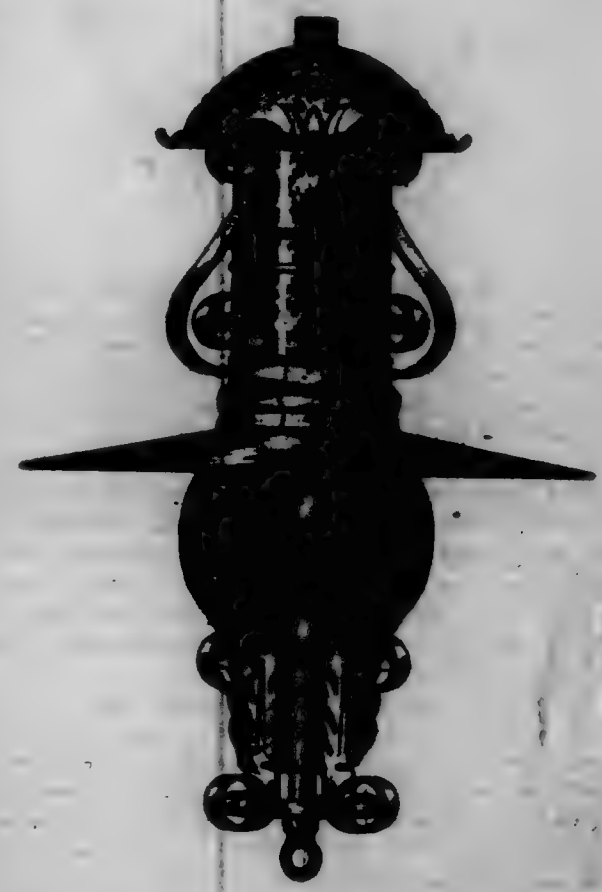
36,027. CORNER FOR BLOTTING-PADS OR SIMILAR ARTICLES. Sidney A. Keller, New York, N. Y. Filed July 22, 1902. Serial No. 116,767. Term of patent 3½ years.

Claim.—The ornamental design for a corner for blotting-pads, or similar articles, substantially as herein shown and described.

36,028. STAND FOR PHOTOGRAPH-ALBUMS. Raphael Abrahams, New York, N. Y., assignor to Rosa Abramson, New York, N. Y. Filed July 19, 1902. Serial No. 115,904. Term of patent 7 years.

Claim.—The ornamental design for a stand for a photograph-album as herein shown and described.

36,029. LAMP-BODY. Cyrus A. Kaal, St. Louis, Mo. Filed July 3, 1902. Serial No. 114,326. Term of patent 14 years.



Claim.—The ornamental design for a lamp-body, as herein shown and described.

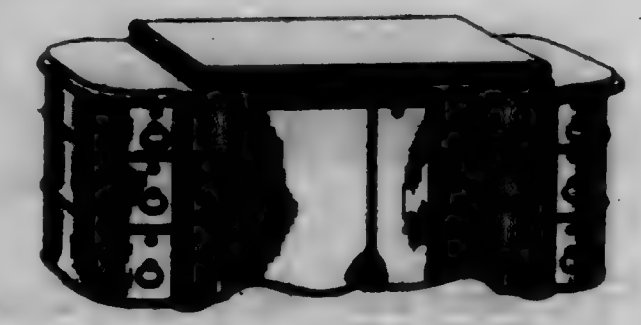
36,080. PLATE. Clement B. Wise, Williamsburg, Pa. Filed Feb. 18, 1902. Serial No. 94,702. Term of patent 3½ years.

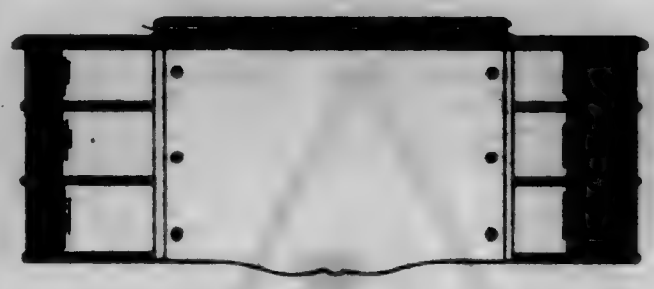
Claim.—The ornamental design for a plate, as herein shown and described.

36,081. VENDING-MACHINE CASING. Clement W. Gerrie, David City, Nebr. Filed May 16, 1902. Serial No. 107,601. Term of patent 7 years.

Claim.—The ornamental design for a vending-machine casing as herein shown and described.

36,083. SEWING-MACHINE TABLE. Frank S. Boland, Chicago, Ill., assignor to Illinois Sewing Machine Company, Chicago, Ill., a Corporation of Illinois. Filed July 1, 1902. Serial No. 114,088. Term of patent 7 years.





Claim.—The ornamental design for a sewing-machine table herein shown and described.

36,088. RUG. Adolph Pfeiffer, Philadelphia, Pa., assignor to John H. Bromley and Edward Bromley, Philadelphia, Pa., copartners trading as John Bromley & Sons. Filed July 31, 1902. Serial No. 117,261. Term of patent 3½ years.

Claim.—The ornamental design for a rug, substantially as shown and described.

TRADE-MARKS.

REGISTERED AUGUST 26, 1902.

38,881. CERTAIN NAMED PAPER. Sarason A. Jarman, New York, N. Y. Filed May 13, 1902.

The letter "J" within a diamond border. Used since April 1, 1896.

38,882. CERTAIN NAMED CLOTHING. Ezra Brevoort, St. Paul, Minn. Filed Mar. 17, 1902.

The representation of a tailor's goose or smoothing-iron, printed in red within a black border, with the words "AT THE SIGN OF THE RED GOOSE" printed in connection therewith. Used since July 1, 1900.

38,883. SYRUPS, COATS AND PANTS. John H. Woodruff, St. Louis, Mo. Filed July 8, 1902.

The word "DIAMOND" inclosed in a diamond-shaped figure. Used since January 1, 1900.

38,884. LINENS. Brown Bros. & Co., New York, N. Y. Filed May 14, 1902.

SAXON

The word "SAXON." Used since January 20, 1902.

38,885. LINENS. Brown Bros. & Co., New York, N. Y. Filed May 14, 1902.

SUNSHINE

The word "SUNSHINE." Used since May 14, 1901.

38,886. COTTON YARNS. New England Cotton Yarn Company, Jersey City, N. J., and New Bedford, Mass. Filed July 22, 1902.

The word "OVERLAND" and a circle inclosing the same. Used since July 10, 1902.

88,837. MEN'S BOOTS AND SHOES. LAMKIN & POMEROY, Boston, Mass. Filed July 5, 1902.

The word "PEDREX" and the representation of a shoe surmounted by a crown. Used since May 1, 1902.

88,888. CERTAIN NAMED BOOTS AND SHOES. DOROTHY DODD SHOE CO., Manchester, N. J., and Boston, Mass. Filed July 21, 1902.

A device comprising a shield bearing upon it two capital letters "G D" arranged facing each other, one of the letters being reversed, the shield being surmounted by a crown and deer's head. Used since May 1, 1902.

88,889. INSOLES. JOHN ARNSWALD, Sleepy Hollow, N. Y. Filed July 2, 1902.

A. H. B.

The letters "A. H. B." Used since December, 1900.

88,840. LEATHER FOR MAKING BOOTS AND SHOES. WILSON & COMPANY, Chicago, Ill. Filed July 14, 1902.

GOLDEN OAK

The words "GOLDEN OAK." Used since June, 1902.

88,841. CERTAIN NAMED PAINTS AND PAINTERS' SUPPLIES. COLONIAL WORKS, Boonton, N. J. Filed July 7, 1902.

COLONIAL

The word "COLONIAL." Used since September 1, 1897.

88,842. CERTAIN NAMED CLEANING COMPOUNDS, WOOD-STAIN, SHIP-CEMENT, AND ANTI-FOULING-BOTTOM COMPOUND. NATIONAL ARCHITECTURAL IMPROVEMENT AND SUPPLY COMPANY, Wilmington, Del., and Baltimore, Md. Filed July 19, 1902.

The representation of an ornamental base supporting two pillars, with a yoke inclosed by two concentric circles arranged behind the pillars, an eagle carrying a scroll in its beak being perched upon the outer circle, above the eagle being a star, and a transverse rectangular bar being arranged across the lower portions of the two pillars. Used since June 1, 1902.

88,848. CERTAIN NAMED CLEANING AND POLISHING PREPARATIONS. EDWARD T. EATON, Ridgewood, N. J. Filed May 31, 1902.

SILVER-ON

The hyphenated word "SILVER-ON." Used since 1894.

88,844. WHISKY AND WHISKY PREPARATIONS. The Bourmonte Co., San Francisco, Cal. Filed Nov. 25, 1901.

OLD JUDGE

The words or name "OLD JUDGE." Used since 1900.

88,845. PEPTONIZED EXTRACT OF MALT. Siegel-Cooper Co., New York, N. Y. Filed June 26, 1902.

MALT

VIGOR

The words "MALT" and "VIGOR," the latter being displayed in the form of a cross. Used since May 27, 1902.

88,846. LAGER-BEER. Duke and Brothers Canney Brewery Co., Quincy, Ill. Filed Feb. 24, 1902.

A scroll continued at its center upper and lower edges into projections in the form of a cross or fleur-de-lis, upon the scroll being the capital letter "D," and in the center of said letter "D" and on the face of the scroll being a smaller capital letter "B," the whole surrounded by heads of barley, the stems of which are crossed below the scroll. Used since June 1, 1897.

88,847. FLOUR. Geo. J. Evans, Indianapolis, Ind. Filed May 17, 1902.

E-Z-BAKE

The letters and characters "E-Z-BAKE." Used since March 5, 1902.

88,848. ARTIFICIAL FOOD DERIVED FROM ALBUMINOIDS. Aktien-Gesellschaft für Anilin-Fabrikation, Berlin, Germany. Filed Apr. 5, 1902.

Glectone.

The word "GLECTONE." Used since September 30, 1901.

88,849. ALMONDS. Bryan & Co., Malaga, Spain. Filed Dec. 3, 1901.

The representation of a saddled and bridled horse. Used since August 24, 1892.

88,850. [illegible] June 24, 1902.

88,851. [illegible] Filed [illegible]

88,852. [illegible] Warner, [illegible]

88,853. [illegible]

88,850. TABLE-SAUCE. Sconce & Walker, Toledo, Ohio. Filed June 26, 1902.

The representation of a lily and leaves and a monogram "F & Co" upon the same. Used since May 1, 1902.

88,851. LAUNDRY SOAP. The B. K. Fairbank Company, Chicago, Ill. Filed May 22, 1902.

LONE STAR

The words "LONE STAR." Used since October, 1898.

88,852. CERTAIN NAMED TOILET ARTICLES. Bella Perry Watson, London, England. Filed June 26, 1902.

SLENDERINE

The word "SLENDERINE." Used since June, 1899.

88,853. DEVICES FOR APPLYING EMBELLISHMENTS TO WOMEN'S OR CHILDREN'S. Emily Sommers, Chicago, Ill. Filed July 3, 1902.

ANTIGON

The word "ANTIGON." Used since December, 1901.

88,854. POISON FOR THE EXTERMINATION OF INSECTS AND ANIMALS. Rodney Charles Tabb, Providence, R. I. Filed June 26, 1902.

PEACHENE.

The word "PEACHENE." Used since June 18, 1902.

88,855. REMEDY FOR CERTAIN NAMED DISEASES OF CATTLE. Thomas D. Young, Media, Pa. Filed Mar. 26, 1902.

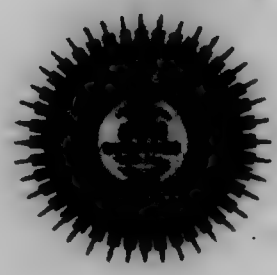
The representation of a cow on rampant hold in leash by a female attendant grasping a tether. Used since February, 1902.

88,856. CLINICAL THERMOMETERS. E. Kimmerer Optical Company, St. Louis, Mo. Filed June 26, 1902.

Household

The word "HOUSEHOLD" in script letter. Used since January 1, 1898.

88,857. HYDROCARBON-VAPOR LAMPS. The Sun Vapor Burner Lamp Co., Canton, Ohio. Filed July 3, 1902.



The words "THE SUN OUTSHINES THEM ALL," arranged within a circle formed by the conventional representation of the sun's rays. Used since 1877.

38,858. OFFBOARD LIBRARY FURNITURE. The File Maker Co., Lim., Grand Rapids, Mich. Filed Jan. 30, 1902.

A broad and curved dash, the same being oppositely curved at its respective ends or having an "ogee" curvature. Used August 1, 1895.

38,859. PNEUMATIC TOOLS. James E. Hayes, Chicago, Ill. Filed Apr. 30, 1902.

A monogram of the letters "E E H." Used since January 1, 1902.

THE SOBER-SETTERS CO.

DECISIONS

OF THE

COMMISSIONER OF PATENTS

AND OF

UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

FELBEL v. OLIVER.

Decided April 22, 1901.

1. INTERFERENCE—SUPPRESSION OF TESTIMONY—PRINTED RECORD.
Where certain testimony taken is ordered suppressed, *Held* that it should not be embodied in the printed record, since that record should contain only matter properly in the case.

2. SAME—SAME—REMOVING SUPPRESSED DEPOSITION FROM PRINTED RECORD.
Where a party prints in his record depositions which have been suppressed, *Held* that a motion to expunge, cancel, and remove it entirely from the printed record will be granted.

APPEAL on motion.

TYPE-WRITING MACHINE.

Application of Jacob Felbel filed December 18, 1899, No. 740,708. Application of Thomas Oliver filed July 17, 1899, No. 724,049.

Mr. William W. Dodge for Felbel.
Messrs. Poole & Brown for Oliver.

ALLEN, *Commissioner:*

This case is before me on an appeal by Oliver from the decision of the Examiner of Interferences granting a motion by Felbel for an order requiring Oliver to expunge, cancel, and remove entirely from Oliver's printed record the deposition of Robert H. Wiles and also to remove from the index all reference to the deposition of Wiles, together with his name appearing in the notary's certificate.

It appears from the record that on December 8, 1900, the Examiner of Interferences granted a motion by Felbel to strike out the deposition of the witness Wiles, and on January 18, 1901, his decision was affirmed by the Assistant Commissioner. Thereafter and on March 19 Oliver filed his printed record containing the deposition of Wiles in the same manner as if it had not been ordered stricken out. This was clearly contrary to the intent and purpose of the Assistant Commissioner's decision suppressing the deposition. It should not have been printed at all in the record, and Oliver himself practically admits that it should not have been printed in the same manner as the other depositions, for he says in his appeal—

> * * * in order to fully carry out the spirit and intent of the decision of the Assistant Commissioner dated Jan. 18th, 1901, the utmost that Oliver can properly be called upon to do is to plainly designate or mark in each filed copy of such printed record, the parts held proper to be stricken out under said decision of the Hon. Assistant Commissioner.

The decision of the Assistant Commissioner made the deposition of Wiles no part of the record to be considered in the further proceedings, and since the printed record should contain only matter properly forming a part of the case there was no error by the Examiner of Interferences in granting Felbel's motion. (*Dashiell* v. *Tasker*, 68 MS. Dec., 285.)

The decision of the Examiner of Interferences is affirmed.

EX PARTE THE MIAMI CLOTHING MANUFACTURING COMPANY.

Decided December 28, 1901.

1. TRADE-MARKS—DESCRIPTIVE—"FULLOUT."
"Fullout" as a trade-mark for clothing refused registration on the ground that it is descriptive, since it would convey to the purchasing public a definite idea of the style of the clothing.

2. SAME—SAME—PRINTING IN SCRIPT.
Merely printing a mark otherwise not registrable in script with a flourish beneath it does not render it registrable.

ON appeal.

TRADE-MARK FOR CLOTHING.

Application filed July 31, 1901, No. 68,890.

Mr. R. J. McCarty and *Mr. D. P. Wolhaupter* for the applicant.

ALLEN, *Commissioner:*

This is an appeal from the decision of the Examiner of Trade-Marks refusing to register for overalls and shirts a mark the essential feature of which is said to be—

> the word "Fullcut" printed in facsimile of handwriting with the heavily-shaded flourish continued from the last letter beneath the word, and the word "Brand" printed on the tail of the flourish.

The ground of refusal is that the mark is descriptive of the merchandise upon which it is used and that the style in which it is printed does not render it so arbitrary and distinctive as to entitle the applicant to its exclusive use.

There is no doubt in my mind that the word "Fullcut" would convey to the purchasing public a definite idea of the style of the clothing upon which it is used. The term "full cut" is an expression well known as applied to clothing to distinguish it from that which is close-fitting and is descriptive of this quality. No one can be adjudged to have the exclusive right to such terms of description.

Merely printing a mark otherwise not registrable in script with a flourish beneath it does not render it registrable. This is a common way of printing words and marks and is not sufficient to lend distinctiveness to a particular mark. The ex-

sential feature which is impressed upon the purchaser and upon which the mark must stand or fall is the word which is printed and not the style of the printing.

The decision of the Examiner of Trade-Marks is affirmed.

EX PARTE WOOLWORTH.

Decided December 31, 1901.

TRADE-MARKS—DESCRIPTIVE—"NEVERS-TICK."

"Nevers-Tick" as a trade-mark for lubricants refused registration upon the ground that it is descriptive.

ON appeal.

TRADE-MARK FOR LUBRICANT.

Application of Leland G. Woolworth for registration filed March 15, 1900, No. 60,767.

Mr. James J. Sheehy for the applicant.

ALLEN, *Commissioner:*

This is an appeal from the decision of the Examiner of Trade-Marks refusing to register the word "Nevers-Tick" as a trade-mark for lubricants for machinery, drawer-slides, and the like.

Sticky is the antithesis of slippery, and to say that a lubricant does not stick is to describe in an ordinary way a quality or characteristic of it. Being a lubricant, it is of course intended to be slippery and not sticky, and no one is entitled to the exclusive right to say that a lubricant sold by him does not stick or never sticks. Such descriptive words cannot be taken to indicate to the purchaser origin or ownership of the goods.

This appellant has adopted a form for writing the descriptive words which differs in some respects from the ordinary; but the differences are not sufficient to destroy the identity of the words. They would be understood when read or pronounced in the same way as if written in the ordinary manner.

The decision of the Examiner of Trade-Marks is affirmed.

EX PARTE BARRETT & BARRETT.

Decided February 5, 1902.

TRADE-MARK—"MALT MYRRH" FOR MALT LIQUORS—DESCRIPTIVE.

Held that "Malt Myrrh" as a trade-mark for malt liquors is not registrable, since the word "Malt" is clearly descriptive and "Myrrh" is either descriptive or deceptive.

ON appeal.

TRADE-MARK FOR LIQUORS, ETC.

Application for registration filed August 22, 1901, No. 64,020.

Mr. John R. Philp for the applicants.

ALLEN, *Commissioner:*

This is an appeal from the action of the Examiner of Trade-Marks refusing to register the words "Malt Myrrh" as a trade-mark for malt liquors or beverages.

The word "Malt" is undoubtedly descriptive of the goods upon which it is used, and "Myrrh" is a descriptive word which would convey the impression that the beverage contained myrrh. Since the applicant states that the beverage does not in fact contain myrrh, this word applied to it is deceptive.

Registration was properly refused for the reason that the mark is partly descriptive and partly deceptive.

The decision of the Examiner of Trade-Marks is affirmed.

EX PARTE MCNEIL.

Decided July 16, 1901.

1. PATENTABILITY—INVENTION—NEW ELEMENT OF OLD COMBINATION.

The combination of a trimmer with one type of stitch-forming mechanism being old, *Held* that it is not invention to combine that trimmer with another stitch-forming mechanism, whether the second stitch-forming mechanism be new or old, when no new result is accomplished which differs in kind from the result accomplished by the first combination and when each element acts in its own way and is not affected by the other and performs its function in the combination irrespective of the other.

2. SAME—SAME—SAME.

Held, further, that the invention, if any, is in the stitch-forming mechanism and that the applicant should claim it separately if he regards himself as the inventor of it.

APPEAL from Examiners-in-Chief.

SEWING-MACHINES.

Application of Chester McNeil filed December 31, 1897, No. 665,193.

Mr. C. L. Sturtevant for the appellant.

MOORE, *Acting Commissioner:*

This is an appeal from the decision of the Examiners-in-Chief affirming the rejection by the Primary Examiner of seventeen claims. As stated by the Examiners-in-Chief, it is only necessary to refer to one as an example.

1. In a sewing-machine, in combination with stitch-forming mechanism, including devices for forming two rows of irregular stitches, the adjacent loops of which are interlocked, of a trimmer arranged in advance of the stitch-forming mechanism and in the line of the seam, substantially as described.

Claim 5 is rejected on the ground that it covers a construction not shown and described. This claim is as follows:

5. The combination, in a sewing-machine, of a suitable trimmer, stitch-forming mechanism in rear of said trimmer including a plurality of eye-pointed thread-carrying devices forming parallel rows of stitches upon opposite sides of the line of feed and eye-pointed thread-carrying devices reciprocating back and forth between said opposite rows of stitches and forming intermediate interlocking rows of stitches, substantially as described.

The references are patents to Nichols, October 5, 1875, No. 168,521; Woodward, December 29, 1891, No. 466,264; Woodward and Timm, August 9, 1892, No. 480,377; Borton and Willcox, May 30, 1893, No. 496,616.

It is old in a sewing-machine to combine a trimmer with a stitch-forming mechanism. This combination is shown in the patent to Borton and Willcox. In this patent the trimmer is arranged in advance of the stitch-forming mechanism in the line of the seam, and said stitch-forming mechanism includes devices for forming two rows of stitches.

The particular stitch-forming mechanism shown by appellant and which constitutes an element in the combinations of his claims is not separately claimed by the appellant. Such a stitch-forming mechanism is shown, described, and claimed in the patent to Woodward.

The appellant has filed affidavits under the provisions of Rule 75 to establish a date of invention of the matter claimed prior to the date of filing of Woodward's application which resulted in the grant of his patent, No. 466,264, on December 29, 1891. The Examiner has held that these affidavits are not sufficient for the purpose. Whether they are sufficient or not is immaterial from the view I take of this case.

Borton and Willcox having invented the combination of a trimmer with a stitch-forming mechanism, it is not invention to combine a trimmer with another stitch-forming mechanism whether the stitch-forming mechanism be new or old. No new result is accomplished by appellant which differs in kind from the result accomplished by Borton and Willcox. There is no special coaction between the particular stitch-forming mechanism and the trimmer. Each acts in its own way and is not affected by the other and performs its function in the combination irrespective of the other. I think that what the appellant has done is within the province of the mechanic and does not amount to invention.

As stated by the Supreme Court of the United States in *Hill* v. *Wooster*, (50 O. G., 560)—

* * * it is not enough that a thing shall be new, in the sense that in the shape or form in which it is produced it shall not have been before known, and that it shall be useful, but it must, under the Constitution and the statute, amount to an invention or discovery.

If appellant regards himself to be the original inventor of the particular stitch-forming mechanism shown and described, he should claim it. The showing and description do not warrant the allowance of claim 5. I can find no description of "eye-pointed thread-carrying devices reciprocating back and forth" between the opposite rows of stitches, which mechanism is specified in said claim.

The decision of the Examiners-in-Chief is affirmed.

DECISIONS OF THE U. S. COURTS.

Court of Appeals of the District of Columbia.

IN RE FRASCH.

Decided June 23, 1902.

1. APPEAL—JURISDICTION—DIVISION OF APPLICATION.

An appeal from the decision of the Commissioner of Patents requiring division between process and apparatus dismissed for want of jurisdiction.

2. SAME—DIVISION—INTERLOCUTORY ORDER.

The requirement for division is not a refusal of a patent, but is a mere interlocutory order from which there can be no appeal.

3. SAME—REFUSAL OF PATENT—FINAL ORDER NECESSARY.

The right to appeal to the Court of Appeals of the District of Columbia from a decision of the Commissioner of Patents is limited to two classes of cases: first, where an application for patent has been finally denied, and, second, where in an interference proceeding there has been a final determination of the question of priority of invention between adverse claimants.

Mr. Charles J. Hedrick for the appellant.

Mr. John M. Coit for the Commissioner of Patents.

SHEPARD, *J.:*

The proceeding in this case began with an application by Herman Frasch, filed November 18, 1899, for a patent for a process and apparatus for removing incrustation of calcium sulfate from brine-heating surfaces.

The application concludes with six claims, the first three of which are for the process, and the last three for a particular apparatus to be used in the application of the process.

The Primary Examiner, on December 16, 1899, notified the applicant that his specifications and claims presented two different subjects of invention, namely, process and apparatus, and, calling his attention to Rule 41 requiring division in such cases, stated that—

division on this line must be made before action upon the merits can be given.

Rule 41 reads as follows:

41. Two or more independent inventions cannot be claimed in one application; but where several distinct inventions are dependent upon each other and mutually contribute to produce a single result they may be claimed in one application.

Claims for a machine and its product must be presented in separate applications.

Claims for a machine and the process in the performance of which the machine is used must be presented in separate applications.

Claims for a process and its product may be presented in the same application.

After hearing argument on behalf of the appellant, the Examiner repeated the order for division, and notified the applicant that there was no appeal because there had been no rejection of his application. He therefore declined to transmit the case to the Examiners-in-Chief as appealed from his decision, and called applicant's attention to his right of petition to the Commissioner of Patents under Rule 145, which authorizes the review by the Commissioner of any repeated ruling of an Examiner—

which does not involve the merits of the invention claimed, or the rejection of a claim.

On December 19, 1901, applicant presented a petition to the Commissioner in which he recited the proceedings in the Office and the rulings of the Examiner and prayed relief.

On January 23, 1902, the Commissioner rendered the following decision upon this petition:

This is a petition from the action of the Primary Examiner requiring division in the above-entitled case and refusing to forward to the Examiners-in-Chief an appeal which has been filed.

The application includes claims to a process and claims to an apparatus, and therefore the Examiner properly required division and refused to act upon the merits of the claims until that requirement was complied with. The petitioner regarded this as a refusal of a patent to him and filed a request for reconsideration, which he calls a persistence in his claim, under section 4909 of the Revised Statutes, and upon a repetition of the requirement for division filed an appeal to the Examiners-in-Chief.

A requirement for division is not an action upon the merits of the application, but is a mere matter of form, and therefore a party has no right to appeal to the Examiners-in-Chief from such a requirement. It is not a refusal of a patent or patents upon the alleged invention or inventions, but is a ruling that the application therefor has not been made in proper form. The requirement of division may be and often is made where all of the claims are admitted to be patentable. The objection is to the way in which the matter is presented and not to the matter itself. The Examiner was right in refusing to forward the appeal. The petition is denied.

From that decision the appeal has been prosecuted. On behalf of the Commissioner, a motion has been entered to dismiss for want of jurisdiction in this court to entertain the appeal.

The motion to dismiss the appeal must be granted. The right to appeal to this court from a de-

essential feature which is impressed upon the purchaser and upon which the mark must stand or fall is the word which is printed and not the style of the printing.

The decision of the Examiner of Trade-Marks is affirmed.

EX PARTE WOOLWORTH.

Decided December 31, 1901.

TRADE-NAME—REGISTRATION—"NEVER-TICK."

"Never-Tick" as a trade-mark for lubricants refused registration upon the ground that it is descriptive.

ON appeal.

TRADE-NAME FOR LUBRICANTS.

Application of Leland G. Woolworth for registration filed March 14, 1901, No. 69,767.

Mr. James J. Hinchey for the applicant.

ALLEN, *Commissioner:*

This is an appeal from the decision of the Examiner of Trade-Marks refusing to register the word "Never-Tick" as a trade-mark for lubricants for machinery, drawer-slides, and the like.

Sticky is the antithesis of slippery, and to say that a lubricant does not stick is to describe in an ordinary way a quality or characteristic of it. Being a lubricant, it is of course intended to be slippery and not sticky, and no one is entitled to the exclusive right to say that a lubricant sold by him does not stick or never sticks. Such descriptive words cannot be taken to indicate to the purchaser origin or ownership of the goods.

This appellant has adopted a form for writing the descriptive words which differs in some respects from the ordinary; but the differences are not sufficient to destroy the identity of the words. They would be understood when read or pronounced in the same way as if written in the ordinary manner.

The decision of the Examiner of Trade-Marks is affirmed.

EX PARTE BARRETT & BARRETT.

Decided February 5, 1902.

TRADE-MARK—"MALT MYRRH" FOR MALT LIQUORS—DESCRIPTIVE.

Held that "Malt Myrrh" as a trade-mark for malt liquors is not registrable, since the word "Malt" is clearly descriptive and "Myrrh" is either descriptive or deceptive.

ON appeal.

TRADE-MARK FOR LIQUORS, ETC.

Application for registration filed August 22, 1901, No. 64,030.

Mr. John R. Philp for the applicants.

ALLEN, *Commissioner:*

This is an appeal from the action of the Examiner of Trade-Marks refusing to register the words "Malt Myrrh" as a trade-mark for malt liquors or beverages.

The word "Malt" is undoubtedly descriptive of the goods upon which it is used, and "Myrrh" is a descriptive word which would convey the impression that the beverage contained myrrh. Since the applicant states that the beverage does not in fact contain myrrh, this word applied to it is deceptive.

Registration was properly refused for the reason that the mark is partly descriptive and partly deceptive.

The decision of the Examiner of Trade-Marks is affirmed.

EX PARTE MCNEIL.

Decided July 16, 1901.

1. PATENTABILITY—INVENTION—NEW ELEMENT OF OLD COMBINATION.

The combination of a trimmer with one type of stitch-forming mechanism being old, *Held* that it is not invention to combine that trimmer with another stitch-forming mechanism, whether the second stitch-forming mechanism be new or old, when no new result is accomplished which differs in kind from the result accomplished by the first combination and when each element acts in its own way and is not affected by the other and performs its function in the combination irrespective of the other.

2. SAME—SAME—SAME.

Held, further, that the invention, if any, is in the stitch-forming mechanism and that the applicant should claim it separately if he regards himself as the inventor of it.

APPEAL from Examiners-in-Chief.

SEWING-MACHINES.

Application of Chester McNeil filed December 21, 1897, No. 663,198.

Mr. C. L. Shurtcomb for the appellant.

MOORE, *Acting Commissioner:*

This is an appeal from the decision of the Examiners-in-Chief affirming the rejection by the Primary Examiner of seventeen claims. As stated by the Examiners-in-Chief, it is only necessary to refer to one as an example.

1. In a sewing-machine, in combination with stitch-forming mechanism, including devices for forming two rows of irregular stitches, the adjacent loops of which are interlocked, of a trimmer arranged in advance of the stitch-forming mechanism and in the line of the seam, substantially as described.

Claim 5 is rejected on the ground that it covers a construction not shown and described. This claim is as follows:

5. The combination, in a sewing-machine, of a suitable trimmer, stitch-forming mechanism in rear of said trimmer including a plurality of eye-pointed thread-carrying devices forming parallel rows of stitches upon opposite sides of the line of feed and eye-pointed thread-carrying devices reciprocating back and forth between said opposite rows of stitches and forming intermediate interlocking rows of stitches, substantially as described.

The references are patents to Nichols, October 5, 1875, No. 168,821; Woodward, December 28, 1891, No. 464,264; Woodward and Timm, August 9, 1892, No. 480,377; Borton and Willcox, May 30, 1893, No. 498,616.

It is old in a sewing-machine to combine a trimmer with a stitch-forming mechanism. This combination is shown in the patent to Borton and Willcox. In this patent the trimmer is arranged in advance of the stitch-forming mechanism in the line of the seam, and said stitch-forming mechanism includes devices for forming two rows of stitches.

The particular stitch-forming mechanism shown by appellant and which constitutes an element in the combinations of his claims is not separately claimed by the appellant. Such a stitch-forming mechanism is shown, described, and claimed in the patent to Woodward.

The appellant has filed affidavits under the provisions of Rule 75 to establish a date of invention of the matter claimed prior to the date of filing of Woodward's application which resulted in the grant of his patent, No. 464,264, on December 29, 1891. The Examiner has held that these affidavits are not sufficient for the purpose. Whether they are sufficient or not is immaterial from the view I take of this case.

Borton and Willcox having invented the combination of a trimmer with a stitch-forming mechanism, it is not invention to combine a trimmer with another stitch-forming mechanism whether the stitch-forming mechanism be new or old. No new result is accomplished by appellant which differs in kind from the result accomplished by Borton and Willcox. There is no special coaction between the particular stitch-forming mechanism and the trimmer. Each acts in its own way and is not affected by the other and performs its function in the combination irrespective of the other. I think that what the appellant has done is within the province of the mechanic and does not amount to invention.

As stated by the Supreme Court of the United States in *Hill* v. *Wooster*, (30 O. G., 880)—

• • • it is not enough that a thing shall be new, in the sense that in the shape or form in which it is produced it shall not have been before known, and that it shall be useful, but it must, under the Constitution and the statute, amount to an invention or discovery.

If appellant regards himself to be the original inventor of the particular stitch-forming mechanism shown and described, he should claim it. The showing and description do not warrant the allowance of claim 5. I can find no description of "eye-pointed thread-carrying devices reciprocating back and forth" between the opposite rows of stitches, which mechanism is specified in said claim.

The decision of the Examiners-in-Chief is affirmed.

DECISIONS OF THE U. S. COURTS.

Court of Appeals of the District of Columbia.

IN RE FRASCH.

Decided June 26, 1902.

1. APPEAL—JURISDICTION—DIVISION OF APPLICATION.

An appeal from the decision of the Commissioner of Patents requiring division between process and apparatus dismissed for want of jurisdiction.

2. SAME—DIVISION—INTERLOCUTORY ORDER.

The requirement for division is not a refusal of a patent, but is a mere interlocutory order from which there can be no appeal.

3. SAME—REFUSAL OF PATENT—FINAL ORDER NECESSARY.

The right to appeal to the Court of Appeals of the District of Columbia from a decision of the Commissioner of Patents is limited to two classes of cases: first, where an application for patent has been finally denied, and, second, where in an interference proceeding there has been a final determination of the question of priority of invention between adverse claimants.

Mr. Charles J. Hedrick for the appellant.

Mr. John M. Coit for the Commissioner of Patents.

SHEPARD, *J.:*

The proceeding in this case began with an application by Herman Frasch, filed November 13, 1899, for a patent for a process and apparatus for removing incrustation of calcium sulfate from brine-heating surfaces.

The application concludes with six claims, the first three of which are for the process, and the last three for a particular apparatus to be used in the application of the process.

The Primary Examiner, on December 16, 1899, notified the applicant that his specifications and claims presented two different subjects of invention, namely, process and apparatus, and, calling his attention to Rule 41 requiring division in such cases, stated that—

division on this line must be made before action upon the merits can be given.

Rule 41 reads as follows:

41. Two or more independent inventions cannot be claimed in one application; but where several distinct inventions are dependent upon each other and mutually contribute to produce a single result they may be claimed in one application.

Claims for a machine and its product must be presented in separate applications.

Claims for a machine and the process in the performance of which the machine is used must be presented in separate applications.

Claims for a process and its product may be presented in the same application.

After hearing argument on behalf of the appellant, the Examiner repeated the order for division, and notified the applicant that there was no appeal because there had been no rejection of his application. He therefore declined to transmit the case to the Examiners-in-Chief as appealed from his decision, and called applicant's attention to his right of petition to the Commissioner of Patents under Rule 145, which authorizes the review by the Commissioner of any repeated ruling of an Examiner—

which does not involve the merits of the invention claimed, or the rejection of a claim.

On December 19, 1901, applicant presented a petition to the Commissioner in which he recited the proceedings in the Office and the rulings of the Examiner and prayed relief.

On January 23, 1902, the Commissioner rendered the following decision upon this petition:

This is a petition from the action of the Primary Examiner requiring division in the above-entitled case and refusing to forward to the Examiners-in-Chief an appeal which has been filed.

The application includes claims to a process and claims to an apparatus, and therefore the Examiner properly required division and refused to act upon the merits of the claims until that requirement was complied with. The petitioner regarded this as a refusal of a patent to him and filed a request for reconsideration, which he calls a persistence in his claim, under section 4908 of the Revised Statutes, and upon a repetition of the requirement for division filed an appeal to the Examiners-in-Chief.

A requirement for division is not an action upon the merits of the application, but is a mere matter of form, and therefore a party has no right to appeal to the Examiners-in-Chief from such a requirement. It is not a refusal of a patent or patents upon the alleged invention or inventions, but is a ruling that the application therefor has not been made in proper form. The requirement of division may be and often is made where all of the claims are admitted to be patentable. The objection is to the way in which the matter is presented and not to the matter itself. The Examiner was right in refusing to forward the appeal. The petition is denied.

From that decision the appeal has been prosecuted. On behalf of the Commissioner, a motion has been entered to dismiss for want of jurisdiction in this court to entertain the appeal.

The motion to dismiss the appeal must be granted. The right to appeal to this court from a de-

cision of the Commissioner of Patents is limited to two classes of cases: first, where an application for patent has been finally denied; and, second, where, in an interference proceeding, there has been a final determination of the question of priority of invention between adverse claimants. (R. S., secs. 4911, 4912, 4918, 4914; R. S. D. C., sec. 780; act creating Court of Appeals, D. C.: approved February 9, 1893, sec. 9.)

There has been no denial of the application in this case. Its merits have not been considered. The Examiner has declined to pass upon the application or to consider the allowance of the claims, because, in his opinion, he is bound by the terms of Rule 41 to demand a division of the application; that is to say, a separate application each for the process and for the apparatus embraced in the claims of the pending application. On petition against this ruling, the Examiner has been sustained by the Commissioner. It is a mere interlocutory order from which, in either class of cases, there can be no appeal, for reasons which have been heretofore stated, and need not be repeated. (*Westinghouse* v. *Duncan*, 2 App. D. C., 131, 134.) Moreover, upon appeal from a final decision on the merits, it has been held that—

the rulings on questions of mere practice in the Patent Office will not be reviewed in this court, unless it appear that there has been an abuse in the exercise of discretion, and that substantial rights have been thereby affected or denied. (*In re Marschutz*, 18 App. D. C., 288, 286; *in re Neill*, 11 App. D. C., 564, 588.)

The contention of the appellant is, that Rule 41 is inconsistent with the statutes providing for the grant of Letters Patent, and, therefore, beyond the power of the Commissioner of Patents to enact; wherefore its enforcement in this case has worked a practical denial of the application. That such is the substantial or necessary result of the ruling we cannot agree. We do not mean to say that there may not be a way in which the power to enact Rule 41 might be brought in question as necessarily involving the denial of a substantial right under the law.

If there be such a way, however, it has not been pursued in this proceeding. Whether the power exists presents a question of great importance, both to applicants for patents and to the Government, if for no other reason than the doubling of fees which must necessarily result from its strict enforcement. Nevertheless, the question is one of practice, and to be determined by this court must come up, not on appeal from an interlocutory order for the enforcement of the rule, but as necessarily involved in a final decision of the Commissioner rejecting an application for a patent, as intimated in the cases last-above cited.

Without intending to intimate any view in respect of the authority for, or the expediency of the purpose of, the enactment of Rule 41 by the Commissioner, it may be of some interest to briefly state its history.

The rule, as it now reads, was adopted by Mr. Commissioner Duell July 18, 1899. The change consisted in adding to the rule as it then read, the three last paragraphs which require separate applications for claims for a machine and its product, for a machine and the process in the performance of which it is used, and a single application for a process and its product.

Under the general terms of the old Rule 41, the practice of the Patent Office had varied from time to time under different administrations, and fallen into some confusion as claimed by Mr. Commissioner Duell in a decision wherein he set forth the reasons inducing him to amend the rule in the particulars noted. (*Ex parte Boucher*, 88 O. G., 545; C. D., 1899, p. 133, decided July 11, 1899.)

In that opinion he referred to the decision of the Supreme Court of the United States which recognized the general discretion committed to the head of the Patent Office in the matter of the division of applications (*Bennett* v. *Fowler*, 8 Wall., 445), as well as to the manner in which that discretion had been exercised by many preceding Commissioners.

In a later case he considered the subject again, at length, in justifying the amendment that had been made. (*Ex parte Frasch*, 91 O. G., 459; C. D., 1900, p. 50.)

In that opinion he cited several decisions of the Supreme Court of the United States, as sustaining his view that a process and an apparatus to be used in its application, are separate and distinct inventions.

Without pursuing the subject further, the appeal will be dismissed without prejudice, for the reasons given; and this decision and the proceedings herein will be certified to the Commissioner of Patents as required by law. It is so ordered.

Indexes to Patents on Electricity.

Indexes to patents relating to electricity, covering the period of time from July 1, 1882, to June 30, 1896, have been issued, and are for sale. These indexes, arranged alphabetically, numerically, and by classes, comprise the following volumes, the prices of which are given below:

Vol. 1. Index to patents relating to electricity granted by the United States prior to June 30, 1881, with an appendix, July 1, 1881, to June 30, 1882. One volume, 350 pages. In paper covers, $3; bound, $5.

Vol. 2. Appendix No. 2, July 1, 1882, to June 30, 1883. One volume, 50 pages. In paper covers, $1.50.

Vol. 3. Appendix No. 3, July 1, 1883, to June 30, 1884. One volume, 60 pages. In paper covers, $1.50.

Vol. 4. Appendix No. 4, July 1, 1884, to June 30, 1885. One volume, 60 pages. In paper covers, $1.50.

Vol. 5. Appendix No. 5, July 1, 1885, to June 30, 1886. One volume, 54 pages. In paper covers, $1.50.

Vol. 6. Appendix No. 6, July 1, 1886, to June 30, 1887. One volume, 58 pages. In paper covers, $1.50.

Vol. 7. Appendix No. 7, July 1, 1887, to June 30, 1888. One volume, 66 pages. In paper covers, $1.50.

Vol. 8. Appendix No. 8, July 1, 1888, to June 30, 1889. One volume, 72 pages. In paper covers, $1.50.

Vol. 9. Appendix No. 9, July 1, 1889, to June 30, 1890. One volume, 84 pages. In paper covers, $1.50.

Vol. 10. Appendix No. 10, July 1, 1890, to June 30, 1891. One volume, 98 pages. In paper covers, $1.50.

Vol. 11. Appendix No. 11, July 1, 1891, to June 30, 1892. One volume, 86 pages. In paper covers, $1.50.

Vol. 12. Appendix No. 12, July 1, 1892, to June 30, 1893. One volume, 80 pages. In paper covers, $1.50.

Vol. 13. Appendix No. 13, July 1, 1893, to June 30, 1894. One volume, 70pages. In paper covers, $1.50.

Vol. 14. Appendix No. 14, July 1, 1894, to June 30, 1895. One volume, 68 pages. In paper covers, $1.50.

Vol. 15. Appendix No. 15, July 1, 1895, to June 30, 1896. One volume, 68 pages. In paper covers, $1.50.

Amendments to Allowed Applications.

Hereafter all amendments proposed to allowed applications and all petitions and requests relating thereto shall be filed with the docket clerk, Mr. J. M. Fowler, and transmitted by him to the Primary Examiner for report. If the Examiner shall report favorably to the admission of such amendment, the matter will be laid before the Commissioner for immediate determination. If the Examiner shall report unfavorably, the case will be docketed and will be heard and decided by the Commissioner in regular course, unless good reasons shall appear for immediate action. (Order 629 amended October 15, 1896.)

Renewal of Forfeited Applications.

Attention is called to section 4,897, Revised Statutes, relating to the renewal of allowed applications forfeited through failure to pay the final fee within six months from the date of allowance. The law requires the petition for renewal to be signed by the *inventor, discoverer*, or *assignee* and that the same be filed in this Office within two years after the allowance of the original application. If the inventor be dead, the petition must be signed by the administrator or executor; if insane, by the guardian, conservator, or legal representative. *It will not be accepted if signed by the attorney.* (Form 12, page 64, Rules of Practice, should be used.)

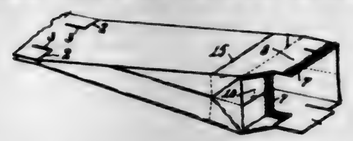
PATENTS

GRANTED SEPTEMBER 2, 1902.

708,000. POLISHING-STRIP. CHARLES C. ALLEN, Kansas City, Mo. Filed Dec. 11, 1901. Serial No. 85,497. (No model.)

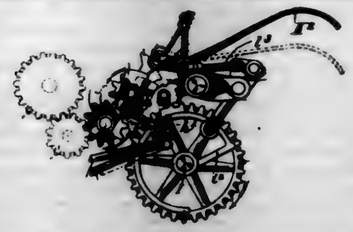
Claim.—A long and narrow flexible polishing-strip, having its side edges substantially parallel and having one of its sides partially abrasive and partially smooth; the smooth portion occurring at opposite ends of the abrasive portion.

708,001. ART OF MAKING PAPER BAGS. DANIEL APPEL, Cleveland, Ohio, assignor to the Union Paper Bag Machine Company, Philadelphia, Pa. Filed Dec. 26, 1901. Serial No. 87,173. (No model.)



Claim.—That improvement in the art of producing paper bags from a flattened pleated paper tube which consists in cross-cutting through all of the plies of the flattened pleated tube upon the opposite edges of the tube and inward to a distance less than the inward projection of the side folds of the tube, longitudinally cutting the face-plies only of the tube at right angles rearwardly from the extremities of the cross-cuts in these plies, expanding the tube to rectangular form, completing the severance at the sides of the tube, applying paste where adhesion of folds is to occur, turning the advancing portion of the side plies inwardly and rearwardly while the unsevered portions of the tube are under tension, collapsing the tube end and folded parts while under tension, relieving the tension on the folded parts and completing the severance so as to leave the tails of the face-plies free, folding one of the tails of the face-plies against the previously-inturned side plies, folding the second face-ply against the first one to complete the forming and sealing of the bag-bottom, and folding and pressing the completed bottom against the collapsed body part of the bag.

708,002. AUTOMATIC GRAIN-BINDER. JOHN F. APPLEBY, Chicago, Ill. Filed Sept. 11, 1901. Serial No. 74,807. (No model.)



Claim.—1. In an automatic grain-binder, the combination with a binding mechanism and a packing mechanism, of a continuously-rotating driving-shaft, intermittently-rotating binder-shaft and packer-shaft, gears mounted upon said driving-shaft, binder-shaft and packer-shaft, intermediate gears movably mounted, means, actuated by the packing mechanism, for moving one of said intermediate gears into position to transmit rotary motion from said driving-shaft to said binder-shaft, and also means, controlled by the binding mechanism, for moving another of said intermediate gears into position to transmit rotary motion from said driving-shaft to said packer-shaft, whereby the binding mechanism and packing mechanism are caused to intermit alternately in their operation, substantially as described.

2. In an automatic grain-binder, the combination with a binding mechanism and a packing mechanism, of a continuously-rotating driving-shaft having a gear thereon, an intermittently-rotating binder-shaft having also a gear thereon, an intermediate gear in constant mesh with the gear on said driving-shaft, means, actuated by the packing mechanism, for moving said intermediate gear into mesh and means for moving it out of mesh with the gear on said binder-shaft, an intermittently-rotating packer-shaft having a gear thereon, a second intermediate gear in constant mesh with the gear on said driving-shaft, and also means, controlled by the binding mechanism, for moving said second intermediate gear into and out of mesh with the gear on said packer-shaft, whereby the binding mechanism and the packing mechanism are caused to intermit alternately in their operation, substantially as described.

3. In an automatic grain-binder, the combination with a binding mechanism and a packing mechanism of a continuously-rotating driving-shaft having a spur-gear secured thereto, an intermittently-rotating binder-shaft having also a spur-gear secured thereto, an intermediate spur-gear in constant mesh with the gear secured to said driving-shaft, a vibrating trip-arm on which the said intermediate gear is mounted, the axis of which is concentric with said driving-shaft, packer, means, actuated by said packers, for moving said trip-arm on its axis and thereby carrying said intermediate gear mounted thereon into mesh and means, actuated by the binding mechanism, for carrying it out of mesh with the gear on said binder-shaft, an intermittently-rotating packer-shaft having a spur-gear secured thereto, a second intermediate spur-gear in constant mesh with the gear on said driving-shaft, a vibrating hanger in which the said second intermediate gear is mounted, the axis of which is concentric with said driving-shaft, an oscillating needle, and means, controlled thereby, for moving said vibrating hanger on its axis and thereby carrying the intermediate gear mounted therein into and out of mesh with the gear on said binder-shaft, whereby the binding mechanism and the packing mechanism are caused to intermit alternately in their operations, substantially as described.

4. In an automatic grain-binder, the combination with a binding mechanism and a packing mechanism, of a continuously-rotating driving-shaft, an intermittently-rotating binder-shaft, gears mounted upon said driving-shaft and binder-shaft, an intermediate gear movably mounted, means, actuated by the packing mechanism, for moving said intermediate gear into position to transmit rotary motion from said driving-shaft to said binder-shaft, whereby intermittent rotation is imparted to the binding mechanism, substantially as described.

5. In an automatic grain-binder, the combination with a binding mechanism and a packing mechanism, of a continuously-rotating driving-shaft having a gear thereon, an intermittently-rotating binder-shaft having also a gear thereon, an intermediate gear in constant mesh with the gear on said driving-shaft, means, actuated by the packing mechanism, for moving said intermediate gear into mesh and means for moving it out of mesh with the gear on said binder-shaft, whereby intermittent rotation is imparted to the binding mechanism, substantially as described.

6. In an automatic grain-binder, the combination with a binding mechanism and a packing mechanism, of a continuously-rotating driving-shaft having a spur-gear secured thereto, an intermittently-rotating binder-shaft having also a spur-gear secured thereto, an intermediate spur-gear in constant mesh with the gear secured to said driving-shaft, a vibrating trip-arm on which the said intermediate gear is mounted, the axis of

which is concentric with said driving-shaft, pawlcrum, means, actuated by said pawlcrum, for moving said trip-arm on its axis and thereby carrying said intermediate gear mounted thereon into mesh and means, actuated by the binding mechanism, for carrying it out of mesh with said gear on said binder-shaft, substantially as described.

7. In an automatic grain-binder, the combination with the binding mechanism of a constantly-rotating driving-shaft having a gear thereon, an intermittently-rotating binder-shaft having also a gear thereon, an intermediate gear in constant mesh with the gear on said driving-shaft, a vibrating trip-arm on which said intermediate gear is mounted, the axis of which is concentric with said driving-shaft, a trip-step adapted normally to engage said trip-arm, means for holding it in engagement therewith, pawlcrum, means actuated by said pawlcrum, through the instrumentality of the accumulating intervening bundle, for disengaging said trip-step from said trip-arm, links connecting said pawlcrum with said trip-arm adapted, through the action of said pawlcrum upon the accumulated grain, to move said trip-arm upon its axis and thereby carry said intermediate gear mounted thereon into mesh with the gear on said binder-shaft, and a mutilation on the gear on said binder-shaft adapted to engage said intermediate gear and move it out of mesh therewith, whereby intermittent rotation is imparted to the binding mechanism, substantially as described.

8. In an automatic grain-binder, the combination with the binding mechanism of a constantly-rotating driving-shaft having a spur-gear secured thereto, an intermittently-rotating binder-shaft having also a spur-gear secured thereto, an intermediate spur-gear in constant mesh with the gear secured to said driving-shaft, a vibrating trip-arm on which said intermediate gear is mounted, the axis of which is concentric with said driving-shaft, a trip-step adapted normally to engage said trip-arm, pawlcrum, means, actuated by said pawlcrum, through the instrumentality of the accumulating intervening bundle, for disengaging said trip-step from said trip-arm, a pivoted pawlcrum-link support, links connecting said pawlcrum with said pivoted support, a link connecting said pivoted support with said trip-arm adapted, through the action of said pawlcrum upon the accumulated grain, to move said trip-arm upon its axis and thereby carry said intermediate gear mounted thereon into mesh with the gear on said binder-shaft, and a mutilation on the gear on said binder-shaft adapted to engage said intermediate gear and move it out of mesh therewith, whereby intermittent rotation is imparted to the binding mechanism, substantially as described.

9. In an automatic grain-binder, in combination with an intermittently-rotating binder-shaft and an oscillating needle actuated thereby, means connecting said binder-shaft and needle, whereby the oscillation of said needle may be adjusted at one extremity only thereof, substantially as described.

10. In an automatic grain-binder, in combination with an intermittently-rotating binder-shaft having a crank secured thereto and an oscillating needle, a bell-crank pivoted to the needle-arm, adjustable means for holding it normally rigid therewith, and a pitman connecting the crank on said binder-shaft with said bell-crank on the needle-arm, whereby the oscillation of said needle may be adjusted at one extremity thereof, substantially as described.

11. In an automatic grain-binder, in combination with an intermittently-rotating binder-shaft having a crank secured thereto and an oscillating needle, a bell-crank pivoted to the needle-arm, a bolt pivoted in said bell-crank provided with look-nuts adapted to engage a lug on said needle, and a pitman connecting the crank on said binder-shaft with said bell-crank on the needle-arm, whereby said needle may be adjusted relative to the knotter without changing its relation to the deck, substantially as described.

708,003. PROCESS OF PRODUCING A COMPOSITION OF MATTER TO BE USED AS A SUBSTITUTE FOR RUBBER. OTTO A. BAILER, Philadelphia, Pa. Filed Dec. 27, 1901. Serial No. 87,473. (No specimens.)

Claim.—The above-described process of producing a rubber substitute by forming a solution by mixing gum-arabic, rubber dissolved in benzin, whiting and sulfur, in the proportions substantially of ten per cent. of gum-arabic, twenty per cent. of rubber, twenty-five per cent. of whiting and forty-five per cent. of sulfur, adding feathers to the above solution in the proportion of three parts by weight of feathers to one part of the solution, cooldrying the whole, pressing into the desired form and vulcanizing, substantially as and in the manner described.

708,004. MOUNTING FOR WHIFFLETREES. EDWIN W. H. BAILEY, Amesbury, Mass. Filed Oct. 10, 1901. Serial No. 78,516. (No model.)

Claim.—1. The combination with a pair of members comprising a whiffletree and its support, of an interposed plate secured to each, and a bolt serving to prevent the separation of the members passing through the plates and support and provided with means for preventing its rotation engaging said support, which means is free from such engagement with the plates and whiffletree.

2. The combination with a whiffletree and its support, of an interposed plate secured to each and having a circular opening, and a bolt passing through the openings in the plates and being provided with a squared portion of less transverse dimension than the circular openings for engaging the support.

3. The combination with a pair of members comprising a whiffletree and its support, of an interposed plate provided with a recess and having its opposite outer faces each in close proximity to one of the members and being secured to one of them, a second plate secured to the other member and located within the recess in the first plate, and a bolt passing through the plates and the support and having means for preventing its rotation engaging said support, which means is free from such engagement with the plates and whiffletree.

4. The combination with a pair of members comprising a whiffletree and its support, of an interposed plate provided with a sharpened projection adapted to be forced into engagement with one of the members, means for securing the plate to said member, and a bolt passing through the plate and at least one of the members.

5. The combination with a pair of members comprising a whiffletree and its support, of an interposed plate provided with a central opening and a reduced or sharpened projection surrounding said opening adapted to engage one of the members, means for securing the plate to said member, and a bolt passing through the opening in the plate and at least one of the members.

6. The combination with a pair of members comprising a whiffletree and its support, of a plate secured to one of the members provided with a recess on the side toward said member and a recess on the side toward the companion member, a plate secured to the companion member and situated within the last-named recess, and a bolt extending through the plates having its head located entirely within the first-named recess and being provided with means for preventing its rotation engaging the support.

7. The combination with a pair of members comprising a whiffletree and its support, of a circular plate secured to one of the members provided with a recess on the side toward said member and an annular recess on the side toward the companion member, an annular plate secured to the companion member and situated within the last-named recess, and a bolt extending through the plates having its head located entirely within the plate-recess and being provided with means for preventing its rotation engaging the support.

8. The combination with a whiffletree and its support, of a plate secured to said support, a coacting plate secured to the whiffletree provided with a skirt or flange extending downward about the first-named plate and contacting at all times with the support, and a bolt passing through the plates and support.

9. The combination with a whiffletree and its support, of a plate secured to said support, a coacting plate secured to the whiffletree provided with a skirt or flange extending downward about the first-named plate and contacting with the support, and a bolt provided with a squared portion passing through the plates and engaging the support whereby the rotation of said bolt is prevented.

10. A mounting for whiffletrees comprising a pair of coacting plates, and a bolt carrying a nut passing through the plates and adapted to turn freely therein and provided with lateral projections extending outside the plates on the side toward the nut.

11. A mounting for whiffletrees comprising a pair of coacting plates, and a bolt carrying a nut passing through the plates and adapted to turn freely therein and provided with a squared portion extending outside the plates on the side toward the nut.

12. A mounting for whiffletrees comprising a plate provided with a countersunk recess and an oppositely-placed annular recess and being substantially equal in thickness to the desired distance between the whiffletree and its support, an annular plate adapted to occupy the recess in the first plate, and a bolt provided with a squared portion passing through the plates and having its head situated in the countersunk recess.

13. A mounting for whiffletrees comprising a pair of coacting plates one of which is provided with a projection at its outer side adapted to be forced into the member to which it may be secured, and a bolt passing through the plates and carrying a nut on the side at which the projection is situated.

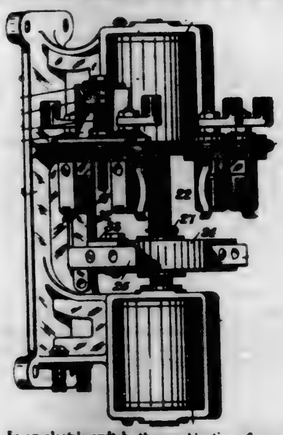
14. A mounting for whiffletrees comprising a pair of coacting plates one of which is provided with an annular reduced or sharpened projection at its outer side adapted to be forced into the member to which it may be secured, and a bolt passing through the plates and carrying a nut on the side at which the projection is situated.

708,005. ARTIFICIAL LEG. HILBE C. BALDWIN, Elmira, N. Y., assignor of one-half to Thomas R. Stevenson, Elmira, N. Y. Filed Apr. 4, 1902. Serial No. 101,230. (No model.)

Claim.—1. A joint for artificial legs comprising a tenon on one member integral therewith pivoted in a mortise in a second member, said second member having cheeks at each side of the mortise cut on a circle with the pivot as a center, the first member being recessed at each side of the tenon to fit said cheeks, and spring or cushion blocks set in sockets at the front and rear of the joint.

2. A joint for artificial legs comprising a tenon on one member integral therewith pivoted in a mortise in a second member, with side straps passing from the pivot-pin to fastening-points on the first member, and spring-blocks to hold the members in normal relation and allow for their required relative movements in walking.

708,006. ELECTRIC SWITCH. HENRY P. BALL, New York, N. Y., assignor to General Incandescent Arc Light Company, a Corporation of New York. Filed Mar. 21, 1901. Serial No. 52,157. (No model.)

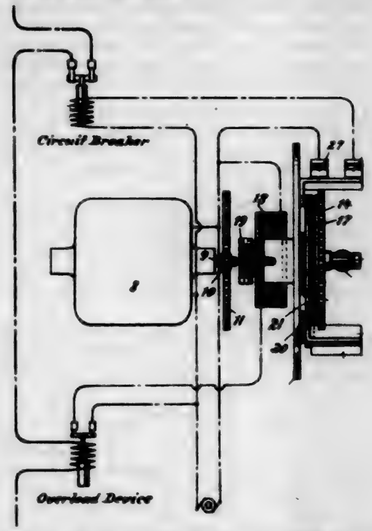


Claim.—1. In an electric switch, the combination of a pair of solenoids in line, a series of spring-terminal contacts, a reciprocating bridge device, an armature actuated by one of said solenoids and fixed to said bridge device, and an armature actuated by the other of said solenoids and elastically connected to said bridge device.

2. In an electric switch, the combination of a pair of solenoids in line, a series of spring-terminal contacts, a reciprocating bridge device, an armature actuated by one of said solenoids and fixed to said bridge device, and means actuated by the other of said solenoids for imparting a hammer-blow to said bridge device.

3. In an electric switch, the combination of a pair of solenoids arranged in line, a series of spring-terminal contacts, a reciprocating bridge device, an armature actuated by one of said solenoids and fixed to said bridge device, an armature actuated by the other of said solenoids, and a spring between said armature and said bridge device.

708,007. TIME-LIMIT DEVICE FOR CIRCUIT-BREAKERS. HENRY P. BALL, New York, N. Y., assignor to General Incandescent Arc Light Company, a Corporation of New York. Filed Jan. 30, 1902. Serial No. 91,742. (No model.)



Claim.—1. In a device such as described, the combination of a rotating member, a circuit-closing member, electromagnetic means for engaging said members, and means for returning the circuit-closing member to its original position upon the cessation of an overload.

2. In a device such as described, the combination of a rotating member, a circuit-closing member, electromagnetic means for engaging said members upon the existence of an overload, means for returning the circuit-closing member to its original position upon the cessation of an overload, and means for limiting the degree of movement of the circuit-closing member.

3. In a device such as described, the combination of a rotating member, a rotatable member, electromagnetic means for engaging the rotating member and the rotatable member, and means for restoring the rotatable member to its original position when the electric energy which energizes the electromagnetic means falls below a predetermined point.

4. In a device such as described, a rotating member, a rotatable member, electromagnetic means for engaging the rotating and rotatable members, means for limiting the degree of rotation of the rotatable member, means for restoring the rotatable member to its original position, and a circuit-closing device carried by the rotatable member.

5. In a device such as described, the combination of a circuit-closing member, means for imparting a definite speed of movement forward to the circuit-closing member upon the creation of an overload, means for limiting the degree of movement of the circuit-closing member, and means for imparting a definite speed of movement backward to the circuit-closing member upon the cessation of an overload.

6. In a device such as described, the combination of a rotating member, a circuit-closing member, electromagnetic means for engaging said members upon the existence of an overload, means for returning the circuit-closing member to its original position upon the cessation of an overload, and means for adjusting the range of movement of the circuit-closing member.

7. In a device such as described, the combination of a circuit-closing device cut in relation by the creation of an overload on the circuit in which it is connected, means for limiting the motion of said circuit-closing device, and means for imparting a reverse motion to the circuit-closing device immediately upon the cessation of an overload.

8. A device such as described, comprising a motor, a disk driven by said motor, a second disk, means for moving said second-named disk into frictional relation with said first-named disk upon an overload, a bridge device carried with said second-named disk, a pair of contacts with which said bridge device coacts, means for separating the disks when the over-

head ceases, and means for determining the time limit within which the device will act.

9. A device such as described, comprising a motor, a disk driven by said motor, a second disk, means for moving said second disk into frictional relation with said first-named disk upon an overload, a bridge device carried with said second-named disk, a pair of contacts with which said bridge device coacts, means for separating the disks and restoring the second-named disk and bridge device to their original position, and means for determining the time limit within which the device will act.

10. In a device such as described, the combination of a driven disk, a second disk, means for moving said second disk into frictional relation with said first-named disk upon an overload, means for determining the period of rotation of the second-named disk, and a circuit-making device actuated by said second-named disk.

11. In a device such as described, the combination of a driven disk, a second disk, means for moving said disk into frictional relation with said first-named disk upon an overload, means for determining the degree of rotation of the second-named disk, and a circuit-making device actuated by the second-named disk.

12. In a device such as described, the combination of a driven disk, a second disk, means for moving said second disk into frictional relation with said first-named disk, means for restoring said second-named disk to its original position after the frictional relation with the first-named disk has ceased, means for limiting the degree of movement of the second-named disk, and a circuit-making device actuated by the second-named disk.

13. In a device such as described, the combination of a driven disk, a second disk, means for moving said second-named disk into frictional relation with said first-named disk, a contact-making device actuated by said second-named disk, and a disk provided with means for limiting the range of movement of the second-named disk.

14. In a device such as described, the combination of a driven disk, a second disk, means for moving said second disk into frictional relation with said first-named disk, a bridge device carried by said second-named disk, a pair of contacts with which said bridge device coacts, a disk having spaced openings, and a pin adapted to be placed in said openings which will coact with the bridge device and limit the movement of said device.

15. In a device such as described, the combination of a driven disk a second reciprocating disk, means for reciprocating said second disk toward and from the first-named disk, a bridge device carried by said second-named disk, a pair of contacts with which said bridge device coacts, and means for adjusting the range of movement of the bridge device.

16. In a device such as described, the combination of a driven disk, a second disk carrying a bridge device, an electromagnet, an armature for said magnet, a pin between said armature and said second-named disk, means for separating the first and second named disks, and means for rotating the second-named disk to its original position.

17. In a device such as described, the combination of a driven disk, a disk to be driven, a bridge device carried by said second-named disk, a disk over the periphery of which said bridge device travels, and means carried by said third disk for limiting the movement of the bridge device over its periphery.

18. A device such as described, comprising a driven disk, a second disk, electrically-actuated means for moving said second disk into operative relation with said first-named disk, a bridge device carried by said second-named disk, a pair of contacts, with which said bridge device coacts, means for determining the range of movement of the bridge device, and means for restoring the bridge device to its original position when the electrically-actuated means for throwing the disks into contact is not active.

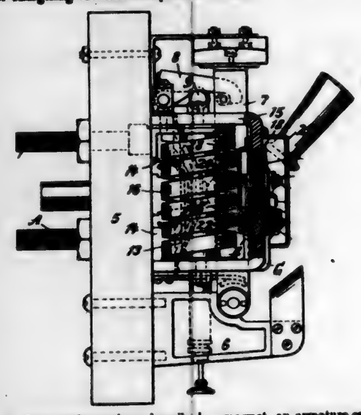
708,008. REVERSE-CURRENT DEVICE FOR CIRCUIT-BREAKERS. HENRY P. BALL, New York, N. Y., assignor to General Incandescent Arc Light Company, a Corporation of New York. Filed Jan. 28, 1902. Serial No. 91,744. (No model.)

Claim.—1. In a device such as described, a magnet, an armature comprising a fixed core and a pivoted oscillating coil, an auxiliary magnet, and means carried by the coil for closing a circuit through the auxiliary magnet when the direction of current through the first-named magnet is reversed.

2. In a device such as described, a magnet, an armature comprising a fixed core and an oscillating coil pivoted at its center, an auxiliary magnet, and means carried by the coil for closing an electric circuit through the auxiliary magnet.

3. In a device such as described, a magnet, an armature comprising a fixed core and a pivoted oscillating coil, an auxiliary magnet, means carried by the coil for connecting said coil in circuit with a source of energy, and means carried by the coil for establishing an electric circuit through the auxiliary magnet.

4. In a device such as described, a magnet, provided with a coil, an armature having a fixed core and oscillating coil, the coil of the magnet and armature adapted to be connected in parallel to the source of energy, an electroresponsive device, and means carried by the coil of the armature for energizing the electroresponsive device.



5. In a device such as described, a magnet, an armature carrying a coil in circuit with a source of energy, an electroresponsive device, and means carried by the armature for closing the current through the electroresponsive device.

6. In a device such as described, the combination of a magnet, a pivoted armature carrying a coil, depending fingers from the terminals of said coil, mercury-cups attached to the terminals of the source of energy, an electroresponsive device connected through one terminal to the source of energy and through the other terminal to a mercury-cup under the armature, and a depending finger carried by said armature which when immersed in the last-mentioned mercury-cup will close a circuit through said electroresponsive device.

7. In combination with a circuit-breaker, a device adapted to trip the circuit-breaker, said device consisting of a fixed member and an oscillating member, both members permanently in circuit with a source of energy, an auxiliary magnet, and a device carried by the oscillating member for closing a circuit through the auxiliary magnet upon a reversal of current from the source of energy.

8. In combination with a circuit-breaker, a reverse-current device comprising a magnet having a coil, an armature having a fixed core and a movable coil, said coils connected in parallel with each other and in series with the magnet of the circuit-breaker, and means energized by the movement of the armature-coil to open said circuit-breaker when the normal angular inclination of the armature is altered.

9. In a device such as described, the combination of a supporting-base, a frame projecting therefrom, a magnet, pivotal bearings on said frame, an armature-coil adapted to oscillate in said bearings, a fixed core for the armature, a series of troughs supported by said frame and carrying a conducting liquid, and fingers carried by said coil adapted to coact with the liquid in said troughs.

708,009. RAIL-JOINT. MAX BARSCHALL, New York, N. Y., assignor to The FIRM Ausbeserungen fuer Eisenbahn Oberbau, Abth. Stossfangschiene, Stegm. Eppenstein, Berlin, Germany. Filed Jan. 6, 1902. Serial No. 88,513. (No model.)

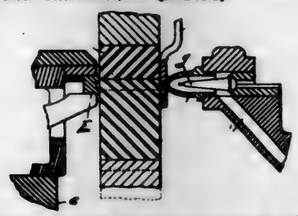
Claim.—1. A rail-joint comprising in combination a main rail, an auxiliary rail, the head of which abuts against the main rail, a double-headed filling-piece arranged between the webs of the said rails, the web of the auxiliary rail being of relatively small thickness at the points where it is engaged by the said filling-piece, and of increased thickness between said points, and means for connecting the auxiliary rail with the main rail.

2. A rail-joint comprising in combination a main rail, an auxiliary rail, the head of which abuts against that of the main rail, said auxiliary rail having a web with relatively thin portions adjacent to its head and base and with a central portion of greater thickness, a filling-piece located between the webs of the main rail and the auxiliary rail and provided with heads which engage the web of the auxiliary rail at the thin portions thereof, and bolts passing through the webs of the rails and loosely through the web of the filling-piece.

3. A rail-joint comprising a main rail, an auxiliary rail abutting against it and provided with an outwardly-thickened web portion provided with a longitudinal groove, a filling-piece located between the webs of the main rail and the auxiliary rail, and bolts connecting the said rails and having angular heads seated in the groove of the auxiliary rail.

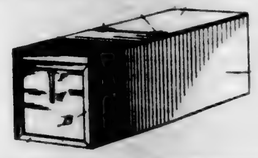
4. A rail-joint comprising a symmetrical main rail, an auxiliary rail having a head of the same width as that of the main rail, and also having a web located symmetrically to the head adjacent to the said head and to the base, and of relatively small thickness at these points, the intermediate or central portion of the web being of increased thickness, a double-headed filling-piece, the heads of which engage the web of the main rail and also engage the web of the auxiliary rail at the thin portions thereof, and connecting-bolts extending through the webs of the rails and loosely through the web of the filling-piece.

708,010. TYPE-CASTING. HENRY BARTH, Cincinnati, Ohio. Filed Nov. 8, 1900. Serial No. 36,022. (No model.)



Claim.—In a type-casting machine a mold consisting of side members, a sliding cover on the side members, a matrix, a carriage to advance it to cover one end of the mold, a nipple covering the other end of the mold for the admission of molten metal, a plunger between the side members, the matrix and the nipple, means for actuating the sliding cover, and the matrix and means for keeping the body-piece or plunger against the cover until all the parts of the mold are closed and for then drawing it away from said cover to form a vacuum-chamber, substantially as shown and described.

708,011. EGG-CASE. JOHN A. BASTLE and HENRY H. WEBER, Chicago, Ill. Filed Mar. 13, 1902. Serial No. 98,130. (No model.)

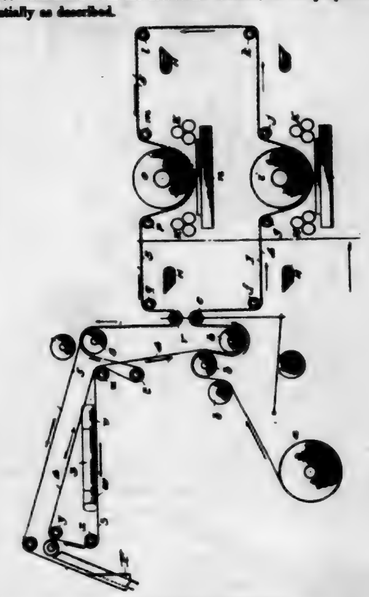


Claim.—An egg-case consisting of two sides, two ends, reinforced by means of four cleats each, the top one having a groove on inner side to permit a steel-wire eye to pass through, a bottom, a partition and a movable cover, the cover being divided in the center and permanently attached together at such division and to the partition by means of a double strap-hinge, the cover having on each end an eye of steel wire, and the case having on each end a steel spring-catch just beneath the cleat to meet and catch the steel-wire eye.

708,012. MULTICOLOR-PRINTING. HENRY F. BECHHAM, Battle creek, Mich., assignor to the Duplex Printing Press Company, Battle creek, Mich. Filed July 15, 1901. Serial No. 68,376. (No model.)

Claim.—1. The herein-described method of printing and perfecting a multicolor-sheet on an ordinary press, consisting in arranging page-forms for multicolored pages side by side transversely of the press in each printing mechanism, of a press having a plurality of printing mechanisms, providing the proper color ink-supply for each form on each printing mechanism, and leading the web successively through both printing mechanisms over one set of page-forms therein to perfect the web and immediately returning the web through both sets of printing mechanisms over the other set of page-forms therein, the impressions taken from the different forms in each printing mechanism being superimposed, all substantially as and for the purpose described.

2. The herein-described manner of printing a multicolored perfected sheet in a traveling-cylinder perfecting-press, consisting in arranging the different-color page-forms for the same page or pages on the same bed side by side and transversely of the press, providing suitable colored ink-supplies for the respective color-forms, leading the web through the press successively over one set of page-forms on each bed to perfect the web, and immediately returning the web through the feeding and printing mechanisms of the press parallel with its first lead and over the other set of page-forms on each bed, the second series of impressions taken from the second forms on the beds being superimposed on the first series of impressions taken from the first forms thereon, for the purpose and substantially as described.



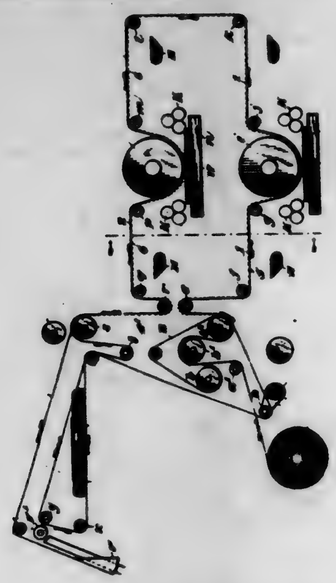
708,018. MACHINE FOR MULTICOLOR-PRINTING. HENRY F. BECHHAM, Battlecreek, Mich., assignor to the Duplex Printing Press Company, Battlecreek, Mich. Filed Jan. 15, 1902. Serial No. 89,893. (No model.)

Claim.—1. In a multicolor web-perfecting printing-press, the combination of two printing-couples, a plurality of multicolor page-forms arranged in each couple side by side and transversely of the press, a suitable color ink-supply for each form in each printing-couple, means for leading a web successively through both printing-couples over one set of forms therein and taking perfected impressions therefrom; and means for again passing the web successively through both printing-couples over the other set of forms therein and taking perfected impressions therefrom, the impressions from the different page-forms in each printing-couple being superimposed, substantially as described.

2. In a multicolor web-perfecting printing-press, the combination of two printing-couples, a single feed mechanism, and a single delivery mechanism, a plurality of multicolor page-forms arranged in each printing-couple side by side and transversely of the press, a suitable color ink-supply for each form in each printing-couple; means for leading a web from the feed to the delivery successively through both printing-couples over one set of forms therein and taking perfected impressions therefrom; means for diverting the web to one side, and means for again passing the web from the feed to the delivery through both printing-couples over the other set of forms therein and taking perfected impressions therefrom, and means for diverting the web out of the press after it passes the delivery-rolls the second time, substantially as described.

3. In a multicolor perfecting-press, the combination of a pair of printing-couples, a single set of feed-rolls, a single set of delivery-rolls, and guides for directing the web from the feed-rolls through the printing-couples to the delivery-rolls; with means for diverting the web as it first issues from the delivery-rolls to one side, means for directing the deflected portion of the web around the feed-rolls, back into the press, and leading it again between the printing-couples parallel with its first lead therethrough back to the delivery-rolls, and means for directing the web into

ing the second time from the delivery-rolls out of the machine, all substantially as and for the purpose set forth.



708,014. OYSTER-OPENING TOOL. SILLIMAN BLAGDEN, Boston, Mass. Filed Apr. 29, 1902. Serial No. 105,153. (No model.)

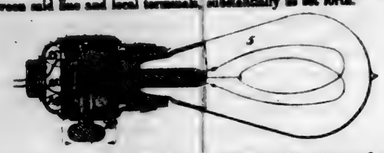
Claim.—An oyster-opening tool consisting of a pair of hinged lever-arms, each having a short and long leg, an anvil on one of said short legs, and a knife-blade on the other short leg, said blade being mounted thereon at an angle inclined thereto and depending inwardly toward the hinge of the tool as and for the purpose herein set forth.

708,015. SHELF-BENDING MACHINE. GEORGE G. BLAKEY and ROBERT O. BLAKEY, Pittsburg, Pa. Filed Nov. 1, 1901. Serial No. 80,745. (No model.)

Claim.—In a strip or strap bending machine, a die, a ram to push the end of a strip against and around the face of said die to form an eyelet and a lever actuated by the ram on its return movement, whereby the eyelet is discharged from said die.

708,016. REGULATING-SOCKET. LOUIS F. ROSSA, Jr., Philadelphia, Pa. Filed Sept. 20, 1901. Serial No. 75,726. (No model.)

Claim.—1. In a regulating-socket, the combination with a frame of resistance material, comprising annular flanges connected by a hub of reduced diameter and forming an annular space; of line-terminals and local terminals connected to said frame; a resistance medium secured to the inner face of one of said flanges at one side of said annular space; and a movable contact member, mounted on said hub and arranged to contact with said resistance medium to vary the extent of said resistance medium interposed between said line and local terminals, substantially as set forth.



2. In a regulating-socket, the combination with a frame of resistance material comprising annular flanges connected by a hub of reduced diameter and forming an annular space; of line-terminals and local terminals connected to said frame; a resistance medium secured to the inner face of one of said flanges; and a movable contact member, mounted between said flanges and arranged to contact with said resistance medium to vary the extent of said resistance medium interposed between said line and local terminals, substantially as set forth.

3. In a regulating-socket, the combination with a frame of resistance material comprising two members, having an annular space between them; the first of said members being provided with a reduced portion and the second member with a socket to receive the reduced portion of the first member; of a resistance medium secured to the inner face of one of said members; and a movable contact member mounted on said reduced portion arranged to contact with said resistance medium to vary the extent of said resistance interposed between said line and local terminals, substantially as set forth.

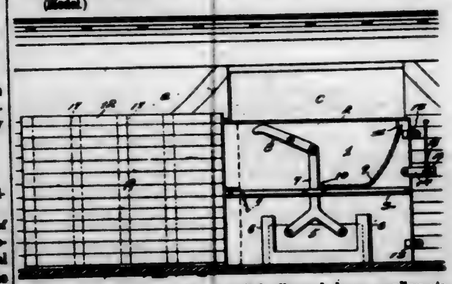
4. In a regulating-socket, the combination with an outer shell comprising two parts; of a ceramic frame comprising two parts fixed to the respective parts of the shell so as to maintain an annular space between them; line-terminals fixed to one member of said frame; local terminals fixed to the other member of said frame; a conductor connecting one of said line-terminals with one of said local terminals, and arranged to hold the two members of the frame together; a resistance medium fixed to one member of said frame and permanently connected at one extremity to the other of said local terminals; a rotary contact device arranged to connect said resistance medium and the other of said line-terminals; and means to shift said contact device to vary the resistance interposed between said line and local terminals, substantially as set forth.

5. In a regulating-socket, the combination with an outer shell; of line-terminals and local terminals stationary in said shell; an annular body of resistance medium within said shell; a contact-roller mounted within said shell to traverse said resistance medium; and means to shift said roller and thereby vary the resistance interposed in the circuit between said line and local terminals, substantially as set forth.

6. In a regulating-socket, the combination with an outer shell; of line-terminals and local terminals stationary in said shell; an annular body of resistance medium within said shell; a contact-lever mounted to rotate within said shell; a yoke pivoted to said contact-lever; a contact-roller mounted for rotation in said yoke; and a spring arranged to press said roller in contact with said resistance medium, substantially as set forth.

7. In a regulating-socket, the combination with an outer shell; of line-terminals and local terminals stationary in said shell; an annular body of resistance medium within said shell; a contact-lever mounted within said shell to traverse said resistance medium; an operating-lever coupled to said contact-lever and arranged for definitely-limited motion with respect thereto; and a spring connecting said contact-lever with said operating-lever, substantially as set forth.

708,017. GRAIN-DOOR FOR CARS. THOMAS H. DOS DURANT, Moundridge, Kans. Filed Apr. 26, 1902. Serial No. 104,668. (No model.)



Claim.—1. A car having oppositely-disposed doors, coupling elements connected thereto and adapted to be disposed across the car and to be connected together, for the purpose set forth, said doors having supports on their inner sides for said coupling elements, when the latter are disconnected from each other, substantially as described.

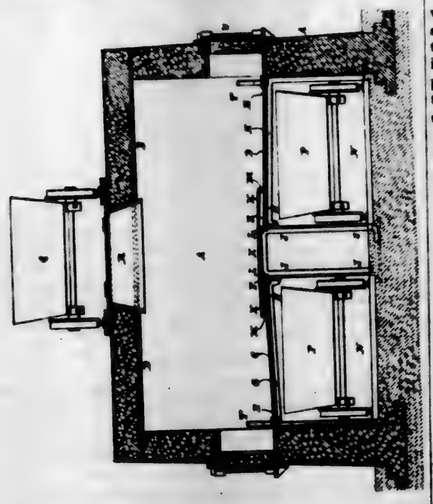
2. A car having oppositely-disposed sliding doors, casings to receive the doors when the same are opened, flexible coupling elements connected to the doors and adapted to be connected together when the doors are closed, for the purpose set forth, said doors being provided on their inner sides with longitudinally-disposed bars forming supports for said coupling elements when the latter are disconnected from each other and the doors are opened, substantially as described.

3. A grain-door for cars, made of sheet or plate metal having its upper side bent laterally to strengthen the same, having a longitudinally-disposed bar on its inner side at a point intermediate the upper and lower sides of the door, a coupling-chain secured at one end to the door above the bar, and a support carried by the door, to detachably engage the free end of the coupling-chain, substantially as described.

4. A car having oppositely-disposed doors, flexible elements connected thereto and means to secure said flexible elements together when the doors are closed to brace the doors against the outward pressure of the grain, substantially as described.

5. A car having oppositely-disposed doors, and coupling elements connected thereto and adapted to be disposed across the car and to be connected together, to brace the doors against the outward pressure of the material with which the car is loaded, substantially as described.

708,018. UTILIZING WASTE HEAT IN CONNECTION WITH SMELTING-FURNACES. RICHARD BROWN, Southampton, England. Filed Apr. 12, 1902. Serial No. 102,503. (No model.)

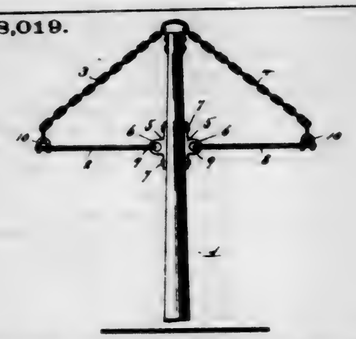


Claim.—Apparatus for utilizing waste heat in connection with smelting-furnaces, comprising a covered chamber to receive the materials in the furnace, having a floor and supported so as to form flues to receive bogies containing hot products from the furnace, the floor having openings adapted to allow air heated by contact with the hot products to ascend through the materials thereon, substantially as described.

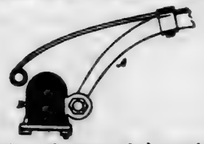
708,019. NECK-YOKE. ANDREW BURR, Columbia City, Ind. Filed Nov. 2, 1901. Serial No. 80,982. (No model.)

Claim.—The combination with a pole having a ring rigidly secured to the front end thereof, of brackets attached to diametrically opposite portions of the pole in rear of the front extremity and provided with central perforations, rods 6 having their inner ends loosely connected to the perforations of the brackets and their outer ends screw-threaded, U-shaped links 10 each having the terminals formed into eyes, one of which is screw-threaded and the other large enough to slip over the threads on the outer end of the rod whereby the said links may be positively applied to the rods, and chains 3 connected to the ring at the front end of the pole and the links 10, the latter being slipped through the rear links of the said chains.

708,019.

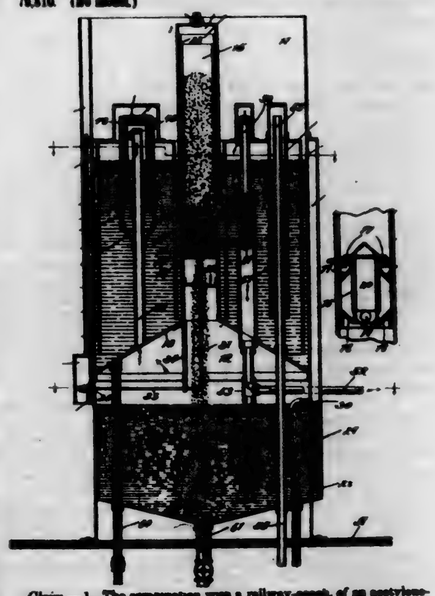


708,020. VEHICLE-SHAFT SUPPORT. IRA D. CADY, Minneapolis, Minn. Filed Dec. 16, 1901. Serial No. 86,012. (No model.)



Claim.—A device of the type set forth comprising in combination with the axle and the shafts, a clamp adjustably mounted upon the shafts, and a supporter formed of an integral piece of wire bent into a U shape, the free ends of the wire being bent upwardly and immovably secured in the clamp, and a single coil formed on the looped portion of the supporter, the rear portion of the supporter being bowed and the coil frictionally engaging the under side of the axle for securing the shaft, substantially as described.

708,021. ACETYLENE-GAS GENERATOR. CHARLES W. CALDWELL, Waterloo, Iowa, assignor to the Railroad Gas Lighting Company, Chicago, Ill., a Corporation of Illinois. Filed Oct. 24, 1901. Serial No. 79,510. (No model.)



Claim.—1. The combination with a railway-coach, of an acetylene-gas-generating apparatus secured within the same and projecting through the roof of the coach, substantially as specified.

2. The combination with a railway-coach, of an acetylene-gas-generating apparatus secured within the same and projecting through the roof

of the coach, said apparatus comprising a fixed portion open at its upper end, and a movable bell within said fixed portion, whereby upon the overturning of the coach said bell will be displaced and release the gas confined thereby, substantially as specified.

3. The combination with a railway-coach, of an acetylene-gas-generating apparatus secured within the same and projecting through the roof of the coach, and pipes leading from the interior of the said apparatus through the floor of the coach, to permit the liquid and solid contents of the apparatus to be drawn off and discharged beneath the coach, substantially as specified.

4. In an acetylene-gas-generating apparatus, the combination with a gas-generating chamber, and a gas-holding bell adapted to receive gas from said chamber and hold it, of a carbid-holder arranged concentrically with said gas-holding bell, a vertical valve-casing, open at its lower end, carried by that portion of the holder within the gas-holding bell and provided with an opening in the side wall thereof through which carbid is adapted to pass, a vertically-movable hollow valve located in said casing, and adapted to normally close the said opening in the wall of the casing, a rod adapted to enter said hollow valve and abut against the end wall thereof, and means for forcing said rod upward to raise said valve, said means being actuated through the downward movement of said bell, substantially as specified.

5. In an acetylene-gas-generating apparatus, the combination with a gas-generating chamber, and a gas-holding bell adapted to receive gas from said chamber and hold it, of a carbid-holder arranged concentrically with said gas-holding bell, a vertical valve-casing, open at its lower end, carried by said holder and provided with an opening in the side wall thereof through which carbid is adapted to pass, an inclined plate adapted to direct carbid toward said side-wall opening, a vertically-moving valve located in said valve-casing and adapted to normally close said side-wall opening in the casing, and means for actuating said valve through the movement of the bell, substantially as specified.

6. In an acetylene-gas-generating apparatus, the combination of a gas-generating chamber, and a gas-holding bell adapted to receive gas from said chamber and hold it, of a carbid-holder communicating with said gas-generating chamber and provided with a valve for controlling the discharge of carbid, a movable valve-rod, a second rod provided with a crank at each end and connected with said valve-rod through one of said cranks, a lever pivoted to the other of said cranks, means for preventing said lever from turning in one direction on its pivot, and another rod adapted to be actuated by the bell and provided with means for engaging said pivoted lever, whereby through the first two mentioned rods the valve will be opened to permit the discharge of carbid, substantially as specified.

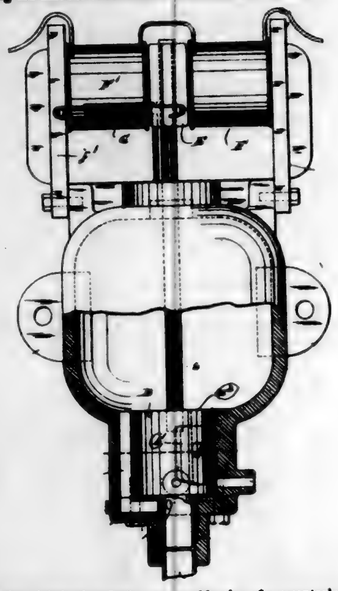
7. In an acetylene-gas-generating apparatus, the combination with a gas-generating chamber, and a gas-holding bell adapted to receive gas from said chamber and hold it, of a carbid-holder communicating with said gas-generating chamber and provided with a valve for controlling the discharge of carbid, a movable valve-rod, a second rod provided with a crank at each end and connected with said valve-rod by means of one of said cranks, a lever pivoted to the other of said cranks, means for preventing said lever from turning in one direction on its pivot, and another rod adapted to be actuated by the bell and provided on its lower end with a fork adapted to contact the said pivoted lever, substantially as specified.

8. In an acetylene-gas-generating apparatus, the combination with a gas-generating chamber, and a gas-holding bell adapted to receive gas from said chamber and hold it, of a carbid-holder communicating with said gas-generating chamber and provided with a valve for controlling the discharge of carbid, a movable valve-rod, a second rod provided with a crank at each end and connected with said valve-rod by means of one of said cranks, a lever pivoted to the other of said cranks, means for preventing said lever from turning in one direction on its pivot, and another rod adapted to be actuated by the bell and provided at its lower end with means for loosely connecting it to said pivoted lever, substantially as specified.

9. In an acetylene-gas-generating apparatus, the combination with a gas-generating chamber, and a gas-holding bell adapted to receive gas from said chamber and hold it, of a carbid-holder communicating with said gas-generating chamber and provided with a valve for controlling the discharge of carbid, a movable valve-rod, a second rod connected at one end with said valve-rod, a lever pivoted to the other end of said second rod, means for preventing said lever from turning in one direction on its pivot, and another rod adapted to be actuated by the bell and provided with means for engaging said pivoted lever, whereby, through the first two mentioned rods, the valve in the carbid-holder can be opened to permit the discharge of carbid, substantially as specified.

708,022. LUBRICATOR. FRANK GARKLOSS, Chicago, Ill., assignor to Morgan-Gardner Electric Company, Chicago, Ill., a Corporation. Filed Aug. 2, 1901. Serial No. 70,710. (No model.)

Claim.—1. In a lubricating device, the combination of a receptacle, a casing at the bottom of said receptacle, inlet and outlet ports in said casing, a valve in said casing with chambers communicating alternately with said inlet and outlet ports, a tubular extension on said valve, a by-pass leading from the receptacle to said extension, a lateral orifice in said extension adapted to register with said by-pass, a stem for said valve, an armature on said stem, a spring holding said valve in a normal position, an electromagnet for turning said stem, and a set-screw in said armature for limiting the amount of revolution, substantially as described.



2. In a lubricating device, the combination of a receptacle, a casing at the bottom of said receptacle, inlet and outlet ports in said casing, a valve in said casing with chambers communicating alternately with said inlet and outlet ports, a tubular extension on said valve, a by-pass leading from the receptacle to said extension, a lateral orifice in said extension adapted to register with said by-pass, a stem for said piston and means for turning said stem.

708,028. ENGINE ATTACHMENT. VIRGINIUS X. CARACHEO, Granite, Va. Filed June 19, 1901. Serial No. 65,168. (No model.)

Claim.—1. The combination with a locomotive or engine cylinder having a piston-rod, of an extension-bearing of approximate wedge shape arranged in advance of said cylinder, and means for adjusting said bearing.

2. The combination with a locomotive or engine cylinder having a piston-rod, of an extension-bearing secured to the front end of said cylinder, said bearing being of wedge shape, and means for adjusting said bearing.

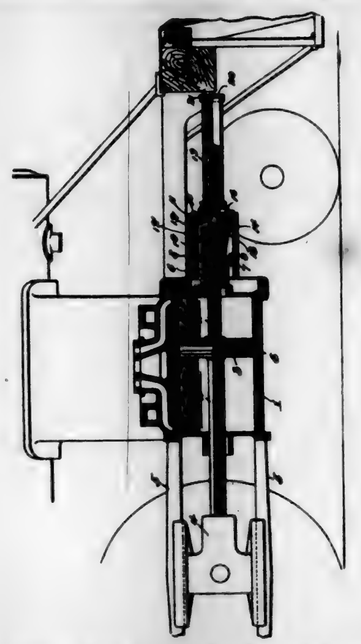
3. The combination with a locomotive or engine cylinder having a piston-rod, of an extension-bearing secured to the front end of said cylinder and provided with upper and lower bearing-blocks, and means for adjusting one of said blocks.

4. The combination with a locomotive or engine cylinder having a piston-rod, of an extension-bearing secured to the front end of said cylinder and provided with upper and lower bearing-blocks, said lower block being of wedge shape, and means for adjusting said wedge-shape block.

5. The combination with a locomotive or engine cylinder having a piston-rod, of an extension-bearing secured to the front end of said cylinder, a coupling extending from said extension-bearing, and a protecting-sleeve carried by said coupling.

6. The combination with a locomotive or engine cylinder having a piston-rod, of an extension-bearing having flanges, one of which is secured to the front end of said cylinder, a coupling extending from the other flange of said bearing, a protecting-sleeve carried by said coupling, and a screw secured to the free end of said sleeve.

7. The combination with a locomotive or engine cylinder having a piston-rod, of an extension-bearing having flanges, one of which is secured to the front end of said cylinder, bearing-blocks carried by said bearing and a protecting-hood surrounding the peripheries of said flanges.



8. The combination with a locomotive or engine cylinder, of an extension-bearing secured to the front end thereof and provided with upper and lower bearing-blocks, means for adjusting the bearing, a coupling covering such means, and a protecting-sleeve connected to and extending from such coupling.

9. The combination with a locomotive or engine cylinder, of an extension-bearing secured to the front end thereof and provided with upper and lower bearing-blocks, the latter being wedge-shaped, means for adjusting the lower block and a securing-bolt tapped into the lower side thereof and mounted in a slot in the extension-bearing.

10. The combination with a locomotive or engine cylinder, and its described piston, of an extension-bearing of tubular shape the bottom of which is inclined or flared toward the outer end thereof, upper and lower bearing-blocks located in the extension and fitting the same, an adjusting means for the lower bearing, and a binding-bolt for securing the same after such adjustment.

11. The combination with a locomotive or engine cylinder, and its piston-rod, as described, of a tubular extension-bearing, the bottom of which is inclined, upper and lower bearing-blocks located in the extension, the lower block being wedge-shaped to accord with the extension, a follower-plate located beyond the lower block, bolts extending through the plate and swiveled in the extension, and a covering for the outer ends of the bolts.

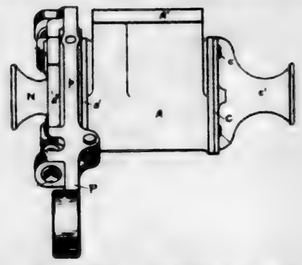
12. The combination with a locomotive or engine cylinder, and its piston-rod as described, of a tubular bearing extension, the bottom of which is inclined, upper and lower bearing-blocks located in the extension, the latter block being wedge-shaped to accord with the bottom of the extension, a follower-plate located beyond the lower block, bolts extending through the plate and through the extension a coupling bolted to the extension and covering the outer ends of the bolts, a protecting-sleeve connected to the coupling, and a screw at the outer end of said sleeve.

13. The combination with a locomotive or engine cylinder, and its described piston-rod, of a tubular bearing extension, the bottom of which is inclined, upper and lower bearing-blocks located in the extension, the lower block being wedge-shaped to accord with the bottom of said bearing extension, a follower-plate located beyond the lower block, bolts extending through the plate and extension and provided with nuts at their rear ends, a swab-cap, and a coupling inclosing the same and covering the outer ends of the bolts.

14. The combination with a locomotive or engine cylinder, and its described piston, of a tubular oppositely-flanged bearing extension bolted to the cylinder and having its bottom inclined and provided with a slot, upper and lower bearing-blocks mounted in the extension, the lower block being wedge-shaped to accord with the bottom of the extension, a protecting-casing fitting over the flanges of the extension a binding-bolt passed through the slot in the bearing extension and entering the bottom bearing-block, a swab-cap covering the end of the extension, and a cover for the swab-cap.

15. The combination with a locomotive or engine cylinder, and its piston-rod, of a tubular extension-bearing located at the front end of the cylinder and provided with laterally-disposed counterweak ears having holes, upper and lower bearing-blocks located in the bearing, the latter block being wedge-shaped to accord with the inclined bottom of the bearing, a follower-plate located against the front end of the latter block, and bolts passed through the follower-plate and through the holes in the counterweak ears and in rear of the latter provided with nuts.

708,024. COUPLING FOR ELECTRIC MOTORS. FRANK H. CLARK, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Feb. 15, 1901. Serial No. 47,414. (No model.)



Claim.—1. In a coupler for electric conductors, the combination with a casing, of a block of insulation, a metallic socket-piece mounted therein, and contact-brushes secured to said socket-piece.

2. In a coupler for electric conductors, the combination with a casing, of a block of insulation, a metallic socket-piece mounted therein, and contact-brushes secured to said socket-piece, having their ends terminating in a plane transverse to the axis of the casing.

3. The combination with a receptacle provided with a cylindrical surface, of a plug fitting into the receptacle, a collar rotatable on the cylindrical surface, and spring-actuated hooks on the collar to engage with the plug.

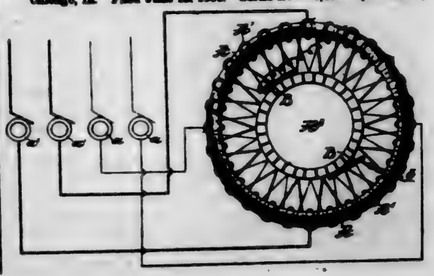
4. The combination with a receptacle provided with a cylindrical surface, of a plug fitting into the receptacle, and provided with chamfered flanges, and a collar rotatable on the cylindrical surface and carrying yielding hooks having chamfered ends to engage with said flanges.

5. In a coupler for electric conductors, the combination with a casing, of a block of insulation, and a metallic socket-piece mounted therein, and having arms to carry contact-brushes.

6. In a coupler for electric conductors, the combination with a casing, of a block of insulation removably secured therein, a socket-piece mounted in said block and having arms, and a brush secured to each arm.

7. In a coupler for electric conductors, the combination with a casing, of a block of insulation removably secured therein, a socket-piece mounted in said block, arms projecting from said socket-piece, and a brush on each arm, said brushes being inclined toward each other and having their ends cut off on a plane transverse to the axis of the casing.

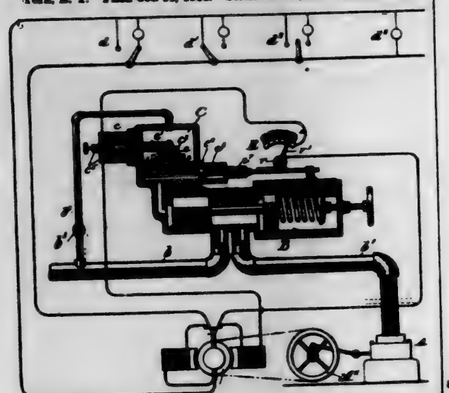
708,025. ROTARY TRANSFORMER. ALEXANDER GRAMME, Chicago, Ill. Filed June 13, 1898. Serial No. 790,186. (No model.)



Claim.—1. A rotary transformer for multiphase systems provided with a plurality of armature-windings corresponding in number to the number of phases in the system, a separate pair of collector-rings connected with each winding, and a separate set of commutator-bars connected with each winding, whereby the phases are maintained independent of each other.

2. A rotary transformer for multiphase systems provided with a plurality of armature-windings corresponding in number to the number of phases of the system, a separate pair of collector-rings connected with each winding, and a separate commutator for each winding.

708,026. ELECTRIC CONTROLLER. WILLIAM H. CLARKE, New York, N. Y. Filed Oct. 11, 1901. Serial No. 78,217. (No model.)



Claim.—1. In an electric regulator, the combination of a motor, a differential piston controlling the motor, a generator operated by said motor, an electric circuit connected therewith, a rheostat in said circuit, and means governed by the differential piston and rheostat for maintaining a constant speed of the motor, substantially as described.

2. In an electric regulator, the combination of a generator, a rheostat and a solenoid included in the field-circuit of said generator, a piston connected with the rheostat, and a valve operated by the solenoid and controlling the admission of fluid-pressure to said piston, substantially as described.

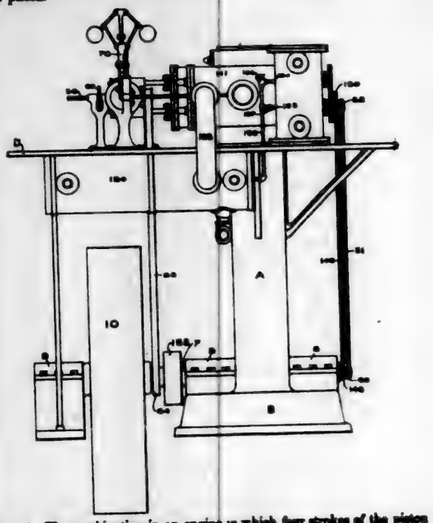
3. In an electric regulator, the combination of a fluid-pressure motor, an electric generator operated by said motor, a reducing-valve governing the admission of fluid-pressure to said motor, an electromagnetic valve connected with the generator, a rheostat in the field-circuit of the generator, a fluid-pressure motor for the rheostat, and a part or passage governed by said electromagnetic valve for admitting pressure to the rheostat-motor and the reducing-valve, substantially as described.

4. In an electric regulator, the combination of a fluid-pressure motor, a generator operated by said motor, a circuit connecting the armature-terminals of said generator, a shunt-shunting switch for said circuit, and means governed by said switch for cutting off the supply of fluid-pressure to the motor, substantially as described.

708,027. AIR-SUPPLY DEVICE. EDWARD J. CHESHAM, St. Paul, Minn. Filed Sept. 3, 1901. Serial No. 74,031. (No model.)

Claim.—1. The combination in an engine in which four strokes of the piston and two revolutions of the crank-shaft are comprised in a working cycle, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber, heating means therefor, and valves interposed between said air-chamber and piston-cylinder said parts being so arranged and connected that air is compressed by the piston from atmospheric pressure and temperature into said air-chamber and the clearance-space of the cylinder, during the latter half of the second stroke of the cycle, retained in said chamber and heated therein during the third and fourth strokes of the cycle, and expanded from said chamber into the cylinder during the first stroke of the following cycle.

2. The combination in an engine in which four strokes of the piston and two revolutions of the crank-shaft are comprised in a working cycle, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber, heating means therefor, and valves interposed between said air-chamber and piston-cylinder said parts being so arranged and connected that air is compressed by the piston from atmospheric pressure and temperature into said air-chamber and the clearance-space of the cylinder during the latter half of the second stroke of the cycle, retained in said chamber and heated therein during the third and fourth strokes of the cycle, and expanded from said chamber into the cylinder during the first stroke of the following cycle, and means for giving initial movement to the piston.



3. The combination in an engine in which four strokes of the piston and two revolutions of the crank-shaft are comprised in a working cycle, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber, heating means therefor, and valves interposed between said air-chamber and piston-cylinder, said parts being so arranged and connected that air is compressed by the piston from atmospheric pressure and temperature, into said chamber and the clearance-space of the cylinder, during the latter half of the second stroke of the cycle, retained in said chamber and heated therein during the third and fourth strokes of the cycle, and expanded from said chamber into the cylinder during the first stroke of the following cycle, and means for giving initial movement to the piston.

4. The combination in an engine in which four strokes of the piston and two revolutions of the crank-shaft are comprised in a working cycle, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber divided into two compartments, heating means therefor, and valves interposed between said air-chamber compartments and piston-cylinder said parts being so arranged and connected that air is compressed by the piston from atmospheric pressure and temperature into said chamber and the clearance-space of the cylinder, during the latter half of the second stroke of the cycle, retained in said chamber and heated therein during the third and fourth strokes of the cycle, and expanded from said chamber into the cylinder during the first stroke of the following cycle, and means for causing initial compression of air in the air-chamber and clearance, substantially as set forth and described.

5. The combination in an engine in which four strokes of the piston and two revolutions of the crank-shaft are comprised in a working cycle, of a cylinder and piston contained therein, a connected crank-shaft, an air-chamber divided into two compartments, heating means therefor, and valves interposed between said compartments and piston-cylinder, said parts being so constructed and arranged that air is substantially compressed by the piston into the clearance-space of the cylinder during the second stroke of the cycle, and expanded into the cylinder during the third stroke of the cycle, thereby doing positive work against the piston during the said stroke, the ratio of expansion during said stroke of the cycle being greater than the ratio of compression of the air in the second stroke thereof, whereby the positive energy of the air expanding in the third stroke is greater than the energy consumed in compressing said air in the second stroke, and means for imparting an initial movement to said piston, thereby compressing air into said clearance during the second stroke of the initial cycle, substantially as set forth and described.

6. The combination in an engine in which four strokes of the piston and two revolutions of the crank-shaft are comprised in a working cycle, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber divided into two compartments, means for heating the contents thereof, of said chamber, an air-reservoir, means for heating the contents thereof, means for compressing air in said reservoir, valves arranged between said

air-chamber compartments and reservoir and said cylinder, whereby the air is admitted from said reservoir to the cylinder during a short part of the beginning of the third stroke and expanded therein against the piston doing positive work during said stroke, the ratio of compression of said air into the reservoir being less than the ratio of expansion of said air in the cylinder during the third stroke of the cycle, whereby the energy derived from the expansion of said air during the said stroke of the cycle is greater than the energy consumed in compressing said air into said reservoir, means for initially compressing the air in said reservoir, and means for imparting initial movement to the operating parts of the engine.

7. The combination in an engine in which four strokes of the piston and two revolutions of the crank-shaft are comprised in a working cycle, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber comprising two independent compartments, one connected with one end of said cylinder, and the other with the other end, means for heating the air in said compartments, valves interposed between each compartment of said air-chamber and said cylinder, an air-reservoir, a compressor arranged in connection therewith, valves interposed between said reservoir and cylinder, the parts being so arranged and connected that air is compressed by the piston from atmospheric pressure and temperature into each compartment of said air-chamber and the clearance-space of said cylinder during the latter part of each alternate return stroke of said cycle and heated therein during the second forward stroke and second return stroke of said cycle and expanded from each of said compartments alternately into the cylinder down to or below atmospheric pressure and temperature, the ratio of expansion in the first forward stroke being greater than the ratio of compression in the first return stroke, whereby the energy derived from the expansion of the air in said first forward stroke is greater than the energy consumed in compressing said air during the latter part of the first return stroke, and the ratio of expansion of the air from the reservoir into the cylinder during the second forward stroke being greater than the ratio of compression of said air into said reservoir by the compressor, whereby the energy developed by said expansion is greater than the energy consumed in said compression, means for regulating the flow of air between said cylinder and air-chamber and external atmosphere, and between the compressor and the reservoir, and a governor for operating said regulating means, substantially as and for the purpose described.

8. The combination in an engine, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber, means for heating the contents of said chamber, an air-reservoir, means for compressing air therein, means for heating the contents thereof, valves arranged between said chamber and reservoir and cylinder, said parts being so arranged and connected that air is compressed by the piston from atmospheric pressure and temperature into said air-chamber and the clearance-space of the cylinder, retained and heated in said chamber, and expanded from said chamber into said cylinder, and is admitted from said reservoir to said cylinder during the stroke of the cycle.

9. The combination in an engine, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber, means for heating the contents of said chamber, an air-reservoir, means for compressing air in said reservoir, means for heating said air, and rotary valves for establishing communication between said air-chamber, said reservoir and said piston-chamber, said parts being so arranged and connected that air is compressed by the piston into said air-chamber, retained and heated in said chamber, expanded from said chamber into said cylinder, and is admitted from said reservoir into said cylinder during the stroke of the cycle

10. The combination in an engine, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber consisting of two compartments, means for heating the contents of said compartments, an air-reservoir, means for compressing air in said reservoir, means for heating said air, a rotary valve for establishing communication between said air-chamber compartments and cylinder, said valve being provided with parts for establishing communication between said cylinder and the outer air, a rotary valve for establishing communication between said reservoir and cylinder, said parts being so arranged and connected that air is compressed by the piston into said chamber, retained and heated therein, and expanded from said chamber into said cylinder, and is admitted from said reservoir into said cylinder during the stroke of the cycle.

11. The combination in an engine, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber consisting of two compartments, means for heating the contents thereof, rotary valves for establishing communication between said compartments and the opposite ends of said cylinder, said valves being provided with parts for establishing communication between said cylinder and the outside air, an air-reservoir, means for compressing air therein, means for heating the same, and rotary valves for establishing communication between said reservoir and cylinder, said parts being so arranged and connected that air is compressed by the piston from atmospheric pressure and temperature into said air-chamber, retained and heated in said chamber, and expanded from said chamber into said cylinder, and is admitted from said reservoir into said cylinder during the stroke of the cycle.

12. The combination in an engine, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber consisting of two compartments, means for heating the contents of said chamber, an air-reservoir, means for compressing air in said reservoir, means for heating said air, rotary valves for establishing communication between the compartments of said air-chamber and said cylinder, and between said reservoir and cylinder, a source of steam-supply, and rotary valves for establishing communication between said steam-supply and cylinder, said parts being so arranged and connected that air is compressed by the piston from atmospheric pressure and temperature into said air-chamber compartments, retained and heated in said compartments, and expanded therefrom into said cylinder, and is admitted from said reservoir to said cylinder during the stroke of the cycle, steam being admitted to said cylinder to impart initial movement to said piston.

13. The combination in a double-acting engine, in which four strokes of the piston, i. e. a first forward stroke, a first return stroke, a second forward stroke, a second return stroke, and two revolutions of the crank-shaft constitute a cycle of operations, of a cylinder, a piston contained therein, a connected crank-shaft, two independent air-chamber compartments connected with opposite ends of the cylinder, means for heating the contents of said compartments, an air-reservoir, means for heating the contents thereof, a compressor actuated by the engine for forcing air into said reservoir, two sets of coöperating air-valves actuated by the engine interposed between the air-chamber compartments, air-reservoir and the cylinder, one set for each end of the cylinder, each of said air-valves being in three divisions, one valve in the first division of each set having a port to open communication between each air-chamber compartment and the corresponding end of the cylinder, during the two first strokes of each cycle, viz. the first forward and the first return, one valve in the second division of each set having two ports one of which opens communication between the cylinder and the external atmosphere, in each last stroke of each cycle, viz. the second return stroke, and the other of which opens communication between the cylinder and the external atmosphere during the first part of each first return stroke, a valve in the third division of each set having a port which opens communication between the air-reservoir, and each end of the cylinder, during the first part of each third stroke of each cycle, viz. the second forward, the parts being so arranged and connected that air is compressed by the piston in the engine-cylinder into each air-chamber compartment during the latter half of each first return stroke, retained in each compartment and heated therein during the second forward and second return strokes, and admitted into the cylinder in each first forward stroke, and expanded into said cylinder during the said stroke down below atmospheric pressure and temperature, the parts being also arranged and connected so that air is compressed by the compressor during the working of the engine into the reservoir, from which it is admitted into each end of the cylinder during the first part of each second forward stroke, and then expanded into said cylinder down below atmospheric pressure and temperature during the remainder of said stroke, a valve controlling communication between the cylinder and the external atmosphere, a valve controlling communication between the compressor and air-reservoir, a governor for said valves actuated by the engine, a steam-boiler, auxiliary valves actuated by the engine for controlling communication between said boiler and the cylinder to regulate the inflow of steam into the cylinder and the effect therefrom for the purpose of starting the engine, a system of four coöperating step-valves, two of which are interposed between the cylinder and the air-valve chest, the other two being interposed between each end of the cylinder and steam-valve chests, and means for actuating said valves simultaneously to throw the steam-valves into communication with the cylinder and out the air-valves out of communication, or to throw the air-valves into communication and out the steam-valves out.

14. The combination in a double-acting engine, in which four strokes of the piston, viz. a first forward stroke, a first return stroke, a second forward stroke, and a second return stroke, and two revolutions of the crank-shaft constitute a cycle of operations, of a cylinder, a piston contained therein, a connected crank-shaft, two air-chamber compartments, means for heating the contents of said compartments, an air-reservoir, means for heating the contents of said reservoir, a compressor actuated by the engine to force air into said reservoir, air-valve chests interposed between each end of the cylinder and the air-chamber compartment and reservoir, hollow cylindrical rotary valves arranged in each of said chests, said valves being fixed upon and rotatable by a shaft, gear connection between said valve-shafts and the crank-shaft, said gearing being so arranged and proportioned that said air-valves will make one revolution while the crank-shaft makes two, and the air-valves in each of said chests being in three divisions, a valve in the first of each division in each chest having a port for establishing communication between the air-chamber compartments and the end of the cylinder connected therewith, during the first forward and first return

strokes of each cycle, a valve in the second division in each chest having two ports through one of which communication is established between the cylinder and the external atmosphere during each second return stroke of each cycle, and through the other of which valves communication is established between said cylinder and the atmosphere during the first part of each first return stroke of each cycle, a valve in the third division of said chest having a port through which communication is established between the air-reservoir and the cylinder during the first part of each second forward stroke of each cycle, a valve controlling communication between the cylinder and the external atmosphere, a valve controlling communication between the air reservoir and cylinder, a governor for said valves actuated by the engine, whereby the flow of air between the cylinder and the external atmosphere, and between the reservoir and the cylinder may be regulated and the speed of the piston, while the latter is actuated upon by air-governed, pipe connections between the reservoir and each chamber-compartment, stop-valves for said connections, and means for initially compressing air in said reservoir and air-chamber compartments.

15. The combination in an engine, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber, means for heating the contents of said chamber, valves for establishing communication between said chamber and the cylinder, an air-reservoir, means for compressing air therein and valves for establishing communication between said reservoir and cylinder, said parts being so arranged and connected that air is compressed by the piston from atmospheric pressure and a temperature into said air-chamber, retained and heated in said chamber, and expanded therefrom into said cylinder, and is admitted from said reservoir to said cylinder during the strokes of the cycle, and means for imparting initial movement to said piston.

16. The combination in an engine, of a cylinder, a piston contained therein, a connected crank-shaft, an air-chamber consisting of two compartments, means for heating the contents of said compartments, an air-reservoir, means for compressing air in said reservoir, means for heating the air, valves for establishing communication between said air-chamber compartments and cylinder, and for establishing communication between said reservoir and cylinder, said parts being so arranged and connected that air is compressed by the piston from atmospheric pressure and temperature into said air-chamber compartments, retained and heated in said compartments, and expanded therefrom into said cylinder, and is admitted from said reservoir to said cylinder during the strokes of the cycle, a source of steam-supply, and means for admitting steam to said cylinder to impart initial movement to said piston.

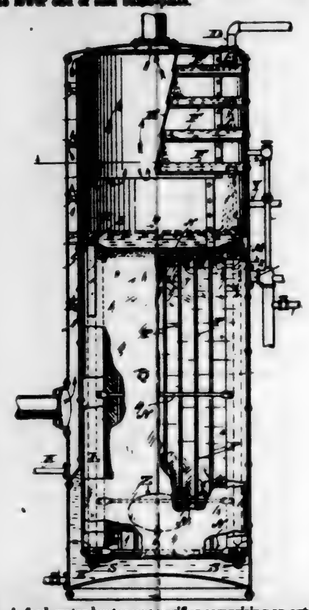
708,028. FEED-WATER HEATER AND PURIFIER. JAMES B. CRAWLEY, Milwaukee, Wis. Filed May 13, 1902. Serial No. 106,827. (No model.)

Claim.—1. A feed-water heater and purifier having an inner filter comprising a skeleton frame consisting of a pair of opposite vertical end-capped channel-plates, horizontal bars connected at their ends to edges of the channel-plates, vertical rods in connection with each series of bars at intervals lengthwise of same; pliable strainer material wrapped on the frame from end to end thereof, and means for clamping the strainer material against said channel-plates of said frame.

2. A feed-water heater and purifier having an inner filter comprising a skeleton frame consisting of a pair of vertical end-capped channel-plates, horizontal bars connected at their ends to edges of the channel-plates, vertical rods in connection with each series of bars at intervals lengthwise of same; pliable strainer material wrapped on the frame from end to end thereof, straps in pairs facing the strainer material parallel to said channel-plates of said frame, bolts extending through each pair of straps above and below the strainer material, and clamp-nuts run on the bolts.

3. A feed-water heater and purifier comprising an outer vertical cylinder having a lower steam-inlet and upper steam-outlet, a shell in connection with the cylinder inside the same forming therewith a steam-space open at the upper end, deflectors fast to said cylinder and shell at intervals within the adjacent steam-space, a drain-pipe for said steam-space, a baffle-plate depending from the upper cylinder-head parallel to the shell within the confines of same, means for collecting and temporarily holding water in suspension within the confines of the baffle-plate, a filter below said baffle-plate, and a feed-pump pipe in connection with the filter.

4. A feed-water heater and purifier comprising an outer vertical cylinder having a lower steam-inlet and upper steam-outlet, a shell in connection with the cylinder inside the same forming therewith a steam-space having deflectors arranged at intervals therein, a drain-pipe for said steam-space, a baffle-plate depending from the upper cylinder-head parallel to the shell within the confines of same, means for collecting and temporarily holding water in suspension within the confines of the baffle-plate, a filter below said baffle-plate, a feed-pump pipe in connection with the filter, and an equalizing-pipe connecting the feed-pump pipe with the cylinder above the lower end of said baffle-plate.



5. A feed-water heater and purifier comprising an outer vertical cylinder having a lower steam-inlet and upper steam-outlet, a shell in connection with the cylinder inside the same forming therewith a steam-space having deflectors arranged at intervals therein, a drain-pipe for said steam-space, a baffle-plate depending from the upper cylinder-head parallel to the shell within the confines of same, pans of gradually-increasing width in descending order supported within the confines of the baffle-plate under a water-inlet, these pans being alternately provided with bottom outlets having upwardly-extending flanges, a filter below said baffle-plate, and a feed-pump pipe in connection with the filter.

708,029. INTERNAL-COMBUSTION ENGINE. RUDOLF DIESEL, Munich, Germany, assignor to Diesel Motor Company of America, New York, N. Y., a Corporation of New York. Filed Jan. 18, 1901. Serial No. 43,602. (No model.)

Claim.—1. In an internal-combustion engine, the combination of a working cylinder, having a valved inlet and a mechanically-controlled

outlet for air or combustible mixture, and means for withdrawing, cooling, and compressing to a high tension a portion of the air or mixture from the working cylinder, substantially as described.

2. In an internal-combustion engine, the combination of a working cylinder having a valved inlet and a mechanically-controlled outlet, for air or combustible mixture, and a fuel-feed valve, and means for withdrawing a portion of the air or combustible mixture from the working cylinder, compressing it to a tension higher than the ultimate tension due to compression in the working cylinder, and delivering the highly-compressed mixture to the fuel-feed valve, substantially as described.

3. In an internal-combustion engine, the combination of a working cylinder having a valved inlet, and a mechanically-controlled outlet, for air or combustible mixture, and a fuel-feed valve; a compressing-pump having an inlet connected to the outlet of the working cylinder and an outlet connected to the fuel-feed valve; and means for operating the compressing-pump, substantially as described.

4. In an internal-combustion engine, the combination of a working cylinder and piston, the working cylinder having a valved inlet, and a mechanically-controlled outlet for air or combustible mixture, a fuel-feed valve, and an exhaust; a source of supply connected to the inlet for air or combustible mixture; a compressing-pump, having an inlet connected to the outlet for air or combustible mixture of the working cylinder, and an outlet connected to the fuel-feed valve; and means for operating the compressing-pump, substantially as described.

5. In an internal-combustion engine, the combination of a working cylinder and piston, the working cylinder having a valved inlet and a mechanically-controlled outlet for air or combustible mixture, a fuel-feed valve, and an exhaust; a source of supply connected to the inlet for air or combustible mixture; a receiver connected with the fuel-feed valve; a compressing-pump, having an inlet connected to the outlet for air or combustible mixture of the working cylinder, and an outlet connected to the receiver; and means for operating the compressing-pump: substantially as described.

6. In an internal-combustion engine, the combination of a working cylinder and piston, the working cylinder having a mechanically-controlled inlet and a valved outlet for air or combustible mixture, a fuel-feed valve, and an exhaust; a source of supply connected to the inlet for air or combustible mixture; a compressing-pump, having an inlet and an outlet; a connection between the inlet of the compressing-pump and the mechanically-controlled outlet of the working cylinder, and a receiver interposed in said connection; a connection between the outlet of the compressing-pump and the fuel-feed valve of the working cylinder, and a receiver interposed in the connection; and means for operating the compressing-pump; substantially as described.

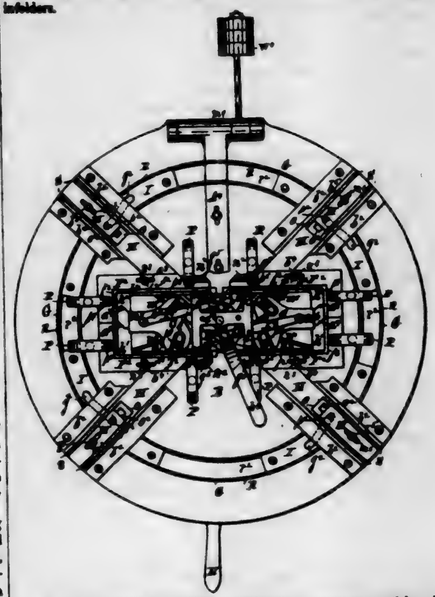
708,080. MACHINE FOR FOLDING COLLAR-BLANKS &c. GARET J. DORNAKDY, Lansingburg, N. Y., assignor to the United Shirt and Collar Company, Troy, N.Y. Filed July 10, 1896. Serial No. 598,471. (No model.)

Claim.—1. In a machine for infolding cuff-blanks or analogous articles, the combination of a support for the blanks, a templet having edge portions adapted to bear directly upon the blanks upon said support and within edge portions of the blanks, infolders constructed and fitted to move inwardly and outwardly whereby edge portions of the blanks may be folded over edge portions of the templet, a slide constructed and fitted to move to and fro, and a plurality of devices, as cams, actuated by the said slide, each device for effecting the inward and outward movements of one or more infolders.

2. In a machine for infolding cuff-blanks or analogous articles, the combination of a support for the blanks, a templet having edge portions adapted to bear directly upon the blanks upon said support, and within edge portions of the blanks, infolders constructed to move inwardly and outwardly whereby the edge portions of the blanks may be folded over the edge portions of the templet, a ring constructed and fitted to slide in bearings located outward of the blanks upon said support, and means intermediate of said ring and of infolders, whereby the said ring may effect the inward and outward movement of infolders.

3. In a machine for infolding cuff-blanks or analogous articles, the combination of a support for the blanks, a templet having edge portions adapted to bear directly upon the blanks upon said support and within edge portions of the blanks, infolders constructed to move inwardly and outwardly whereby the edge portions of the blanks may be folded over the edge portions of the templet, a ring, and a plurality of cams provided in said ring, each for effecting the inward and outward movements of one or more infolders.

4. In a machine for infolding cuff-blanks or analogous articles, the combination of a support for the blanks, a templet having edge portions adapted to bear directly upon the blanks upon said support and within edge portions of the blanks, infolders constructed to move inwardly and outwardly whereby edge portions of the blanks may be folded over edge portions of the templet, a ring constructed and fitted to move to and fro, the said ring located outward of the blanks upon said support, and means actuated by said ring for effecting the inward and outward movements of infolders.



5. In a machine for infolding cuff-blanks or analogous articles, the combination of a support for the blanks, a templet having edge portions adapted to bear directly upon the blanks upon said support, and within edge portions of the blanks, a ring constructed and fitted to slide in suitable bearings provided in said support, infolder-bars constructed and fitted to move inwardly and outwardly, the said bars located above the said sliding ring, cams actuated by said ring for effecting the inward and outward movements of infolder-bars and infolders connected to the infolder-bars.

6. In a machine for infolding cuff-blanks or analogous articles, the combination of a support for the blanks, a templet having expanding and contracting plates, edge portions of which are adapted to bear directly upon the blanks upon said support and within edge portions of the blanks, a ring constructed and fitted to slide in suitable bearings in said support, slide-bars constructed to move inwardly and outwardly, slideways for said slide-bars, the said slideways being connected to the said support above the said sliding ring, cam-surfaces provided upon the said ring, cam-pins downwardly projecting from said slide-bars for engaging with said cam-surfaces, whereby the said ring may effect the inward and outward movements of slide-bars, infolders connected to slide-bars, means for sliding said ring to and fro whereby infolders may be moved inwardly and outwardly to fold edge portions of the blanks over edge portions of said templet, and means whereby the folds of the blanks may be pressed between the support and infolders after withdrawal of the plates of the templet from the folds, and thereby fixed with a sharp fold.

7. In a machine for infolding cuff-blanks or analogous articles, the combination of a support for the blanks, the support provided with an annular bearing, infolders constructed to move inwardly and outwardly whereby edge portions of the blanks may be infolded, a ring constructed and fitted to slide in the bearing in said support, means for oscillating said ring, means intermediate of said ring and of infolders whereby the oscillation of said ring may effect the inward and outward movements of infolders, and means whereby the folds of the blank may be pressed between the support and infolders and before the blanks are taken from the said support, and thereby fixed with a sharp fold.

8. In a machine for infolding cuff-blanks or analogous articles, the combination of a support for the blanks to be infolded, a templet for defining the blanks upon said support, infolders for infolding edge portions of the blanks over edge portions of the templet, bars connected to said infolders constructed and fitted to move inwardly and outwardly, guides for said bars, the said guides being separate from said support and detachable to and detachable from the support, a ring fitted to move to and fro and cams actuated by the ring for effecting the inward and outward movements of the said bars and the infolders connected thereto, the said cams

being separate from the ring and attachable to and detachable from the ring.

9. In a machine for infolding cuff-blanks or analogous articles, the combination of a support for the blanks to be infolded, a templet for defining the blanks upon said support, infolders for infolding edge portions of the blanks over edge portions of the templet, bars connected to said infolders constructed and fitted to move inwardly and outwardly, a part fitted to move to and fro, cams actuated by said part for effecting the inward and outward movements of the bars, and means adjustably connecting the cams and bars, whereby the cams may be longitudinally adjustable upon the bars, so that the infolders may be adapted to the infolding of blanks of varying dimensions.

10. In a machine for infolding cuff-blanks or analogous articles, the combination of a support for the blanks to be infolded, a templet for defining the blanks upon said support, infolders for infolding edge portions of the blanks over edge portions of the templet, bars constructed and fitted to move inwardly and outwardly, means connecting infolders and bars whereby the infolders may be laterally adjustable at the inner ends of the bars, a part fitted to move to and fro, cams actuated by said part for effecting the inward and outward movements of the bars, and means adjustably connecting the cams and bars, whereby the cams may be longitudinally adjustable upon the bars, so that the infolders may be adapted to the infolding of blanks of varying lengths and widths.

11. In a machine for infolding cuff-blanks or analogous articles, the combination of a support for the blanks, a templet having edge portions adapted to bear directly upon the blanks upon said support and within edge portions of the blanks, infolders constructed to move inwardly and outwardly, whereby edge portions of the blanks may be folded over edge portions of the templet, means for effecting the inward and outward movements of said infolders, a part fitted to said machine having upwardly-projecting members, with heads adapted to extend over said infolders when the latter are moved inwardly, and means for depressing said part whereby it may cause the infolders which are moved inwardly to descend toward said support to press and thereby to fix with a sharp fold the infolds of the blanks beneath said infolders.

12. In a machine for infolding cuff-blanks or analogous articles, the combination of a support for the blanks to be infolded, infolders fitted to said support to move inwardly and outwardly whereby the blanks upon said support may be infolded, said infolders being adapted to receive a slight vertical movement sufficient to press with a sharp fold the infolds of the blanks between the said infolders and said support, a treadle, and means intermediate of said treadle and said infolders, whereby the said treadle may effect the vertical movements of the said infolders to press the blanks.

13. In a machine for infolding cuff-blanks or analogous articles, the combination of a bed for supporting the blanks, a ring fitted to the bed to oscillate, means for oscillating said ring, slides fitted to move inwardly and outwardly on said bed, infolders connected to slides, and cams intermediate of said slides and said ring, whereby when the ring is oscillated infolders may be moved inwardly and outwardly.

14. In a machine for infolding cuff-blanks or analogous articles, the combination of a bed, a ring fitted to the bed to oscillate, segments detachably connected to said ring to oscillate therewith and provided with cam-surfaces, inwardly and outwardly moving slides provided with cam-parts for coacting with the cam-surfaces of said segments, infolders connected to said slides and means for oscillating said ring to effect inward and outward movements of infolders.

15. In a machine for infolding cuff-blanks or analogous articles, the combination of a bed, infolders, the bed provided with a circular slideway, a ring capable of sliding in said slideway, the ring provided with a concentric groove, a cam for operating an infolder connected to said ring through the groove therein, and means for moving said ring whereby the infolder may be operated to infold an edge portion of a blank upon said bed.

16. In a machine for loosening the edges of blanks for cuffs or like articles, the combination with a bed having a circular slideway, and also radially-arranged slideways of infolders each provided with a slide-bar arranged in one of said radial slideways, a ring arranged in said circular slideway and provided with a handle by which to be reciprocatingly rotated therein; segments each having a cam-slot and connected to said ring; a slide-pin arranged to make a sliding engagement with the sides of each of the segment-slots, and mounted upon a plate adjustably connected to one of said slide-bars, whereby as said ring is reciprocated in said circular slideway the infolders will be moved inwardly and outwardly substantially as and for the purposes set forth.

17. In a machine for infolding the edges of blanks for cuffs or like articles, the combination with a bed provided with an annular slideway; of a ring having an annular groove, and arranged in said slideway and provided with an operating-handle; radially-arranged slideways formed in said bed; segments each provided with a cam-slot and interchangeably connected to said ring within said annular groove; infolders each having a slide-bar arranged in one of said radial slideways; a slide-pin mounted upon a plate adjustably connected to the outer end of each of said slide-bars, and arranged to make a sliding engagement with the cam-slot of one of the segments whereby as said ring is reciprocatingly rotated the infolders will be moved inwardly and outwardly over the bed, substantially as and for the purposes set forth.

18. The combination with the bed B, having the annular stideway G, and radially-arranged slideways f; of the ring R, having the annular recess r^2, in its upper surface, and provided with an operating-handle H; the segments I, detachably connected to, and arranged within said annular slideway, and each provided with the cam-slot g^2; the slide-bars N, each arranged in one of said radially-arranged slideways, and each provided with a slide-pin p^2, with each of the latter arranged to engage with the slot g^2, of one of the segments; and an infolder F^2, connected to the inner end of each of said slide-bars, constructed and arranged to operate substantially as and for the purposes set forth.

19. In a mechanism for infolding the edges of blanks for cuffs or like articles, the combination with a bed provided with an annular slideway; of a ring constructed with an annular recess and provided with an operating-handle by which to be reciprocatingly rotated in said annular slideway; segments each provided with a cam-slot, and each detachably connected to said ring; slideways radially arranged on said bed; a slide-bar arranged in each of said radial slideways; and each provided with a slide-pin, making a cam or sliding engagement with the cam-slot of one of the segments; an infolder for each of said slide-bars; and means substantially as described for adjustably connecting each of said infolders to one of said slide-bars, constructed and arranged to be operated substantially in the manner as and for the purposes set forth.

20. The combination with the folders F^2, each provided with the slot o^2, and ribbed overhanging side o^3, of the slide-bars N, each provided with a slide-pin p^2, and having a grooved bulge g^3 and each attached to one of said folders by means of the slot o^2, and bolt b^2, and segments each provided with a curved slot adapted to receive the slide-pin of each of said slide-bars, with said segments operated to be reciprocatingly rotated on the machine-bed, substantially as and for the purposes set forth.

21. The combination with the folders F^2, the slide-bars N, each having the recess O, provided with the bottom opening O^2, of the cam-pin plates M, each made with the slot o^3, and having the downwardly-projected cam-pin p^3, the ring R, arranged in the annular recess G, the segmental plates I, each having a cam-pin slot g^3, constructed to connect and be operated substantially in the manner as and for the purposes set forth.

22. The combination with a series of folders arranged upon a bed, each provided with a slide-bar whereby they may be moved inwardly toward or outwardly from each other substantially as described; of presser-arms each having a vertical shank passing down through the bed, and each having a laterally-extended head that will overhang the folders when the latter are moved inwardly; a frame to which the shanks of the presser-arms attach, and a lever operated by a treadle whereby said frame may be drawn downwardly and cause the presser-heads to bear on the folders against the force of a spring, substantially in the manner as and for the purposes set forth.

23. The combination with the bed B, of the frame T^2, the presser-arms P, attached to the latter and upwardly projected therefrom and each provided with an overhanging head p^2, the lever L, provided with a foot-treadle, and connecting-rod; and the folders F^2, arranged on said bed beneath the overhanging heads of the pressers, constructed and arranged to be operated substantially in the manner as and for the purposes set forth.

24. The combination with the frame T^2, of the pressers P, each made with a laterally-extended head p^2, and having a downwardly-projected shank connected to said frame; the folders F^2; the spring S^2, arranged between said frame and the machine-table, and the lever L, provided with a foot-treadle, and connecting-rod constructed and arranged to operate substantially as and for the purposes set forth.

25. The combination with the bed B, provided with slideways S, of the slide-bars N, each connected to a bar n^2, and arranged in one of the slideways; the folders T^2, each connected to one of said bars n^2; the frame T^2; the pressers P, each having the laterally-extended head p^2, and provided with a cheek projected downwardly to connect with a frame beneath the bed, and the lever L, constructed and arranged to be operated substantially in the manner as and for the purposes set forth.

26. The combination with a bed having an annular slideway formed therein; of a ring constructed to be reciprocatingly rotated in said annular slideway; segments each provided with a cam-slot, and attached to said ring; slide-bars each provided with slideways and having a cam-pin plate provided with a cam-pin pintered in one of the segment-slots; a folder attached to each of slide-bars; a blank-holder having a hinged connection with the bed, at one side thereof; pressers each provided with an overhanging head, and connected to a frame beneath the bed; and a lever having a treadle whereby said frame may be moved downwardly with the heads of the pressers bearing upon said folders, substantially in the manner as and for the purposes set forth.

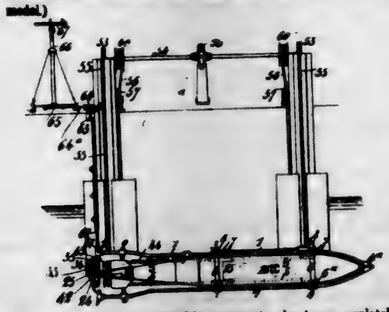
27. In a machine for loosening the edges of blanks for cuffs or like articles, the combination with a bed of a ring provided with a circular slideway formed in said bed, and provided with means to be reciprocatingly rotated therein substantially as described; segments each provided with a cam-slot and constructed to be detachably connected to said ring; infolders each provided with a slide-bar, and a slideway on the bed; a slide-pin mounted on a plate adjustably connected to each of said slide-bars at its outer end and thereat arranged to engage with the sides of one of said cam-slots; and a templet having expanding and indrawing plates upon its under surface, and provided with means whereby it may be operated to descend onto and rise from off said bed, substantially as and for the purposes set forth.

28. In an infolding-machine, the combination with a bed having an annular slideway and radially-arranged slideways; of a ring provided with an annular recess, and a handle by which to be reciprocatingly rotated in said annular slideway; infolders each having a slide-bar arranged in one of said radial slideways, each of said slide-bars having mounted thereon adjustably a plate having at its outer end a slide-pin; segments each provided with a cam-slot adapted to receive one of said slide-pins, said segments being connected in a detachable manner to said ring substantially as and for the purposes set forth.

29. In an infolding-machine, the combination with a bed provided with a circular slideway, and radially-arranged slideways, of a ring provided with a handle by which to be reciprocatingly rotated in said circular slideway; segments each provided with a cam-slot; means substantially as described whereby said segments are detachably connected to said ring; a slide-bar in each of said radial slideways provided with a cam-pin plate having on its outer end a cam-pin arranged to run in one of the said cam-slots; and an infolder mounted on the inner end of each of said slide-bars constructed and arranged to be operated substantially in the manner as and for the purposes set forth.

30. In a machine for infolding blanks for cuffs or like articles, the combination with a bed having an annular slideway and radially-arranged slideways; of a ring provided with a handle by which to be reciprocated in said annular slideway; segments each provided with a cam-slot and connected to said ring; infolders each provided with a slide-bar arranged in one of said radial slideways; a slide-pin mounted upon the outer end of a plate connected to each of said slide-bars, said slide-pins each making a sliding engagement with the slot of one of the segments; and a blank-holder having expanding and indrawing plates on its under surface, and means substantially as described whereby said blank-holder may be operated to descend onto and rise from off said bed, substantially in the manner as, and for the purposes set forth.

708,081. TORPEDO-LAUNCHING APPARATUS. STEPHAN J. J. DZIEWIECKI, Paris, France. Filed Jan. 2, 1902. Serial No. 88,147. (No model.)



Claim.—1. A torpedo-launching apparatus having an unlatching mechanism consisting of a pivoted frame, pivoted claw-arms to engage the torpedo on the outside, a threaded tubular sleeve to engage the central tube of the torpedo and mechanism for releasing said claw-arms, substantially as described.

2. A torpedo-launching apparatus having an unlatching mechanism, comprising pivoted claw-arms having extensions 41, a spring, levers controlled by the spring and connected with the extensions, a lever 24 to hold the claws in latched position and means for latching and unlatching said lever 24, substantially as described.

3. In a torpedo-launching apparatus, an unlatching mechanism consisting of spring-controlled mechanism to normally hold the torpedo and a lever 24 to hold such mechanism latched, in combination with a pointer-bolt, adapted to secure the lever 24, spring mechanism adapted to withdraw the pointer-bolt and means to hold said spring mechanism in check until the torpedo has reached a certain determined position and then release the spring mechanism, substantially as described.

4. An unlatching means for torpedo-launching apparatus, comprising a pivotally-mounted frame, shaped like a figure 3, and a horizontally-pivoted part therein, carrying claw-arms adapted to engage the stern of the torpedo, substantially as described.

5. An unlatching means for torpedo-launching apparatus, comprising a pivotally-mounted frame, a pivoted part in the frame, claw-arms, a cross-head, links connecting the arms and cross-head, a spring to operate the cross-head, a lever pivoted to the lower part of the pivoted part at one end, and passing across and holding down the cross-head, and a pointer-bolt to latch the upper part of the lever in position, as and for the purpose described.

6. An unlatching means for torpedo-launching apparatus, comprising a pivotally-mounted frame, a pivoted part in the frame, claw-arms, a cross-head, links connecting the arms and cross-head, a spring to operate the cross-head, a lever pivoted to the lower part of the pivoted part at one end and passing across and holding down the cross-head, and a pointer-bolt to latch the upper part of the lever in position, a lever secured to the pointer-bolt, fulcrumed to the pivoted part and secured at its other end to a spring-pressed collar, and means for normally holding said spring-pressed collar with its spring compressed and a releasing means, substantially as described.

7. An unlatching means for torpedo-launching apparatus, comprising a pivotally-mounted frame, a pivoted part in the frame, claw-arms, a cross-head, links connecting the arms and cross-head, a spring to operate the cross-head, a lever pivoted to the lower part of the pivoted part at one end and passing across and holding down the cross-head, a pointer-bolt to latch the upper part of the lever in position, a lever secured to the pointer-bolt and to a spring-pressed collar, a lever secured to the collar adapted to control its position and a delivery-lever to operate the collar-operating lever, a sector adjustable in position, normally holding said delivery-lever in check but adapted upon a sufficient movement of the pivoted frame to release said lever, as and for the purpose set forth.

8. A torpedo-unlatching apparatus, comprising a pivotally-mounted frame, a spring-controlled lever for unlatching the torpedo from the frame, said lever having a wire connected with the torpedo-starting mechanism of such strength that upon the release of the latching-lever the wire will be tensioned to throw the torpedo-lever but upon the further movement of the lever the wire will be broken, substantially as described.

9. A torpedo-launching apparatus, comprising a cradle, a pivotally-mounted frame at one end thereof, a sleeve carrying a sector at the upper part of said frame, a pivoted part transversely pivoted in the frame and having upwardly and downwardly depending arms, a spring-controlled cross-head mounted in the pivoted part, claw-arms and links between them and the cross-head, a slot in the cross-head, a lever passing through the slot and pivoted at its lower end to the downwardly-depending arm of the pivoted part, its upper end being latched to the upwardly-extending arm of the pivoted part, a pointer-arm to latch them, a lever for the pointer-arm, spring means to withdraw the pointer-arm, and a delivery-lever to control the said spring means itself controlled by the aforesaid sector, substantially as described.

11. Apparatus for sighting torpedoes, comprising a sector, a shaft to rotate it, a cross-piece 64 to the shaft, a second cross-piece, rods connecting both cross-pieces and a shaft 66 carrying an index and graduated raglet, said shaft being fast to the second cross-head, substantially as described.

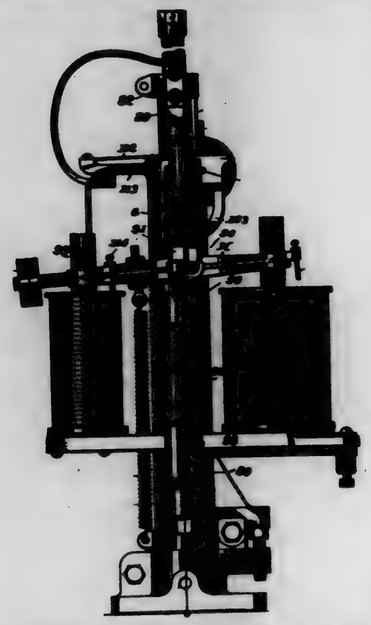
12. Apparatus for launching torpedoes, comprising rails secured to the ship's sides, trolleys mounted on said rails, a cradle mounted on the trolleys, chains secured to the trolleys and mechanism for winding or unwinding said chains, as and for the purposes set forth.

13. Apparatus for launching torpedoes, comprising a cradle, trolleys on which it is mounted, guideways for the trolleys, projections 53 on certain determined points of the guideway and corresponding projections 51 on the trolley, as and for the purpose described.

708,082. ELECTRIC-ARC LAMP. EDGAR A. EDWARDS, Cincinnati, Ohio. Filed Nov. 26, 1900. Serial No. 37,351. (No model.)

Claim.—1. In an electric-arc lamp, the combination with the movable electrode, of a movable support therefor, means for feeding the electrode downward independently of the support, a counterweight balancing the weight of the support and electrode, and means for releasing the connection between the electrode and support at the instant of feeding to

bring the counterweight into active operation to move the support to its higher position independently of the electrode, substantially as set forth.



2. In an electric-arc lamp, the combination with a movable electrode, of a beam, supports for the said electrode connected with the beam at one side of its fulcrum, means for counterbalancing the weight of the parts at the opposite side of the fulcrum, and a rack, pinion, ratchet-wheel and pawl for momentarily releasing the connection between the beam and electrode-support when the electrode has been carried downward to a predetermined extent, substantially as set forth.

3. The combination in an electric lamp, of a beam, a movable electrode, means for supporting the electrode at one side of the fulcrum of the beam, means for momentarily disconnecting the beam and electrode when the latter has been carried downward to a predetermined distance and for thereafter engaging the two when the beam rises, and means for mechanically counterbalancing the weight of the electrode as long as the beam and electrode are in connection, substantially as set forth.

4. The combination in an electric-arc lamp, of a beam, a movable electrode supported by the beam at one side of the fulcrum thereof, a counterweight at the opposite side of the beam maintaining the latter mechanically in equilibrium, solenoids with cores supported by the beam at opposite sides of the fulcrum, and means whereby the connection between the beam and the movable electrode is momentarily released to permit the lifting of the beam and thereafter resumed to maintain the equilibrium of the beam, substantially as set forth.

5. In an electric-arc lamp, the combination with a movable electrode, of a beam supporting the electrode at one side of its fulcrum, a weight counterbalancing the weight of the electrode and means for momentarily releasing the connection between the electrode and beam at the instant of feeding, with the effect of then vibrating the beam by the sole action of the weight, substantially as set forth.

6. In an electric-arc lamp, the combination with a movable electrode, of a support therefor, a beam connected with the support, means for equalizing the weight on opposite sides of the fulcrum of the beam to prevent the vibration of the beam on its fulcrum from the movements of the parts connected with the fulcrum, and means for momentarily releasing the connection between the support and electrode to alter the equilibrium of the beam and bring the weight into action to lift the end of the beam connected with the said support when the electrode has been fed downward to a predetermined extent, substantially as set forth.

7. The combination with the base, operating-solenoids, and movable electrode of an arc-lamp, of connections between the movable electrode and the beam at one side of the fulcrum of the latter, a counterbalance at the opposite side arranged to mechanically counterbalance the beam so long as the beam and electrode are connected, and means for releasing momentarily the said connections when the movable electrode has been carried downward to a predetermined extent, substantially as set forth.

8. The combination with the beam, operating-solenoids, and movable electrode of an arc-lamp, of connections between the movable electrode and the beam at one side of the fulcrum of the latter, a counterbalance at the opposite side, a rack and pinion carried by independent parts of said connections, a ratchet-wheel connected with the pinion, and a pawl connected with a stationary part of the apparatus and to and from which the ratchet-wheel is carried by the vibrations of the beam, substantially as set forth.

9. The combination with the electrodes and operating-solenoids of an arc-lamp, of a beam connected with the movable electrode at one side of its fulcrum, and a weight at the opposite side of the fulcrum arranged to mechanically maintain the beam and parts connected therewith in equilibrium as long as the beam and electrode are in connection, substantially as set forth.

10. The combination with the carbon-feeding mechanism of an electric-arc lamp, of a guide supported on fixed bearings having converging faces constituting a side bearing for the carbon, and a pressure device for maintaining the carbon against said faces, substantially as set forth.

11. The combination with the carbon-feeding mechanism of an electric-arc lamp, of a guide having converging faces constituting a side bearing for the carbon, and a weighted lever for maintaining the carbon against said guide, substantially as set forth.

12. The combination with one electrode of an arc-lamp, of a second electrode consisting of a disk having pointed teeth at the periphery, substantially as set forth.

13. The combination with one electrode of an arc-lamp, of a second electrode consisting of a disk having pointed teeth at the periphery, and means for locking the disk with its active teeth in line with the axis of the opposite electrode, substantially as set forth.

14. The combination with one electrode of an arc-lamp, of a second electrode consisting of a removable disk having pointed teeth at the periphery, substantially as set forth.

15. In an electric-arc lamp, an electrode consisting of a metallic disk adapted to be turned to different positions around its center, and with a series of pointed peripheral projections, substantially as set forth.

16. The combination with the carbon electrode of an arc-lamp, and with its support, of a connection between the support and the electrode constructed to permit the latter to swing laterally in directions at right angles to each other, substantially as set forth.

17. The combination with the carbon electrode of an arc-lamp, and with its support, of a connection, consisting of a flexible blade twisted to present the upper portion at right angles to the lower portion, between the support and the electrode constructed to permit the latter to swing laterally in opposite directions, substantially as set forth.

18. The combination with the carbon electrode of an arc-lamp, and with its support, of a connection, consisting of a blade twisted to present the upper portion at right angles to the lower portion, between the support and the electrode constructed to permit the latter to swing laterally in opposite directions, substantially as set forth.

19. The combination with the carbon electrode of an arc-lamp, and with its support, of a connection, consisting of a blade twisted to present the upper portion at right angles to the lower portion, between the support and the electrode constructed to permit the latter to swing laterally in opposite directions, the connections with the support all being upon a plane running through the fulcrum thereof, substantially as set forth.

20. The combination with the electromagnetic controlling devices of an arc-lamp, of a beam mounted on a fixed support, a pinion connected at one side of the fulcrum of the beam, a rack supported by the said pinion and connected to support the movable electrode, a ratchet-wheel connected with the pinion-shaft, and a pawl engaging the ratchet-wheel and supported by a fixed part of the apparatus, substantially as set forth.

21. The combination with a beam fulcrumed on a fixed support, a movable electrode connected with the beam, feeding mechanism actuated thereby, and a weight to counterbalance the weight of the electrode so long as the electrode is connected therewith, of a balance-spring arranged to move the beam in one direction, and electromagnetic devices arranged to overcome the tension of the spring and move the beam in the other direction, whereby said feeding mechanism is actuated to control the vertical position of the point of the carbon and maintain a substantially constant arc resistance, substantially as set forth.

22. The combination with a beam fulcrumed on a fixed support, a movable electrode connected with the beam, feeding mechanism actuated thereby, and a weight counterbalancing the weight of the electrode when connected with the beam, of electromagnetic devices arranged to control the movements of the beam in opposite directions respectively according to an increase or decrease in the arc resistance from the normal, and an adjustable balance-spring arranged to resist the action of one of said devices and to maintain the beam in a position with the poles of the

arc separated during the discontinuance of the electrical current, substantially as set forth.

23. In an electric-arc lamp, the combination with a movable electrode, of a beam supporting the electrode at one side of its fulcrum, a weight counterbalancing the weight of the electrode, means for momentarily releasing the connection between the electrode and beam at the instant of feeding, with the effect of then vibrating the beam by the sole action of the weight, and means for remaking the connection at a different point as the weighted end of the beam drops, substantially as set forth.

24. The combination in an electric-arc lamp, of a beam, a movable electrode supported thereby on one side of the fulcrum, feed devices, electromagnets connected to vibrate the beam in different directions, to raise and lower the electrode, and a spring arranged to coöperate with the magnet which elevates the electrode, substantially as set forth.

708,033. **DETACHABLE CUSHION-HEEL.** WALTER S. BATES, Webster, Mass., assignor of one-half to A. J. Bates, Webster, Mass. Filed Mar. 11, 1902. Serial No. 97,777. (No model.)

Claim.—1. In a cushion-heel-attaching device, a base-plate having an angular aperture with the edge of the plate at the front and rear end of the aperture turned down to form seats, a plate vulcanized in the heel and having tongues projecting from the inner surface, said plates being adapted to be sprung to cause engagement of the tongues with the base.

2. In a cushion-heel-attaching device, a base-plate secured to the sole of a shoe and having an aperture with the front and rear edge of the aperture turned down to form seats, a plate embedded in the heel and having a front and rear tongue projecting therefrom, the rear tongue being narrower than the front tongue whereby the front tongue will bend slightly to allow rear tongue to seat with the base.

708,084. **HOOK AND EYE.** WILLIAM FLEISCHER, New York, N. Y. Filed Jan. 9, 1902. Serial No. 88,068. (No model.)

Claim.—1. A hook for a hook and eye comprising usual eyelets *a*, *a*, and hook *b*, an arch or projection extending from the back portion of the hook and a looped spring-tongue extending from the eyelets under the extreme end of the hook *b* and into the loop of which the arch or projection normally extends.

2. A hook for a hook and eye formed from a single piece of wire and comprising usual eyelets *a*, *a*, and hook *b*, an arch or projection extending from the back portion of the hook and a looped spring-tongue extending from the eyelets under the extreme end of the hook *b* and into the loop of which the arch or projection normally extends.

3. A hook for a hook and eye comprising usual eyelets *a*, *a*, and hook *b*, an arch or projection extending from the back portion of the hook and a looped spring-tongue extending to a point suitably adjacent the end of the hook *b* and into the loop of which the arch or projection normally extends.

708,035. **SMOKE-CONVEYER.** WILLIAM L. GALE, Louisville, Ky., assignor of one-fourth to Isaac F. Whiteside, Louisville, Ky. Filed Apr. 7, 1902. Serial No. 101,760. (No model.)

Claim.—1. A smoke-conveying tube for railway-trains, comprising a series of adjustable sections each comprising a plurality of telescopic members, springs tending to separate said members, and means for drawing the members together to contract the tube.

2. A smoke-conductor for railway-trains, comprising a plurality of sections independently pivoted on the roof of each car, each of said sections comprising a plurality of yieldably-connected telescopic tubular members.

3. A smoke-conductor for railway-trains, comprising a reversible pivotally-mounted section mounted centrally on each car, independent sections pivotally mounted near the ends of each car, all of said sections being reversible and each comprising a plurality of tubular members having yielding connections.

4. A smoke-conducting tube having telescopic members, springs tending to separate said members, pins carried by the adjacent ends of said members, and adjusting-levers having links embracing said pins.

5. In a device of the class specified, a tube-section rigidly supported on the engine and in communication with the smoke-stack, said section having a top opening, a movable cover for said opening, a telescopic stack member carried by the smoke-stack and adjustable through the opening, and means for adjusting said telescopic member.

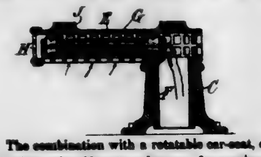
6. In a device of the class specified, a tube carried by the engine and having an open front end, there being an opening in the top of the tube at a point over the top of the smoke-stack, and an adjustable smoke-stack connecting with the tube and movable through said opening.

7. In a device of the class specified, a tube carried by the engine and having an opening above the smoke-stack, a movable cover for said opening, a stack having a section adjustable through said opening, and a cover-holding catch having a portion arranged in the path of movement of the stack.

8. In a device of the class specified, a tube carried by the engine and having a flared front end open for the admission of air and provided with a top opening above the smoke-stack, a hinged cover for said opening, a telescopic smoke-stack adjustable through the opening, a gravity locking-catch arranged in the path of movement of the smoke-stack and serving to keep the cover normally in closed position, and means for raising and lowering the movable portion of the smoke-stack.

9. In a device of the class specified, a smoke-conducting tube pivotally mounted on top of a car, an end rail arranged on a curved line concentric with the pivotal axis of the tube, and a vertically-adjustable supporting-lever carried by and movable on said end rail, substantially as specified.

708,086. **MOUNTING FOR ELECTRIC HEATERS.** EDWARD H. GOLD, New York, N. Y. Filed Oct. 16, 1901. Serial No. 78,287. (No model.)



Claim.—1. The combination with a rotatable car-seat, of means for supporting a heater beneath said seat, and means for moving said heater to maintain it beneath said seat when the latter is moved.

2. The combination with a movable car-seat of means for supporting a heater beneath said seat, and means for moving said heater simultaneously with said seat when the latter is moved.

3. The combination with a movable car-seat of means for supporting a heater beneath said seat, and means for connecting said seat and heater to maintain the latter beneath the seat when the seat is moved.

4. The combination with a movable car-seat of means for supporting a heater beneath said seat, said seat and supporting means being connected to move together.

5. The combination with a seat, of a movable support on which said seat is mounted, and means for carrying a heater on said support.

6. The combination with a plurality of seats, of a single movable support on which said seats are mounted, and means for carrying a heater on said support and in position to extend under each of said seats.

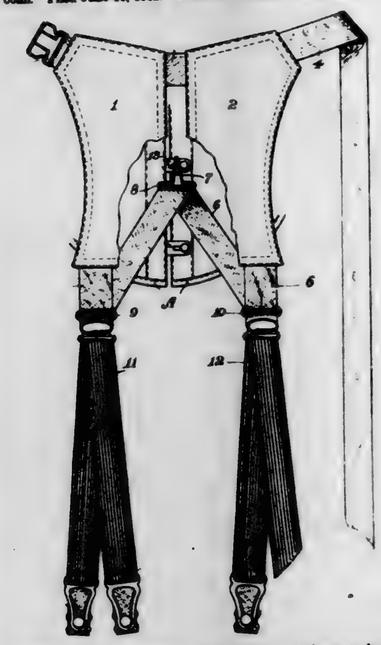
7. The combination with a car-seat, of an oscillating support on which said seat is mounted, and means for carrying a heater on said support.

8. The combination with a seat of a movable support therefor having a tubular body adapted to carry a heater.

9. The combination with a seat of a movable support therefor having a tubular body adapted to carry a heater, and having apertures in the bottom and sides of said body for air circulation.

10. The combination with a seat of a pivoted support therefor comprising a tubular body E provided with a removable plate H and a pivotal extension F, and a fixed support carrying said pivoted support.

708,087. HOSE-SUPPORTER. MYRON B. HARRIGAN, Bridgeport, Conn. Filed June 16, 1902. Serial No. 111,982. (No model.)



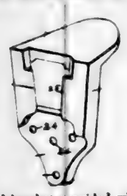
Claim.—1. A hose-supporter comprising a pad element adapted to be secured at its upper corners to the person of the wearer by means of a suitable belt, a webbing having its ends secured to the bottom edge of said pad, a hook device provided at its base with an opening through which the bight of said webbing extends, and stocking-engaging members suspended from said webbing near the points where the latter is secured to the pad element, said hook device being adapted to engage with the corset-clasp, substantially as set forth.

2. A hose-supporter comprising a pad element, means at the upper end of said element for securing the same to the person of the wearer, the webbing having its free ends secured to the bottom edge of the pad element whereby a loop is formed which latter passes loosely through an opening in a hook device adapted to be engaged with the corset-clasp, and stocking-engaging members having links at their upper extremities through which links said webbing is passed loosely immediately below the bottom edge of the pad, substantially as set forth.

708,088. VISE AND BRACKET. CHARLES B. HARPER, Marshalltown, Iowa. Filed Jan. 13, 1902. Serial No. 89,626. (No model.)

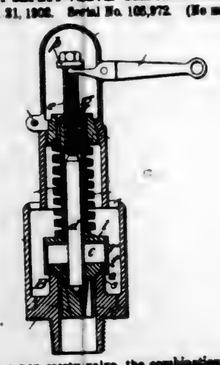
Claim.—1. An elbow-shaped bracket provided with an angular aperture in its upright portion and the vertical edges of the aperture beveled and the upper ends of the flanges adapted to aid in supporting a vise and the lower end portion provided with bolt-holes and the horizontal portion of the bracket adapted to overlie the top of a work-bench, in the manner set forth for the purposes stated.

2. An elbow-shaped bracket provided with an angular aperture in its upright portion and the vertical edges of the aperture beveled and the upper ends of the flanges adapted to aid in supporting a vise and the lower end portion provided with bolt-holes and the horizontal portion of the bracket adapted to overlie the top of a work-bench, a vise having an aperture in its rear jaw and a recess for a nut around said aperture and dovetail tenons on the face of the jaw to engage the beveled edges at the sides of the aperture in the bracket, in the manner set forth for the purposes stated.



3. An elbow-shaped bracket provided with an angular aperture in its upright portion and the vertical edges of the aperture beveled and the upper ends of the flanges adapted to aid in supporting a vise and the lower end portion provided with bolt-holes and the horizontal portion of the bracket adapted to overlie the top of a work-bench, a vise having an aperture in its rear jaw for the passage of the screw for operating the hinged jaw and a recess for a nut around said aperture and dovetail tenons on the face of the jaw to engage the beveled edges at the sides of the aperture in the bracket, arranged and combined with a work-bench in the manner set forth for the purposes stated.

708,089. POP SAFETY-VALVE. BERNHARD HELLWIG, Cincinnati, Ohio. Filed Apr. 21, 1902. Serial No. 103,972. (No model.)



Claim.—1. In a pop safety-valve, the combination, with the valve and its seat, a spring for holding the valve closed and a spindle-socket surrounding the valve-spindle against which said spring acts, of a cylindrical pop-lift secured to the spindle-socket and embracing the upper edge of the valve-seat base, to form an annular chamber of a greater area than the valve to insure a pop action therefor, substantially as shown and described.

2. In a pop safety-valve, the combination, with the valve and its seat, of a casing for same, a regulator-ring screwed into the upper portion of said casing, a valve-spindle and regulating-screw therefor, and a spindle-socket with coiled spring bearing between the spindle-socket and the regulator-ring, substantially as shown and described.

3. In a pop safety-valve, the combination with the valve and its seat, of a casing for same, a regulator-ring screwed into the upper portion of said casing, a valve-spindle and regulating-screw therefor, a spindle-socket carrying a cylindrical pop-lift at its lower end to embrace the upper edge of the valve-seat base, with a coiled spring bearing between the spindle-socket and regulator-ring, substantially as shown and described.

708,040. FIRE-LADDER. SAMUEL B. HEMÉY, Washington, D. C. Filed Oct. 25, 1901. Serial No. 79,976. (No model.)

Claim.—1. The combination of a ladder having a sill, a nut carried by the sill and located between the side bars of said ladder, and a screw passing through the nut and the nut being fixed relatively to the screw against movement in the direction of the length of said screw.

2. The combination of a ladder having a sill, a nut carried by the sill substantially centrally thereof, a screw passing through said nut and said nut being held against movement relatively to the screw in the direction of the length of said screw, and a base-piece adapted to rest upon the ground, and connected to said screw.

3. The combination of a ladder having a sill, a nut carried by the sill substantially centrally thereof, a screw passing through the nut and the latter being held against movement relatively to the screw, in the direction of the length of said screw, and a base-piece swiveled to the screw.

4. The combination of a ladder having a sill provided with a seat on its under side and having a fixed nut, a screw passing through said nut, a base-piece swiveled to the lower end of the screw and arranged to fit in said seat, and means carried by the screw for rotating the same.

5. The combination of a ladder having a sill provided with a seat on its under side and having a fixed nut, a screw passing through said nut, and a base-piece connected to the screw and arranged to fit completely in said seat.

708,041. SAFE OR VAULT DOOR. HENRY D. HIBBARD, Plainfield, N. J., assignor to Hibbard-Rodman-Ely Safe Company, borough of Manhattan, New York, N. Y., a Corporation of New Jersey. Filed Mar. 11, 1902. Serial No. 97,883. (No model.)

Claim.—1. A safe or vault door comprising a body having a rearwardly-extending flange integral therewith provided with bolt-openings for the passage of bolts; bolt mechanism carried by such door; and a filling-plate located between the bolt mechanism and said body and receiving the strain of said bolts when in their protracted positions, whereby such bolts assist in maintaining said plate in position.

2. A safe or vault door comprising a body having a rearwardly-extending integral flange provided with bolt-openings; bolts working in such openings; a filling-plate located between such bolts and said body and having bearing-surfaces for the bolts and receiving the strain of such bolts when in their protracted positions whereby such bolts assist in maintaining it in position, said plate also having a centrally-located boss for the engagement of the inner ends of the bolts therewith.

3. A safe or vault door comprising a body having a rearwardly-extending integral flange provided with bolt-openings; bolts working in such openings; a filling-plate located between such bolts and said body and having bearing-surfaces for the bolts and receiving the strain of such bolts when in their protracted positions whereby such bolts assist in maintaining it in position, said plate also having a centrally-located boss for the engagement of the inner ends of the bolts therewith, said filling-plate and body constructed to form with the door-body a chamber for the reception of non-conducting material.

4. A safe or vault door comprising a body having a rearwardly-extending flange provided with bolt-openings; bolts working therein; and a filling-plate located between said bolts and said body and having a centrally-located boss coöperating with the inner ends of the bolts when in their protracted positions to prevent the withdrawal thereof except in the proper manner.

5. A safe or vault door comprising a body having a rearwardly-extending flange formed of unmachinable metal and a filling-plate wedged in position in the rear of said body.

6. A safe or vault door comprising a body having a rearwardly-extending flange formed of unmachinable metal and a filling-plate wedged in position in the rear of said body and constructed to form a chamber for the reception of non-conducting material.

7. A safe or vault door comprising a body having a rearwardly-extending flange; a filling member located in the rear of said body and interiorly of said flange; and a sectional wedge securing said member in position.

8. A safe or vault door comprising a body having a rearwardly-extending flange; a filling-plate bolted centrally thereof to said door-body and wedged at its periphery interiorly of said flange.

9. A safe or vault door comprising a body having a rearwardly-extending flange; a filling-plate connected centrally thereof to said door-body and wedged at its periphery interiorly of said flange, and constructed to form with the door-body a chamber for the reception of non-conducting material.

10. A safe or vault door comprising a body having an integral flange; a filling-plate located in the rear of said body and interiorly of said flange and connected centrally thereof to the door-body; and a sectional wedge located at the periphery of said plate to assist in securing it in position.

11. A safe or vault door comprising a body having an integral flange; a filling-plate located in the rear of said body and interiorly of said flange and connected centrally thereof to the door-body; a sectional wedge located at the periphery of said plate to assist in securing it in position relatively to the door, and bolts located in position to also assist in maintaining the plate in position when such bolts are protracted.

12. A safe or vault door comprising a body having an integral flange; a filling-plate located in the rear of said body and interiorly of said flange and connected centrally thereof to the door; a sectional wedge located at the periphery of said plate to assist in securing it in position relatively to the door; and bolts located in position to assist in maintaining said plate in position when such bolts are protracted, said plate having a centrally-located boss for the engagement of the inner ends of the bolts therewith to prevent the withdrawal thereof except in the proper manner.

13. A safe or vault door comprising a body having a rearwardly-extending integral flange provided with bolt-openings; a filling-plate located in the rear of said body and interiorly of said flange and secured to said door centrally thereof; sectional wedges located at the periphery of said plate to assist in maintaining it in position, the strain of the bolts when in their protracted position being received by said plate, thereby to assist in maintaining the same in position, said plate having a centrally-located boss coöperating with the inner ends of the bolts and constructed to form with the door-body a chamber for the reception of non-conducting material, and means for swinging said bolts during their longitudinal movement.

14. A safe or vault door comprising a body having a rearwardly-extending tapered flange, provided with bolt-openings; bolts working in said openings; and a plate located interiorly of said flange and between the bolts and the door-body; the organization being such that as the door is forced into the door-opening of the safe or vault body by the bolts, the strain of such bolts is received by the plate, whereby the same is forced into more intimate engagement with the door-body.

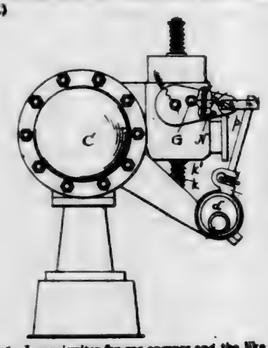
15. A safe or vault door comprising a body having a rearwardly-extending tapered flange provided with bolt-openings, bolts working in said openings, and means free of integral connection with the door and located interiorly of said flange and between the bolts and the door-body to receive the strain of the bolts as they force the door into the door-opening of the safe or vault body, whereby such strain-receiving means is forced toward the body of the door, the bolts thus being more firmly wedged in their bolting position.

16. A safe or vault member comprising an outer member and an inner member secured to each other centrally thereof and constructed one with a flange to form an intermediate chamber.

17. A safe or vault member comprising an outer member and an inner member in engagement with each other centrally thereof and constructed one with a flange to form an intermediate chamber.

18. A safe or vault door comprising a body having a rearwardly-extending flange, and a filling-plate in engagement with said body centrally thereof and wedged at its periphery interiorly of said flange.

708,042. SPARKING IGNITER FOR EXPLOSIVE-ENGINES. JOHN B. HINES, Detroit, Mich. Filed Nov. 9, 1901. Serial No. 81,699. (No model.)



Claim.—1. In an igniter for gas-engines and the like, the combination of a fixed and a movable electrode, a rock-shaft, and an arm secured thereto carrying the movable electrode in a position adapting it to be moved into contact with the fixed electrode, with an operating-arm se-

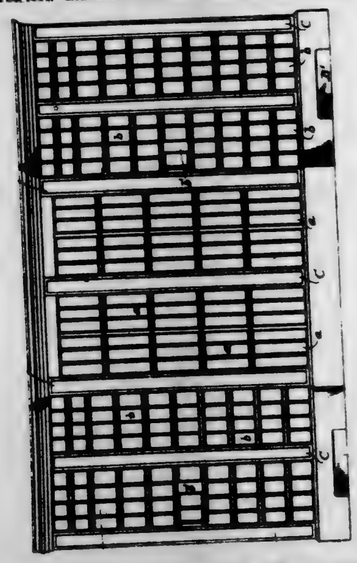
secured to said rock-shaft, and two independently-pivoted arms engaging with opposite sides of said operating-arm, a spring connected with the two outer arms and acting to draw them toward each other, and a movable tripping device engaging with one of said outer arms and adapted to move it upward and then release it to the action of said spring, substantially as and for the purpose specified.

2. In an igniter for gas-engines and the like, the combination of a fixed and a movable electrode, a rock-shaft, and an arm secured thereto carrying the movable electrode in a position adapting it to be moved into contact with the fixed electrode, with an operating-arm secured to said rock-shaft, two independently-pivoted arms engaging with opposite sides of said operating-arm, said three arms having flat contacting surfaces, a spring connected with the two outer arms and acting to draw them toward each other, and a movable tripping device engaging with one of said outer arms and adapted to move it upward and then release it to the action of said spring, substantially as and for the purpose specified.

3. In an igniter for gas-engines and the like, the combination of a fixed and a movable electrode, a rock-shaft, and an arm secured thereto carrying the movable electrode in a position adapting it to be moved into contact with the fixed electrode, with an operating-arm secured to said rock-shaft, two independently-pivoted arms engaging with opposite sides of said operating-arm, a spring connected with the two outer arms and acting to draw them toward each other, a rocking lever pivoted to a fixed support, a tripping-finger pivoted to said lever and engaging with one of said spring-connected arms, a constantly-driven shaft, an eccentric connected thereto, a connecting-rod transmitting motion from said eccentric to said rocking lever, and means for lengthening and shortening said connecting-rod, substantially as and for the purpose specified.

4. In an igniter for gas-engines and the like, the combination of a fixed and a movable electrode, a rock-shaft, and an arm secured thereto carrying the movable electrode in a position adapting it to be moved into contact with the fixed electrode, with an operating-arm, an arm loosely pivoted on the same rock-shaft and lying above and in contact with said operating-arm, an arm pivoted on a different axis and lying below and in contact with said operating-arm, a contractile coil-spring connected with the two outer arms and acting to draw them toward each other and into contact with the intermediate operating-arm, and a tripping device for actuating the upper one of said arms, substantially as and for the purpose specified.

708,048. COMBINATION-SIDEBOARD. JOHN T. HICKS, Boston, Mass., assignor to Hotel Security Checking Company, Portland, Me.; Boston, Mass., and New York, N. Y., a Corporation of Maine. Filed Jan. 30, 1901. Renewed Oct. 26, 1901. Serial No. 80,119. (No model.)

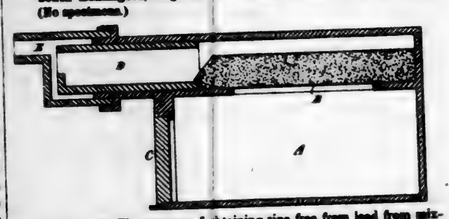


Claim.—1. In a sideboard, the combination with a main central section, having spaces for the reception of bottles from which liquors are being dispensed, and a refrigerating-space for the reception of bottled goods, of wings or side sections for holding clean glassware and the like, said main and side sections being furnished with front and rear slides, whereby the contents of the several spaces or chambers can be readily approached, substantially as described.

2. In a sideboard, the combination of the central section and the side or wing sections, all of which are provided at front and rear with series of slides, a series of mirrors on the front of the sideboard behind which mirrors the said slides may be pushed individually, as described, a series of open-work shelves in the wing-sections, a series of open-work shelves in the main section, provided with partial partitions, means in the front portions of the main section for closing temporarily the mouths of the bottles therein from which drinks are being dispensed by the bartender, an ice-chest for keeping cool the contents of the main section, and a locking device for the slides, substantially as described.

3. In a sideboard, the combination with a main section having spaces for the reception of bottles from which liquors are being dispensed and a refrigerating-space for the reception of bottled goods, means for closing temporarily the mouths of the bottles from which drinks are being dispensed, a guide for keeping said bottles in position, front and rear slides for enabling the contents of the spaces or chambers to be readily approached at any desired point.

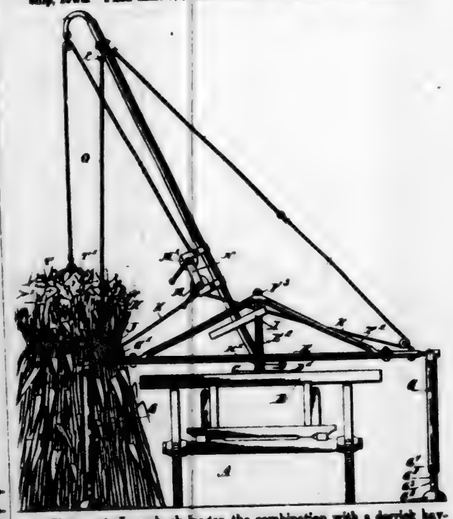
708,044. PROCESS OF OBTAINING ZINC. EVAN H. HOPKINS, South Kensington, England. Filed July 1, 1901. Serial No. 66,721. (No specimens.)



Claim.—1. The process of obtaining zinc free from lead from mixtures of the oxids of zinc and lead which consists in heating carbon to incandescence, heating the oxids mixed with carbonaceous materials in a closed retort and passing the products of distillation upward through the incandescent carbon.

2. The process of obtaining zinc free from lead from ores containing lead and zinc consisting in heating carbon to incandescence, roasting lead-zinc sulfid ores, mixing the metallic oxids thus obtained with carbonaceous material, heating the same in a closed retort and passing the products of distillation upward through carbon heated to incandescence.

708,045. SHOCK-LOADER. AARON C. HOOTSMILL, Tama Township, Iowa. Filed Mar. 3, 1902. Serial No. 96,849. (No model.)



Claim.—1. In a shock-loader, the combination with a derrick having a mast-tilting truss mounted transverse to the loading-rack, and a rock to support the same, of end supports for said truss adapted to rest on the ground, substantially as described.

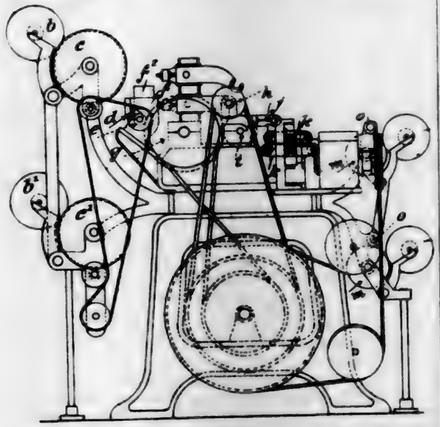
2. In a shock-loader, the combination with a derrick-truss and a central support therefor, substantially as described, of adjustable end supports for the truss, with bread feet or bases to rest on the ground, substantially as set forth.

3. In a shock-loader, the combination of a tilting mast, a truss adjacent to the foot thereof, sheaves near the ends of the truss, a windlass mounted on the mast, and a guy-rope passing around the windlass and sheaves and connecting with the mast near its upper end.

4. In a shock-loader, the combination of a tilting mast, a truss adjacent to the foot thereof, means substantially as described for tilting the mast, a gooseneck mounted to turn in the top of the mast, a sheave depending therefrom, a lifting-windlass secured to the mast, a grab for holding the shock and a rope running over said sheave and attached at one end to the grab and at the other end to the windlass, substantially as described.

5. In a shock-loader, the combination of a rail adapted to rest on a wagon-rack, a derrick mounted to slide endwise thereon, said derrick comprising a rail mounted above and parallel with the longer rail, with suitable bearings to connect them slidably, a mast and brace therefor mounted pivotally on the upper rail, a truss attached to said upper rail and transverse thereto, a stirrup embracing the mast and center post of the truss, and means substantially as described for tilting the mast.

708,046. CARDING-MACHINE. WILLIAM H. HOYLE and THOMAS BARKER, Bolton, England. Filed Mar. 26, 1902. Serial No. 100,434. (No model.)



Claim.—1. In an apparatus for the purpose described, the combination with the carding-cylinder, of an elongated feed-roller in proximity thereto, and a plurality of independently-movable section-feed devices arranged in juxtaposition to said feed-roller, substantially as described.

2. In combination, in an apparatus for recondensing condenser-yarn or the like, the combination with the plurality of bobbins, of a feed-roller, a plurality of section-feed devices in juxtaposition to said roller, a main cylinder *g*, a doffer *i*, and doffing-comb *j*, and a "fancy-roller" *h* and rubbers *k*, *k*, for rubbing the sections of yarn, substantially as described.

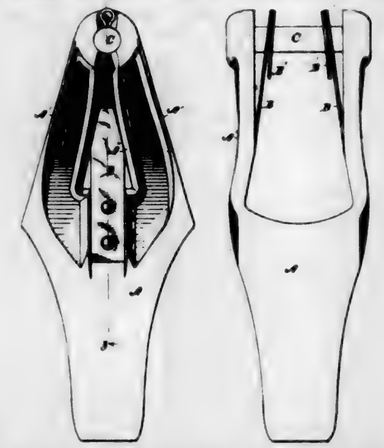
3. In combination in an apparatus such as is herein described a plurality of bobbins for holding condenser-yarn, means for withdrawing said yarn, a sectional feed, comprising an elongated roller, a plurality of independently-movable presser devices cooperating therewith, a main carding-cylinder a doffer and doffing-comb, rubbers for rubbing the yarn and means for batching the recondensed yarn substantially as described.

4. In a machine of the class described, the combination with the carding-cylinder *g*, of a single elongated feed-roller *c* in proximity thereto, a feed-plate above the feed-roller having a plurality of compartments, and a plurality of blocks seated in said compartments and having guiding-grooves in their lower portions, substantially as described.

708,047. CAR-WHEEL. BENJAMIN S. JEFFERSON, Athens, Ohio, assignor to Athens Foundry & Machine Co., Athens, Ohio. Filed May 5, 1902. Serial No. 106,051. (No model.)

Claim.—In a car-wheel, a rim, a hub, tangentially disposed and curved spokes between the hub and rim, the hub comprising inner and outer shells joined at their inner end portions, said shells forming an oil-chamber, braces of approximately T form interposed between the inner and outer shells and having their head portions disposed at the outer end portion of the inner shell and their cheek portions extending horizontally and longitudinally bracing the shells, a wall closing the outer and open end of the oil-chamber, said wall being integral with the outer shell and having a tapering oil-hole centrally therethrough, an opening in the outer shell for insertion and extraction of the cutter-pin, said opening being normally closed, there being spirally-formed grooves or channels provided upon the wear-surface of the inner shell for the purpose set forth, the whole structure being of integral formation, substantially as set forth.

708,048. TROLLEY HARP OR FORK. OTTO P. JOHNSON and FRED P. CROCKETT, Kalamazoo, Mich., assignors to the Star Brass Works, Kalamazoo, Mich. Filed Apr. 28, 1900. Serial No. 14,771. (No model.)



Claim.—1. The combination of the harp A divided into forks above, being suitably ribbed at A', A' to protect the parts; a journal-pin C retained within the harp by suitable means; a spring B secured to the outside of said harp and extending upwardly through suitable apertures in the same within the forks above and being formed forked at its upper end to embrace the pin C; and a contact-washer B' with a projecting portion *c'* to engage within the forks of the spring, all constructed substantially as described for the purpose specified.

2. The combination of the harp A divided into forks above; a journal-pin extending through said forks to carry the trolley-wheel; a spring secured to said harp and extending upwardly inside of the fork, being forked at its upper end to embrace the said pin; and a washer with a suitable projection to engage between the forks of the spring and to contact with the side of the trolley-wheel, counting for the purpose specified.

3. In a contact device for trolley-harps, a spring forked at its upper end, and a washer having suitable projections to engage between the forks of said spring to contact with a trolley-wheel, for the purpose specified.

4. A trolley-harp divided into forks above; a spring-brush forked at its upper end; and a washer, having a suitable projection to engage between the forks of the said spring-brush to contact with a trolley-wheel, counting for the purpose specified.

5. The combination of a harp divided into forks above; a spring secured to the outside of said harp and extending upwardly through suitable apertures, and fulcrumed on the inner side of the same, for the purpose specified.

708,049. TABLE-SPREAD SUPPORT. DAVID C. JORDAN, David City, Nebr. Filed June 6, 1901. Serial No. 63,431. (No model.)

Claim.—The arched cover-supporting frame designed to be arranged over a dish or dishes and comprising a series of laterally-adjustable foldable arms curved longitudinally and provided at their upper ends with vertical pivots, the upper and lower clamping-plates arranged above and below the upper ends of the arms and provided with perforations, the perforation of the lower plate being threaded and one of said plates being provided with openings to receive the said pivots, a screw extending through the perforations of the plates and engaging the screw-threads of the lower plate, and a coiled spring arranged on the upper portion of the screw and forming a grip or handle and engaging the screw and the upper plate, whereby the latter is yieldingly held in engagement with the arms to permit the same to be adjusted laterally and to be folded together, substantially as described.

708,050. MILK-DIPPER. FRANCIS J. KEE, Watervliet, N. Y. Filed Oct. 26, 1901. Serial No. 80,123. (No model.)

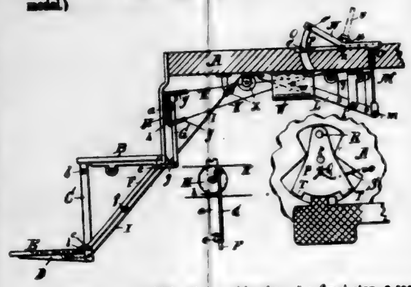
Claim.—1. A device of the kind described comprising a dipper or cup and a handle having an opening near its lower end, a cover having a projection extending through said opening and pivoted therein, and a spring-actuated rod connected to the projection and carried by the handle, and means for operating the spring-actuated rod, substantially as described.

2. A device of the kind described comprising a dipper and handle, said handle having an opening near the bottom, the cover having a rear projection extending through the opening and pivoted therein, the rod connected thereto, the spring-actuated lever pivoted upon the handle and pivotally connected to the said rod, substantially as described.

3. A device of the kind described, comprising a cup or dipper, a handle attached thereto, the pivoted cover having a groove provided with a packing-ring, said cover having a rearwardly-projecting extension, a rod attached to said extension, the event-lever pivoted to the handle, the links for connecting the levers and rod, a spring attached to the said rod at its upper end, the opposite end of said spring being connected to the handle and the supplemental springs attached at one end to the handle and at the other end to the rear extension adjacent to the lower end of the handle, substantially as described.

4. The combination with a cup or dipper, having a curved plate arranged upon the inside thereof, of a pivoted cover, having a groove, provided with a packing-ring adapted to fit upon the rim of the cup, said cover also having a restraint-groove provided with a packing and adapted to fit the top of the curved plate.

708,051. STEP FOR STREET-CARS OR OTHER VEHICLES. CHARLES W. KEYLER and ADAM MATZ, Cincinnati, Ohio; said Keyler assignor to said Matz. Filed Apr. 1, 1901. Serial No. 53,967. (No model.)



Claim.—1. In a vehicle, the combination of a fixed step, a second step movably hung thereto, and projecting below and horizontally outward therefrom; means for rigidly holding and locking said lower suspended step in said horizontal position; means for unlocking the same; means for pulling it back and folding it up horizontally under the fixed step; means for holding said movable step locked in said last-named position; means for unlocking the same therefrom, and means for lowering said adjustable step into its former lower horizontally-extended position, substantially as shown and described.

2. In a vehicle, the combination of a fixed step, a second step movably hung thereto, and projecting below and horizontally outward therefrom, knuckle-jointed braces for rigidly holding and locking the said lower suspended step in said horizontal position; means for making and breaking said braces at their knuckle-joints; means for pulling said movable step back and folding it up horizontally under said fixed step; means for holding said movable step locked in said last-named position; means for unlocking the same therefrom, and means for lowering said adjustable step into its former lower horizontally-extended position, substantially as shown and described.

3. In a vehicle, the combination of the fixed step B, a second step E, movably hung thereto and projecting below and horizontally outward therefrom, knuckle-jointed braces F, (for rigidly holding and locking said lower suspended step in said horizontal position) provided with arms *g*, means for raising or lowering said arms *g* as desired, thereby making or breaking said braces at their knuckle-joints; means for pulling said movable step back into a vertical position under said fixed step; means for holding the same locked in said vertical position; means for unlocking the same therefrom, and means for lowering said adjustable step into its former lower horizontally-extended position, substantially as shown and described.

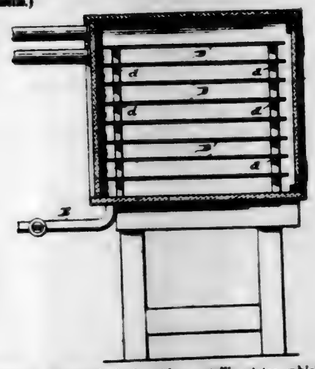
4. In a vehicle, the combination of the fixed step B, a second step E, movably hung thereto and projecting below and horizontally outward therefrom, knuckle-jointed braces F, (for rigidly holding and locking said lower suspended step in said horizontal position) provided with arms *g*; means for raising or lowering said arms *g*, as desired, thereby breaking said braces at their knuckle-joints; means for pulling said movable step back and folding it up horizontally under said fixed step; means for holding the same locked in said vertical position; means for unlocking the same therefrom, and means for lowering said adjustable step into its former lower horizontally-extended position, substantially as shown and described.

5. In a vehicle, the combination of the fixed step B, a second step E, movably hung thereto, and projecting below and horizontally outward therefrom, knuckle-jointed braces F, (for rigidly holding and locking said lower suspended step in said horizontal position) provided with arms *g*, pulleys H, suitably journaled to the brackets *a*, to which pulleys are eccentrically journaled the ends of pitman-rods G, the other ends of which are pivoted to the ends of the arms *g*, means for rotating said pulleys H, means for pulling said movable step back into a vertical position under said fixed step; means for holding the same locked in said vertical position; means for unlocking the same therefrom, and means for lowering said adjustable step into its former lower horizontally-extended position, substantially as shown and described.

6. In a vehicle, the combination of the fixed step B, a second step E, movably hung thereto and projecting below and horizontally outward therefrom, knuckle-jointed braces F, (for rigidly holding and locking said lower suspended step in said horizontal position) provided with arms *g*, pulleys H, suitably journaled to the brackets *a*, to which pulleys are eccentrically journaled the ends of pitman-rods G, the other ends of which are pivoted to the ends of the arms *g*, means for rotating said pulleys H, means for pulling said movable step back and folding it up horizontally under said fixed step; means for holding the same locked in said vertical position; means for unlocking the same therefrom, and means for lowering said adjustable step into its former lower horizontally-extended position, substantially as shown and described.

7. In a vehicle, the combination of the fixed step B, a second step E, movably hung thereto, and projecting below and horizontally outward therefrom, knuckle-jointed braces F, (for rigidly holding and locking said lower suspended step in said horizontal position) provided with arms *g*, pulleys H, pitman-rods G, cables I, cables K, hangers C, brackets D, pulleys *x*, pulleys *y*, lever L, pitman-rod M, treadle N, segment O, latch P, spring S, and adjustable weight W, substantially as shown and described.

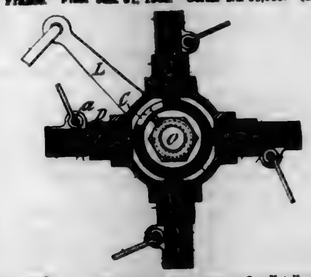
708,052. STCHING DEVICE. ISIDOR KITSEE, Philadelphia, Pa. Filed Sept. 16, 1899. Renewed Feb. 3, 1902. Serial No. 93,262. (No specimens.)



Claim.—1. The method of etching metallic plates, which consists in subjecting said plates simultaneously to the action of an active gas or vapor and to the action of steam.

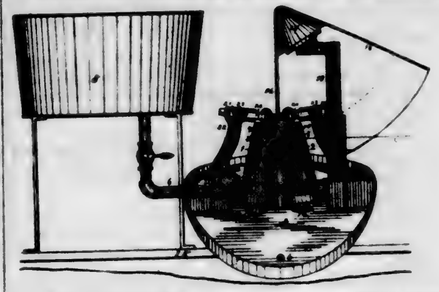
2. The method of etching, which consists in bringing in contact the parts of the plates to be etched, simultaneously with two agents each from a separate source, one agent in a gaseous form, capable of combining with the metal in the presence of moisture, the second a passive agent, capable of imparting to the first agent the moisture required.

708,053. APPARATUS FOR DISTRIBUTING THE PRIMARY CURRENT FOR ELECTRIC IGNITION BY COILS AND IGNITERS IN EXPLOSIVE-ENGINES. ARTHUR C. KRAKE, Paris, France, assignor to Société Anonyme des Anciens Etablissements Panhard et Levassor, Paris, France. Filed Jan. 31, 1902. Serial No. 91,969. (No model.)



Claim.—In a gas-engine or the like, means for distributing a current to a plurality of igniters comprising brushes connected separately to said igniters, a terminal, means for revolving said terminal to contact with said brushes in succession, tubes carrying said brushes, springs in the outer ends of said tubes, pressing said brushes inward, clamp-caps closing the outer ends of said tubes, and conducting-wires attached to said clamp-caps.

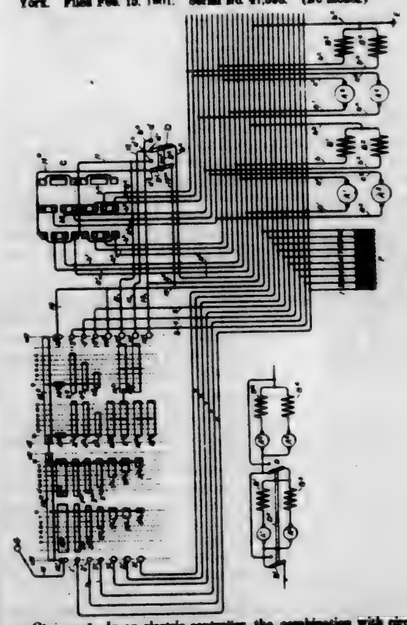
708,054. HAT-STIFFENING MACHINE. NATHANIEL LEVESQUE, Fall River, Mass., assignor of one-half to James Marshall and Brothers, Fall River, Mass. Filed Apr. 26, 1902. Serial No. 104,879. (No model.)



Claim.—1. The combination in a hat-stiffening machine, of a pair of vertically-mounted rolls, means for applying stiffening material to a hat-body, of an adjustable scraper-bar supported from a fixed part of the machine adjacent to the top of one of the rolls, said scraper-bar contacting with the hat-body to remove the surplus stiffening deposited upon the hat-body from the top downwardly, substantially as described and shown.

2. The combination in a hat-stiffening machine, of a pair of vertically-mounted rolls, means for applying stiffening material to a hat-body, of a pair of adjustable scraper-bars supported from fixed parts of the machine, the one bar within and the other without the hat-body, said scraper-bars contacting with the hat-body upon each side of it simultaneously to remove the surplus stiffening deposited upon the hat-body, substantially as described and shown.

708,055. ELECTRIC CONTROLLER. JOHN B. LIEB, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Feb. 15, 1901. Serial No. 47,398. (No model.)



Claim.—1. In an electric controller, the combination with circuit-controlling devices for two pairs of parallel-connected motors, of a switch

comprising two blades, and connections whereby one pair of motors will be cut out when one blade is thrown and the other pair when both blades are thrown.

2. In an electric controller, the combination with circuit-controlling devices for a plurality of motors, of a cut-out switch for said motors comprising two blades, and means for permitting an independent movement of each blade in one direction only.

3. In an electric controller, the combination with circuit-controlling devices for a plurality of motors, of a cut-out switch for said motors comprising two blades, and connections permitting each blade to move independently in one direction, but compelling one to actuate the other when moved in the other direction.

4. In an electric controller, the combination with circuit-controlling devices for a plurality of motors, of a cut-out switch for said motors comprising two blades, one capable of independent movement in one direction and the other in the opposite direction, and means for compelling each to actuate the other when moved in the reverse direction.

5. In an electric controller, the combination with circuit-controlling devices for a plurality of motors, of a cut-out switch comprising two blades pivoted to move in parallel planes, and a handle on each blade projecting into the path of movement of the other handle.

6. In an electric controller, the combination of a circuit-controlling device for a plurality of motors, of a cut-out switch comprising two blades pivoted to move in parallel planes and overlapping handles carried by said blades.

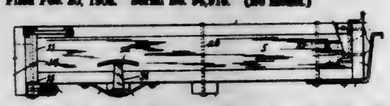
7. In an electric controller, the combination with a series-parallel contact-cylinder having a lug on its shaft, of a hooked lever adjacent to the shaft, a cut-out switch having two parallel blades independently movable, a link connecting one of said blades with the lever, and overlapping handles on the blades.

8. In an electric controller, means for electrically connecting two contact-cylinders, comprising electrically-connected collars having a sliding fit on said cylinders.

9. In an electric controller, means for electrically connecting two parallel contact-cylinders, comprising a divided collar on each cylinder, spring-fastenings for said collars, and conductors connecting said collars.

10. In an electric controller, means for electrically connecting two parallel contact-cylinders, comprising a divided collar on each cylinder, spring-fastenings for said collars, and one or more flexible conductors connecting said collars.

708,056. **VEHICLE.** NICHOLAS P. HANSEN, Sun Prairie, Wis. Filed Feb. 20, 1902. Serial No. 94,916. (No model.)



Claim.—1. In a vehicle-body, the combination with a side-board, a bottom, and a cross-brace under the bottom at the end of the body and projecting laterally beyond the side-board, of a corner angle-iron binder secured to said side-board and brace, one flange of which binder fits against the outer side of and is secured to the side-board and the other flange of which fits against the end of the body, the side flange being at its lower end turned outwardly transversely and fitted and secured to the top surface of the cross-brace, and the end flange being at its lower end at a distance below the end of the side flange turned inwardly transversely and fitted and secured to the lower surface of the cross-brace.

2. A binder for a vehicle-body, consisting of a section of angle-iron or similar material, the flanges of which are of unequal length the shorter flange at its lower end being turned transversely outwardly and the longer flange being turned transversely inwardly at a distance below the termination and transverse portion of the shorter flange, the binder having provision for securing it to the corner of a vehicle-body.

708,057. **DISPLAY-CABINET FOR PACKETS.** ALEXANDER W. M. MARSH, St. Paul, Minn., assignor to Lewis L. May, St. Paul, Minn. Filed Aug. 13, 1901. Serial No. 71,726. (No model.)

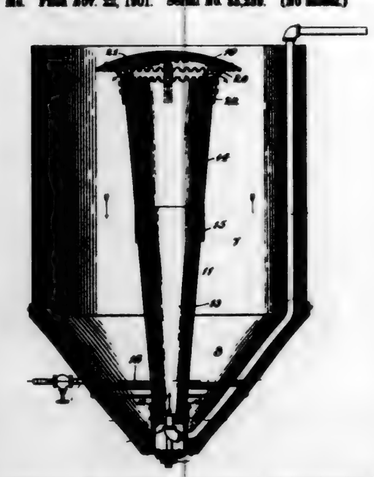
Claim.—1. In a display-case of the class described, the combination with an outer frame, of a frame rotatably supported therein, a series of horizontal receptacles pivotally supported in said inner frame, vertical strips arranged at the forward sides of said receptacles constituting intermediate openings, a strip secured to the upper ends of said vertical strips and formed with an inwardly and downwardly projecting lip, and partition-walls arranged transversely of said receptacles adjacent to said vertical strips.

2. In a case or use cases described, the combination of a frame, a series of receptacles arranged transversely thereof, inwardly-projecting flanges carried by the side walls of said frame, outwardly-projecting pivots carried by the ends of said receptacles and projecting through said flanges, and means carried by said receptacles for abutting against said flanges to limit the movement of said receptacles.

3. In a display-case of the class described, the combination with a frame, of a series of receptacles transversely arranged therein, inwardly-projecting flanges carried by the side walls of said frame, a pivotal connection between the lower ends of said receptacles and said flanges, and means carried by said receptacles for abutting against the flanges to limit the movement of said receptacles.

4. In a display-case of the class described, the combination with a frame, of a series of receptacles transversely arranged therein, inwardly-projecting flanges carried by the side walls of said frame, wires diagonally secured to the ends of said receptacles, the lower ends of said wires being bent outwardly and projecting through the adjacent flanges upon the side walls of the frame, and the upper ends of said wires being outwardly bent to abut against said flanges and limit the movement of said receptacles.

708,058. **AGITATOR.** HERMAN M. MARTINSEN, Rumford Falls, Me. Filed Nov. 22, 1901. Serial No. 83,239. (No model.)



Claim.—1. In an agitator, a reservoir, a mixing-chamber in said reservoir, provided with an inlet and an outlet opening, said chamber made in parts, and means to adjust said parts longitudinally with relation to each other to vary the distance between the inlet and outlet openings in said mixing-chamber.

2. In an agitator, a reservoir, a mixing-chamber in said reservoir, provided with an inlet and an outlet opening, said chamber made in parts, means to adjust said parts longitudinally with relation to each other and vary the distance between the inlet and outlet openings in said mixing-chamber, and an agitator-pipe leading from the interior of said mixing-chamber to a source of power.

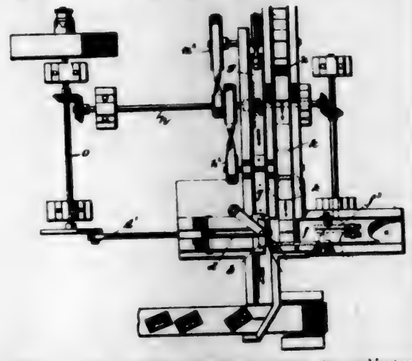
3. In an agitator, a reservoir, a mixing-chamber in said reservoir, provided with an inlet and an outlet opening, and an agitator-pipe leading from the interior of said mixing-chamber to a source of power, the outlet end of said mixing-chamber being notched for the purpose set forth.

4. In an agitator, a reservoir, a mixing-chamber in said reservoir, provided with an inlet and an outlet opening, an agitator-pipe leading from the interior and lower end of said mixing-chamber to a source of power, and a cap fast to said mixing-chamber and extending across said outlet-opening at a distance therefrom, whereby an annular space is provided between said cap and the outlet end of said mixing-chamber.

5. In an agitator, a reservoir, a mixing-chamber in said reservoir, provided with an inlet and an outlet opening, an agitator-pipe leading from said inlet-opening to a source of power, and a cap fast to said mixing-chamber and extending across said outlet-opening, the edge of said cap being notched for the purpose set forth.

6. In an agitator, a reservoir, a mixing-chamber in said reservoir, provided with an inlet and an outlet opening, said chamber being conical in shape, the large end of said mixing-chamber constituting the outlet-opening thereof and the small end of said mixing-chamber constituting the inlet-opening thereof, and an agitator-pipe leading from said inlet-opening to a source of power.

708,059. **FEEDING MECHANISM FOR PRESSES FOR PLASTIC MATERIAL.** JOHN R. MASSEAR and THOMAS BEVINGTON, Toronto Junction, Canada, assignors of one-half to David Brown, Donaghmore, Ireland. Filed Dec. 11, 1901. Serial No. 86,472. (No model.)



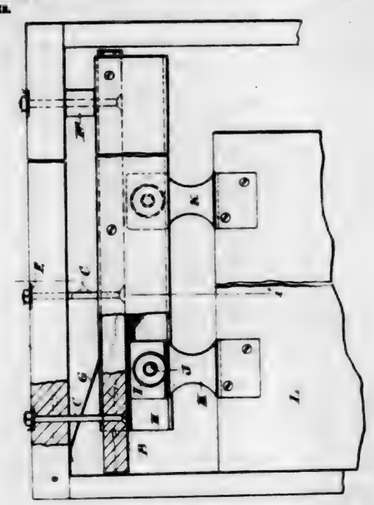
Claim.—1. In a pressing or stamping machine, the combination with the dies and means for operating them, of a charging-table and a charger for pushing the bars to be pressed from said table between the dies, a main conveyer for receiving the bars in a row, standing upright, side by side, an intermediate feeding device adapted to receive said bars from the main conveyer and to transfer them to the charging-table, means for moving the conveyer and means for turning each bar upon its side in the course of its travel, whereby each bar is delivered flat upon the charging-table, substantially as described.

2. In a machine of the character described, the combination with the vertically-reciprocating dies, of a charging-table or guideway leading to the dies, a charger and means for moving the same across said charging-table toward the dies, an inclined feeding-chute communicating at the bottom with the side of the charging-table and adapted to introduce bars placed in said chute laterally onto the charging-table into the path of the charger, and conveying mechanism adapted to receive unpressed bars in a row standing side by side, and arranged to deliver the bars one by one edge to edge into the upper portion of said feeding-chute.

3. In a machine of the character described, the combination with the vertically-reciprocating dies, of a charging-table or guideway leading to the dies, a reciprocating charging-plunger arranged to slide in said guideway, and means for operating said plunger, an inclined feeding-chute communicating at the bottom with the charging-table or guideway, a main conveyer adapted to receive a row of soap bars standing on edge side by side, a supplementary conveyer in alinement with the main conveyer and adapted to receive bars from the end of said main conveyer and to transfer said bars to the upper end of the feeding-chute, the two conveyers being arranged relatively to one another so that the soap bars will fall on their sides in passing from one to the other, and means for driving said conveyers, the supplementary conveyer being driven faster than the receiving-conveyer.

708,060. **DOOR-HANGER.** GUSTAV O. MEYER, Milwaukee, Wis. Filed Apr. 9, 1902. Serial No. 102,046. (No model.)

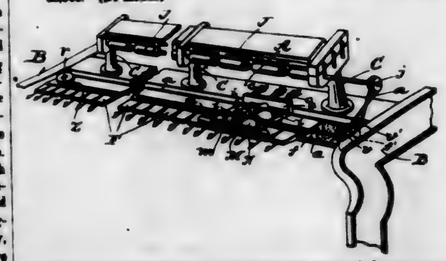
Claim.—1. The combination of a stationary suspension-bar, an adjusting-bar held in connection with the suspension-bar by screw bolts and nuts, a spring under tension between said bars adjacent to ends of same, angle-irons in connection with adjusting-bar having depending lower portions constituting parallel tracks, brackets attachable to a door, spindles carried by the brackets, and rollers on the spindles adapted to bear on the tracks.



2. The combination of a stationary suspension-bar, an adjusting-bar held in connection with the suspension-bar by screw bolts and nuts, a fulcrum-block intermediate of said bars adjacent to ends of same, angle-irons in connection with the adjusting-bar having depending horizontal portions constituting parallel tracks, brackets attachable to a door, spindles carried by the brackets, and rollers on the spindles adapted to bear on the tracks.

3. The combination of a stationary suspension-bar, an adjusting-bar held in connection with the suspension-bar by screw bolts and nuts, a fulcrum-block intermediate of the bars adjacent to ends of same, a spring under tension between said bars adjacent to the ends of same farthest from the fulcrum-block, angle-irons in connection with adjusting-bar having depending lower portions constituting parallel tracks, brackets attachable to a door, spindles carried by the brackets, and rollers on the spindles adapted to bear on the tracks.

708,061. **CLEANER FOR SPINNING-MACHINES.** SEVERUS MOOK, Pawtucket, and CHARLES D. ROBINSON, Crompton, R. I.; said Robinson assignor to said Mook. Filed Nov. 16, 1901. Serial No. 82,569. (No model.)



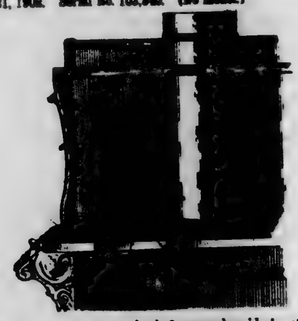
Claim.—1. In a cleaner for ring-spinning frames of the type mentioned the traveler N having upon its under surface a recess W, and the openings *c' c'* connecting therewith, substantially as described.

2. In a cleaner for ring-spinning frames, the traveler N; a guard fixed thereto and projecting downwardly and outwardly therefrom so that the lower front edge of the guard rests upon the guide-wires while the interior surface of said lower edge is in contact with or in close proximity to the front edge of the filler-blocks, in combination with said filler-blocks and guide-wires, substantially as described.

3. In a cleaner for ring-spinning frames of the type mentioned, a traveler N having a recessed under surface and at each end of said traveler an opening connecting with said recess; a fibrous material lining said recess; a guard fixed upon said traveler and carving downwardly and outwardly therefrom so that its lower edge rests upon the guide-wires while the inner surface of said lower edge is in contact with or in close prox-

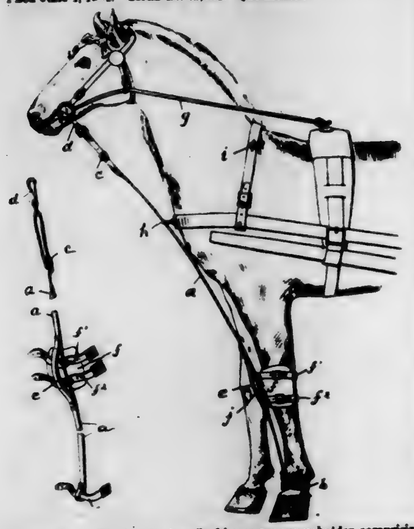
imity to the lifter-blocks; the whole in combination with said lifter-blocks and guide-wires, substantially as set forth.

708,062. COOKING-STOVE. WILLIAM H. MOORE, Joliet, Ill. Filed Apr. 21, 1902. Serial No. 103,840. (No model.)



Claim.—A stove having a back frame and a side bracket at its rear and also a key-plate in its top, adjacent to said bracket, said key-plate being pivotally connected at its inner edge to the stove-top, so that it will swing upwardly and inwardly, a lifting and suspending device connected to the rear outer corner of the key-plate, adjacent to said side bracket, and extending upward and connected to said side bracket, and means for locking said suspending device when the key-plate is lifted.

708,063. HORSE-HOPPLE. WILLIAM L. MORRISSEY, Summit, N. J. Filed June 1, 1901. Serial No. 62,751. (No model.)

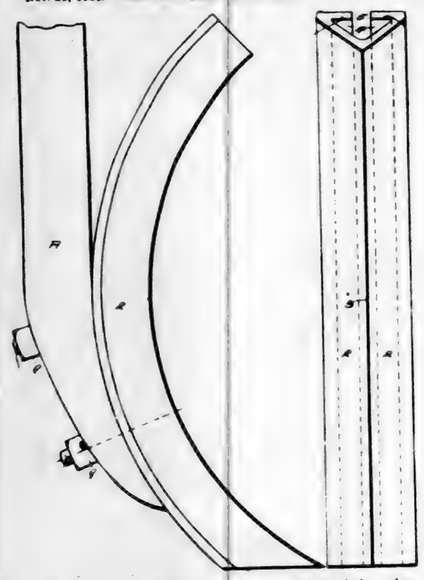


Claim.—1. The herein-described horse hopple or holder, comprising a strap adjustable in length and adapted at one end to be fastened to the horse's bit, means at the other end of said strap for fastening it to the ankle, between the fetlock and hoof, of one of the horse's fore feet, and a knee cap or cushion slidably secured to the strap intermediate of its ends and adapted to buckle firmly to the knee of the same leg to which the strap is fastened.

2. In a horse hopple or holder, a strap *a*, adapted at one end to be attached to the bit and at the other end to be buckled around the ankle, between the fetlock and hoof, of one of the horse's fore feet, and a knee cap or cushion adapted to be strapped firmly to the knee of the same leg to which the strap is buckled and having loops through which said strap passes.

3. The combination of the strap *a*, a band *b*, for the ankle of a horse's fore leg at one end of said strap, a snap-hook *d*, for the bit adjustably secured to the other end, a strip *e*, secured at its ends to said strap intermediate of said band and snap-hook and forming a loop *j*, a cap or cushion *f*, for the knee of the said fore leg, and fastening-bands *f'*, *f''*, for said cap or cushion passing loosely through the loop *j*, whereby the strap may slide with respect to said cap or cushion when the latter is fixed by its bands.

708,064. CULTIVATOR. JOHN A. MCKINNON, Hiuajos, Cal. Filed Nov. 29, 1901. Serial No. 84,102. (No model.)



Claim.—1. A cultivator-tooth having a longitudinal channel to receive the head of a bolt and a slot in the rear side of the tooth intermediate the sides of the channel and communicating therewith, substantially as described.

2. In combination with a cultivator-tooth having a longitudinal channel, a longitudinal slot in its rear side communicating with said channel and flanges forming the sides of said slot and the rear side of said channel, a cultivator-standard and a bolt connecting said tooth to said standard, the head of said bolt being disposed in said channel and the shank thereof disposed in said slot, whereby the said cultivator-tooth is adjustably secured to said standard, substantially as described.

708,065. BOOKBINDING. JOHN L. MCMILLAN, Ilion, N. Y. Filed July 9, 1900. Serial No. 695,518. (No model.)

Claim.—1. The herein-described binding for loose sheets, comprising a back 3; boards 1 and 2 hinged to said back; binding-strips 7, attached at one end to the cover and having open barrels or hooks at the other end; a notched barrel or tube 5 made fast to the cover; a rod adapted to pass through the barrel 5 and the open barrels or hooks of the binding-strips; a series of attaching-strips 14 provided with perforate ears to receive the binding-strips; and sheets slitted to receive the ears and applied thereto, substantially as described.

2. In combination with a cover provided with plates 4, having barrels 5 provided with openings 6, binding-strips 7 provided with barrels 8 and hooks or open barrels 11; and rods 9 and 18 for securing the binding-strips to the plates 4.

3. In combination with a cover provided with barrels 5 having openings or notches 6; binding-strips 7 provided with barrels 8 and hooks or open barrels 11; attaching-strips 14 provided with ears having perforations 17; and rods 9 and 18 for attaching the binding-strips to the barrels 5.

4. In combination with a cover or binder; a hinged binding-strip to carry or sustain the sheets; a barrel secured to the cover and having an opening to receive the free end of the binding-strip; a rod passing through the barrel and serving to attach the binding-strip thereto; and rigid spurs permanently projecting into the barrel and serving to prevent withdrawal of the rod.

5. In combination with a book-cover, a plate secured thereto and provided with a barrel 5 having an opening 6; a binding-strip 7 provided with a barrel 8 seated in the opening 6; a rod passing through the barrels 5 and 8; and rigid spurs 10 cast from the metal of barrel 5, projecting into the same, and serving to prevent withdrawal of the rod, substantially as and for the purpose set forth.

6. In combination with a cover; binding-strips attached thereto; attaching-strips having perforated ears some of which are strung upon the binding-strips; and elastic bands attached to the cover and having one end free to be passed through ears of the attaching-strips, substantially as and for the purpose explained.

7. In combination with a suitable cover, a series of perforated attaching-strips adapted to carry leaves or sheets to be bound; and an elastic band attached to the cover, larger in cross-section than the perforations, whereby it is adapted to be drawn through the perforations of the attaching-strips when elongated and to expand laterally when released; causing it to bind in the perforations and by contracting longitudinally, draw the attaching-strips firmly together.

8. In a binder, the combination of a suitable cover; binding-strips within said cover; single or unfolded sheets or leaves having perforations through them from face to face near the binding edge; and attaching-strips having perforate ears passing through the sheets or leaves and strung upon the binding-strips, substantially as described.

9. In a binder, the combination of a series of single or unfolded sheets or leaves, and a series of attaching-strips, one for each sheet or leaf, each strip having a tongue passing through one leaf from face to face at a point a short distance inward from the binding edge.

10. In combination with a suitable cover provided with a notched barrel; a binding-strip having a barrel to enter the notch of the main barrel; and a hinge-rod for connecting the two barrels provided with a head or projecting portion to reach outside the barrel, and with a notch below said head to facilitate the removal thereof.

11. In combination with a suitable cover, a series of attaching-strips 14 provided with perforate ears; and an elastic band arranged to pass through the perforate ears, said band being normally of larger measurement in cross-section, in a given direction, than the perforation through which it passes.

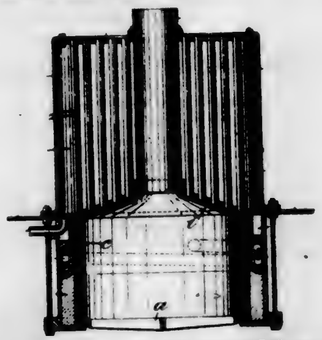
12. In combination with a suitable cover, a series of attaching-strips provided with perforate ears; and an elastic band of larger cross-section than the perforations of the ears, but provided with a tab of smaller section.

13. A book, a series of cross-pieces therein having open hook ends, means within the book located to be engaged by the hooks, and means for detachably securing pages to said cross-pieces.

14. A book, comprising a cover having a hinge member, a series of cross-pieces having hinge members at their ends, a rod adapted to pass through the hinge members and having a weakened place, and means for detachably securing a series of pages to the cross-pieces.

15. In combination with a cover provided with barrels having openings, binding-strips provided with hooks or open barrels, and rods for securing the binding-strips to the covers.

708,066. STEAM-GENERATOR. WILLIAM HORRIE, Blackpool, and HENRY SPURRIER, St. Annes-on-the-Sea, England. Filed Feb. 26, 1902. Serial No. 96,562. (No model.)



Claim.—1. In steam-generators of the class described, a crown-plate having parts extending beyond the extreme diameter of the fire-box and forming a means of support for the boiler, in combination with means for suspending the fire-box therefrom, substantially as set forth.

2. In steam-generators of the class described, a cast-iron ring surrounding the upper part of the fire-space and having recesses formed in the outer part of its upper edge for the reception of mud-cock elbows, substantially as set forth.

3. In steam-generators of the class described, the combination with a fire-box crown-plate, of angular extensions integral with the plate, a cast-iron ring suspended from the crown-plate, recesses cast in the upper outer part of the ring, and mud-cock elbows contained within the said recesses, substantially as set forth.

708,067. WINDOW-FASTENER. LEONARD D. PARIS, Gatesville, Tex., assignor of one-half to John T. Post, Gatesville, Tex. Filed May 15, 1902. Serial No. 107,488. (No model.)

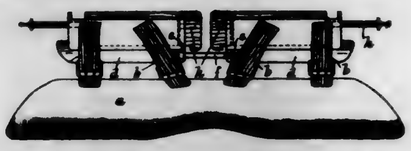
Claim.—1. A combined window fastener and lock, comprising a casing, a pair of cams pivotally mounted therein and provided with eccentric and coöperating meeting surfaces, an operating-handle, and a pin or stud on one cam, and a spring having its free end bearing against said pin or stud and adapted thereby to hold the cams either in their operative or inoperative positions, substantially as described.

2. A combined window-sash fastener and lock, comprising a casing, a pair of cams fulcrumed therein and provided with eccentric and coöperating meeting surfaces, and operating-handle, and a pin or stud on one cam, a spring bearing against said pin or stud and adapted to hold the cam either in its operative or inoperative position, and a stop-shoulder on the casing, one of the cams being cut away to form a coöperating stop-shoulder and to give the cam a preponderance of weight upon one side of its fulcrum.

708,068. SURGICAL APPLIANCE. PHILIP H. T. PARLIERTI, Philadelphia, Pa. Filed May 6, 1902. Serial No. 106,313. (No model.)

Claim.—1. A surgical appliance for fractured patellæ consisting of a splint adapted to keep the knee-joint rigid, two saddle-pieces arranged to

fit above and below the knee, adjustable means for connecting the said saddle-pieces together, blocks slidingly engaged in said saddle-pieces and means provided on each saddle-piece for forcing the blocks toward each other, substantially as described.



2. In a surgical appliance for fractured patellæ a device for putting pressure upon the patella above and below the knee in combination with an attachment having adjustable sliding blocks adapted to put lateral pressure upon the patella, substantially as described.

708,069. PROCESS OF STAINING WOODS. JOSEF PFEIFER, Vienna, Austria-Hungary, assignor to Joachim von Brunner, Schloss Goldford, Austria-Hungary. Filed Feb. 12, 1902. Serial No. 93,905. (No specimens.)

Claim.—1. The process of staining woods under liquid-pressure, which consists in applying successively to one face of the article or wood to be treated the desired patterns and then forcing in succession the dyeing liquid within a closed receptacle under pressure through each pattern to show the decided colored patterns therethrough, when finished, substantially as set forth.

2. The process of staining woods under liquid-pressure, which consists in applying to one face of the wood to be treated a pattern, forcing the dyeing liquor under pressure through the wood to penetrate the texture of the wood in axial direction and continuing the pressure of the forcing liquid through the wood to cause its penetration through the pores of the wood in a lateral direction, substantially as and for the purposes set forth.

708,070. COHERER. GREENLEAF W. PICKARD, Boston, Mass., assignor, by mesne assignments, to Consolidated Wireless Telegraph and Telephone Company, a Corporation of Arizona Territory. Filed Oct. 18, 1901. Serial No. 79,107. (No model.)

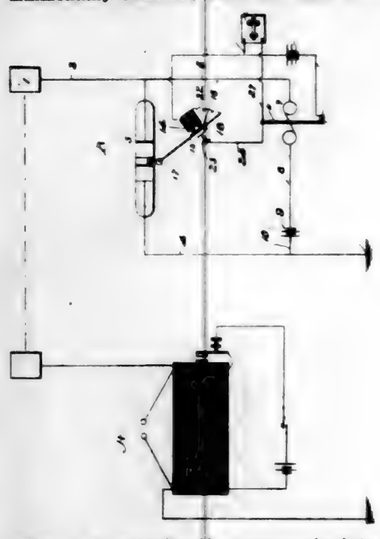
Claim.—1. A coherer, comprising a non-conducting tube, conducting-wires entering said tube from opposite ends, metallic plugs surrounded by said tube and connected to the wires, said plugs having their adjacent ends provided with a concavity so as to form a pocket whose greatest width is between the center of the adjacent ends of the plugs and whose narrowest width is between the extreme edges of the adjacent faces of the plugs and metallic filings or particles located in said pocket below the axial line of said plugs.

2. A coherer, comprising a non-conducting tube, conducting-wires entering said tube from opposite ends, metallic plugs surrounded by said tube and connected to the wires, the inner faces of said plugs being concaved so as to form a substantially elliptical or circular pocket in cross section, and metallic particles located in the pocket so formed.

3. A coherer, comprising a non-conducting tube, metallic plugs in said tube and providing a pocket between their adjacent faces, said pocket having its greatest breadth between the axial line of the plugs, and its narrowest breadth between the extreme edges of the adjacent faces of the plugs, metallic filings or particles between said plugs below the axial line thereof, and conductor-wires connected to the outer faces of said plugs.

4. A metallic plug for a coherer, comprising a substantially cylindrical body having a concaved surface upon one end and a surface upon the other end to engage a wire, said concaved surface having its deepest concavity in its axial line and radiating in all directions to form an overhanging periphery.

708,071. WIRELESS-TELEGRAPH SYSTEM. GREENLEAF W. PICKARD, Boston, Mass., assignor, by mesne assignments, to Consolidated Wireless Telegraph and Telephone Company, a Corporation of Arizona Territory. Filed Oct. 29, 1901. Serial No. 80,382. (No model.)



Claim.—1. In combination with a wave-responsive device, a decohering means therefor, said decohering means having automatic means for regulating the operation thereof according to the resistance of the said wave-responsive device.

2. In combination with a wave-responsive device, a decohering means therefor, comprising an electromagnetically-operated means, and a circuit to regulate the operation of said electromagnetically-operated means according to the resistance of the wave-responsive device.

3. In a receiver for electrical oscillations, the combination of a receiving means, a circuit therethrough, a relay in said circuit, a decohering-circuit operated by said relay, a recorder-circuit in shunt to said decohering-circuit, and an imperfect electrical contact regulated by the relay according to the resistance of the receiving means to energize the decohering-circuit accordingly.

4. In a receiver for electrical oscillations, the combination of a receiving means, a circuit therefor, a relay in said circuit, a decohering-circuit operated by said relay, a recorder-circuit in shunt to said decohering-circuit, a lever or armature operated by the relay to energize the recorder and decohering-circuit, an imperfect electrical contact made by said armature regulated by the resistance of the receiving means, and a decohering means in said decohering-circuit.

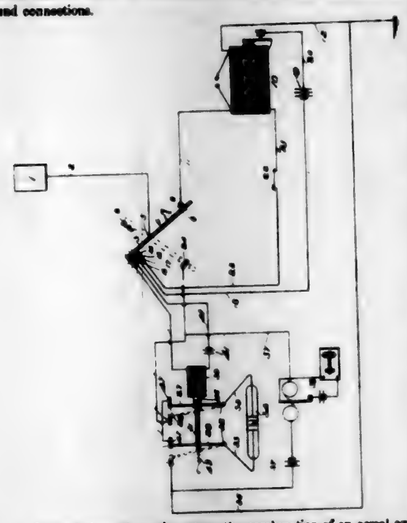
5. In a receiver, the combination of receiving means, a circuit therefor, a relay in said circuit, a decohering-circuit operated by said relay, a recorder-circuit in shunt to said decohering-circuit, an imperfect electrical contact regulated by the relay according to the resistance of the receiving means to energize the decohering-circuit, and a decohering means in said decohering-circuit.

6. In a receiver, the combination of receiving means, a circuit therefor, a relay in said circuit, a decohering-circuit controlled by said relay, a decohering means in said decohering-circuit, and means operated by the relay to regulate the decohering means according to the resistance of the receiving means.

708,072. WIRELESS TELEGRAPHY. GREENLEAF W. PICKARD, Boston, Mass., assignor, by mesne assignments, to Consolidated Wireless Telegraph and Telephone Company, a Corporation of Arizona Territory. Filed Nov. 4, 1901. Serial No. 81,079. (No model.)

Claim.—1. In a wireless-telegraph system, the combination of a single aerial and ground connection, a transmitter and receiver, manually-operated means for connecting the transmitter or receiver with the connections, and means operated by said first-mentioned means for disconnecting the coherer from the receiver.

2. In a wireless-telegraph system, the combination of aerial and ground connections, a transmitter and a receiver, manually-operated means for connecting the aerial connection with the transmitter or receiver, and means operated by said above-mentioned means for cutting the coherer from the receiver when the transmitter is connected with the aerial and ground connections.



3. In a wireless-telegraph system, the combination of an aerial and ground connection, a transmitter, a receiver, an imperfect electrical contact in the receiver, manually-operated means for connecting the transmitter or receiver with the aerial and ground connections and means operated by said last-mentioned means for cutting the imperfect electrical contact from the receiver when the transmitter is connected with the aerial and ground connections.

4. In a wireless-telegraph system, the combination of an aerial and ground connection, a transmitter and a receiver, an imperfect electrical contact in said receiver, manually-operated means for connecting the transmitter or receiver with the aerial and ground connections, and means operated by said means for cutting the imperfect electrical contact from the receiver when the transmitter is connected with the aerial and ground connections.

5. In a wireless-telegraph system, the combination of an aerial and a ground connection, a transmitter, a receiver, a wave-responsive device in said receiver, means for disconnecting said wave-responsive device from the receiver, a switch for connecting the transmitter or receiver to the aerial and ground connections and means operated by said wave-responsive-device-disconnecting means when said switch connects the transmitter with the aerial and ground connections.

6. In a terminal station, the combination of an aerial and ground connection, a transmitter, a receiver having a wave-responsive device therein, a switch for connecting the transmitter or receiver with the aerial and ground connection, and means operated by said switch to prevent the wave-responsive device from being damaged by radiations from the transmitter when the transmitter is connected with the aerial and ground connections.

7. In a terminal station, the combination of an aerial and ground connection, a transmitter, a receiver consisting of an imperfect electrical contact, a pair of arms connected in circuit with said contact, a circuit through said arms and contact, an electromagnet, means for operating the arms to cut the contact from its circuit, means for returning the arms, and a switch for connecting the transmitter or receiver with the aerial and ground connections, said electromagnetically-operated means being operated when the transmitter is connected with the aerial and ground connections.

8. In a wireless-telegraph system, the combination of a single aerial and ground connection, a transmitter and receiver, means for connecting the transmitter or receiver with the connections, comprising a pivoted lever of insulation material having contacts on each end for making the connections, and means operated by said first-mentioned means for disconnecting the coherer from the receiver.

9. In a wireless-telegraph system, the combination of aerial and ground connections, a transmitter and a receiver, manually-operated means for connecting the aerial connection with the transmitter or receiver, comprising a pivoted lever of insulation material having contacts on each end for making the connections, and means operated by said above-mentioned means for cutting the coherer from the receiver when the transmitter is connected with the aerial and ground connections.

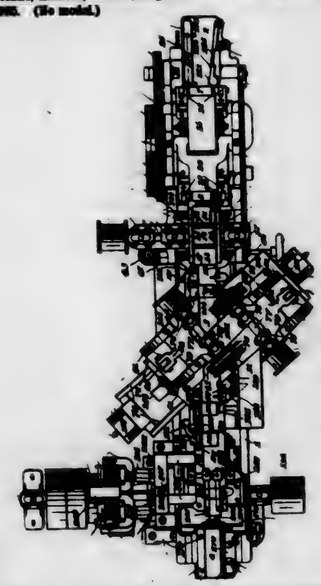
10. In a wireless-telegraph system, the combination of an aerial and ground connection, a transmitter, a receiver, an imperfect electrical contact in the receiver, means for connecting the transmitter or receiver with the aerial and ground connections, comprising a pivoted lever of insulation material having contacts on each end for making the connections, and means operated by said last-mentioned means for cutting the imperfect electrical contact from the receiver when the transmitter is connected with the aerial and ground connections.

11. In a wireless-telegraph system, the combination of an aerial and a ground connection, a transmitter, a receiver, a wave-responsive device in said receiver, means for disconnecting said wave-responsive device from the receiver, a switch for connecting the transmitter or receiver to the aerial and ground connections, comprising a pivoted lever of insulation material having contacts on each end for making the connections, and means operated by said wave-responsive-device-disconnecting means when said switch connects the transmitter with the aerial and ground connections.

12. In a terminal station, the combination of an aerial and ground connection, a transmitter, a receiver, a switch for connecting the transmitter or receiver with the aerial and ground connections, comprising a pivoted lever of insulation material having contacts on each end for making the connections, and means operated by said switch to prevent the receiver from being damaged, when the transmitter is connected with aerial and ground connections.

13. In a terminal station, the combination of an aerial and ground connection, a transmitter, a receiver, consisting of an imperfect electrical contact, a pair of arms connected in circuit with said contact, a circuit through said arms and contact, an electromagnet, means for operating the arms to cut the contact from its circuit, means for returning the arms, and a switch for connecting the transmitter or receiver with the aerial and ground connections, comprising a pivoted lever of insulation material having contacts on each end for making the connections, said electromagnetically-operated means being operated when the transmitter is connected with the aerial and ground connections.

708,073. FIRE-LIGHTER MACHINE. EDWIN POLLARD, Bilston, England, and JOHN B. THOMAS, Cincinnati, Ohio, assignors to Pollard & Metcalfe, Limited, Bilston, England. Filed July 27, 1901. Serial No. 69,925. (No model.)



Claim.—1. In combination, cutters for making longitudinal grooves on one side of the material, cutters for making grooves transversely on the other side of the material, said cutters being arranged to cut into the same intermediate plane and through the material at the intersection of the grooves and intermittent feeding mechanism, substantially as described.

2. In combination, cutters for making longitudinal grooves on one side of the material, cutters for making grooves transversely on the other side of the material, means for moving said transverse grooving-cutters

to and from the path of the material so that said lengthwise and transverse cutters cut into the same intermediate plane and through the material at the intersection of the grooves and intermittent feeding means, substantially as described.

3. In a fire-lighter machine, the combination of a transversely-reciprocating carriage, a grooving device mounted thereon and reciprocating therewith, a table for the stock between the grooving device and the carriage, and a holddown-plate taking above the stock secured to and reciprocating with the carriage, substantially as described.

4. In a fire-lighter machine, the combination of a transversely-reciprocating carriage, a grooving device mounted thereon and reciprocating therewith, a table for the stock between the grooving device and the carriage, and a holddown-plate taking above the stock secured to and reciprocating with the carriage, with springs for yieldingly holding the plate against the stock, substantially as described.

5. In a fire-lighter machine, the combination of a frame, a carriage reciprocating diagonally with relation thereto, grooving-cutters mounted thereon and moving diagonally therewith, a table stationarily positioned between the cutters and the carriage, and a diagonally-reciprocating pressure-plate for the stock reciprocating with the carriage.

6. In a fire-lighter machine, the combination of a frame, a carriage reciprocating transversely thereof, a pair of grooving devices mounted thereon, a holddown-plate between the grooving devices, with an intermittent feed, constructed and arranged for having the pressure-plate take over a cut end an uncut portion of a strip of stock at each forward movement of the feed.

7. In a fire-lighter machine, the combination of a frame, a transversely-reciprocating carriage, a pair of grooving devices mounted thereon and reciprocating therewith, a stationary table for the stock between the grooving devices and the carriage, with a holddown-plate for the stock above the table and between the pair of transversely-reciprocating grooving devices.

8. In a fire-lighter machine, the combination of a frame, a transversely-reciprocating carriage, grooving-cutters mounted thereon, a feeding device, a cutting-off saw, an arbor therefor, a reciprocating frame in which the arbor is mounted, a reciprocating feeding-out table, a rock-shaft, with connections for the saw-arbor and the feeding-out table to the reciprocating frame of the saw-arbor through the rock-shaft for longitudinally reciprocating the saw-arbor and feeding-out table.

9. In a fire-lighter machine the combination of a frame, a transversely-reciprocating carriage, grooving-cutters mounted thereon, a feeding device, a cutting-off saw, an arbor therefor, a reciprocating frame in which the arbor is longitudinally slidable, a feeding-out table, a rock-shaft, rocking arms and links connecting the saw-arbor and feeding-out table with the rock-shaft, and a connection between the reciprocating frame of the saw-arbor and the rock-shaft for rocking the latter.

10. In a fire-lighter machine, the combination of a frame, a transversely-reciprocating carriage, grooving-cutters mounted thereon, a feeding device, a cutting-off saw, an arbor therefor, a reciprocating frame in which the arbor is longitudinally slidable, a feeding-out table, a rock-shaft, rocking arms and links connecting with the saw-arbor and feeding-out table, a plurality of connections between the rocking arms and links for varying the longitudinal movement of the saw-arbor and feeding-out table, and a connection between the reciprocating frame of the saw-arbor and the rock-shaft for rocking the latter.

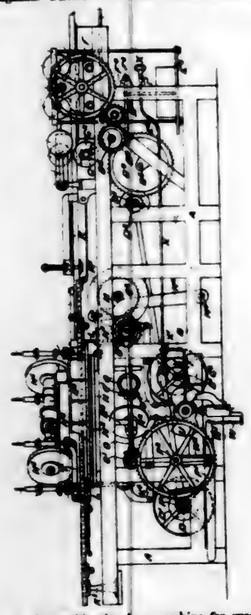
11. In a fire-lighter machine, the combination of a frame, a transversely-reciprocating carriage mounted thereon, with grooving means for the carriage, feeding mechanism, an intermittently-operating shaft for the feeding mechanism, a cutting-off saw, a shaft extending longitudinally of the machine, with gearing between the latter shaft and the intermittently-operating shaft of the feeding mechanism, a reciprocating frame for the cutting-off saw, with a crank and pitman between the latter and the longitudinal shaft for reciprocating the cutting-off saw.

12. In a fire-lighter machine, the combination of a feeding-out table, a saw-arbor, a reciprocating frame therefor, a crank for moving the frame, a rock-shaft, and connections between the saw-arbor and feeding-out table and the rock-shaft for longitudinally reciprocating the saw-arbor and feeding-out table simultaneously with the reciprocating movement of the saw-arbor frame imparted by the crank.

13. In a fire-lighter machine, the combination of a frame, a carriage reciprocating transversely thereof, grooving-cutters mounted thereon and moving therewith, a cutting-off saw, a reciprocating slidable arbor for the same, a frame for the latter, a slidable feeding-out table, a rock-shaft, with a plurality of connections respectively between the arbor and feeding-out table and the rock-shaft, with a reciprocating connection from the saw-arbor frame to the latter for simultaneously longitudinally sliding the saw-arbor and feeding-out table with the reciprocating movement of the arbor

14. In a fire-lighter machine, the combination of a frame, a transversely-reciprocating carriage, a grooving device mounted thereon and moving therewith, a cutting-off saw, a reciprocating frame for the same, an arbor for the saw slidable longitudinally in the frame, a feeding-out table, a rock-shaft, arms and links connecting the saw-arbor and feeding-out table with the rock-shaft, a plurality of connections between the arms and the links, a connection between the reciprocating frame of the saw-arbor and the rock-shaft for rocking the latter, with a crank for reciprocating the arbor-frame, a driving-shaft for the crank, with change-gears between the driving-shaft and crank-shaft, constructed and arranged for regulating the speed of reciprocations of the saw-arbor frame and longitudinal movement of the saw-arbor and feeding-out table.

708,074. MACHINE FOR GROOVING LUMBER. EDWIN POLLARD, Hinton, England. Filed Feb. 25, 1902. Serial No. 96,577. (No model.)



Claim.—1. In combination in a machine for grooving lumber, cutters for making longitudinal grooves on one side of the material, cutters for making grooves transversely on the other side of the material, said cutters being arranged to cut into the same intermediate plane and through the material at the intersection of the grooves, and feeding means substantially as described.

2. In a machine for grooving lumber, cutters for making longitudinal grooves on one side of the material, cutters for making grooves transversely on the other side of the material, said cutters being arranged to cut into the same intermediate plane and through the material at the intersection of the grooves, means for feeding and continuously propelling the lumber, and means for firmly holding or securing the traveling lumber during the longitudinal and transverse cuttings.

708,075. MOLD FOR MAKING PAPER-BOARD BURIAL CASKETS. ELMER A. POST, Allegan, Mich. Filed Oct. 24, 1900. Serial No. 34,177. (No model.)

Claim.—1. A mold for making paper-board burial-caskets and the like, consisting of a base-board, sides hinged thereto and adapted to be connected together at their ends, the posts rising from the base within the mold and threaded at their upper ends, a core or plunger fitting down over said posts and within the mold, and clamp-nuts on the upper ends of the posts, substantially as set forth.

2. A mold for forming laminated paper-board vessels, such as burial-caskets, a base provided with a pair of vertical posts, one rising from either end, a plunger or core fitting down over these posts and having its exterior shaped to conform to the interior of the casket, means for clamping the core or plunger down upon the base, hinged sides connected to the base and conforming to the exterior of the casket.

3. A mold for forming paper-board vessels, such as burial-caskets, comprised of a base, a pair of hinged sides, each of which is provided with a hinged section at each end, means for clamping the end sections together, and a removable core.

708,076. DEVICE FOR STOPPING OR CLOSING GAS-MAINS. ARTHUR POSTLEY, New York, N. Y. Filed Apr. 2, 1902. Serial No. 101,044. (No model.)

Claim.—1. A stopper or closure device for gas-mains comprising a contractible and expansible frame composed of main bars or links pivotally connected centrally thereof, supplemental bars or links pivotally connected with the ends of the main bars or links, and with each other, an elastic tube passing around and connected with the frame thus formed, a flexible covering secured to said frame, and handle-levers pivotally connected with the main bars or links of said frame and with each other, substantially as shown and described.

2. A stopper or closure device for gas-mains comprising a contractible and expansible frame composed of main bars or links pivotally connected centrally thereof, supplemental bars or links pivotally connected with the ends of the main bars or links and with each other, an elastic tube passing around and connected with the frame thus formed, a flexible covering secured to said frame, and hand-levers pivotally connected with the main bars or links of said frame and with each other, one of said handle-levers being provided with a pivoted pawl and the other with ratchet-teeth, substantially as shown and described.

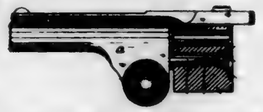
3. In a device of the class described an expansible and contractible frame composed of pivotally-connected main bars or links, supplemental bars or links pivotally connected with the ends of the main bars or links and with each other, an elastic tube inclosing said frame and secured thereto, a flexible covering inclosing one side of said frame and handle-levers connected with each other and with the main bars or links, substantially as shown and described.

708,077. LAST. DAVID L. PURINTON, Boston, Mass. Filed June 28, 1901. Serial No. 66,343. (No model.)

Claim.—The combination with the hinged last sections, of the bar, and the pivotal member for said bar comprising the U-shaped spring-strip one end of which is formed with the split eye pivotally holding an end of said bar, and the other end constructed to be fastened to the toe-section, substantially as described.

708,078. REVOLVER. JAMES D. ROSENBERG, Norwich, Conn., assignor, by mesne assignments, to The Thames Arms Company, Norwich, Conn., a Corporation. Filed Nov. 4, 1901. Serial No. 80,974. (No model.)

Claim.—1. In combination, a cylinder having a central axial opening with annular enlargement, as set forth, a barrel, and an axial stem fixed in said barrel; the free end portion of said stem being slotted and provided with an annulus adapted to engage the said annular enlargement in the cylinder.



2. The combination with a cylinder having an axial opening with annular enlargement between its ends, of a barrel having a fixed axial stem of less length than said opening and provided with slotted outer end with an annulus at the end of the slots to spring into said enlargement of the bore of the cylinder to prevent displacement of the latter without retarding its rotation, substantially as described.

708,079. PROCESS OF MAKING SODIUM CYANID. FRITZ ROESSLER, Frankfort-on-the-Main, Germany, assignor to the Roessler & Hasslacher Chemical Company, New York, N. Y., a Firm. Filed Feb. 4, 1899. Serial No. 704,584. (No specimens.)

Claim.—1. The method substantially as hereinbefore described of obtaining sodium cyanid, which consists in treating a mixture of sodium cyanid and sodium carbonate with insufficient water to dissolve the cyanid completely, forming a lye, separating the lye from the mixture, again treating the remaining mixture with such a quantity of water as is necessary to dissolve all the cyanid left in the mass after the first treatment forming a second lye, and lixiviating a fresh quantity of the mixture of sodium cyanid and sodium carbonate with the second lye, whereby the sodium carbonate in the solution is displaced by sodium cyanid, as and for the purposes set forth.

2. The method substantially as hereinbefore described of obtaining sodium cyanid, which consists in treating a mixture of sodium cyanid and sodium carbonate with insufficient water to dissolve the cyanid completely, forming a lye, separating the lye from the mixture, again treating the remaining mixture with such a quantity of water as is necessary to dissolve all the cyanid left in the mass after the first treatment, forming a second lye, lixiviating a fresh quantity of the mixture of sodium cyanid and sodium carbonate with the second lye, whereby the sodium carbonate in the solution is displaced by sodium cyanid, and depositing crystals of sodium cyanid by cooling, as and for the purposes set forth.

3. The method substantially as hereinbefore described of obtaining sodium cyanid, which consists in treating a mixture of sodium cyanid and sodium carbonate with insufficient water to dissolve the cyanid completely, forming a lye, separating the lye from the mixture, again treating the remaining mixture with such a quantity of water as is necessary to dissolve all the cyanid left in the mass after the first treatment, forming a second lye, lixiviating a fresh quantity of the mixture of sodium cyanid and sodium carbonate with the second lye, whereby the sodium carbonate in the solution is displaced by sodium cyanid, depositing crystals of sodium cyanid by cooling, and freeing the crystals from their water of crystallization, as and for the purpose set forth.

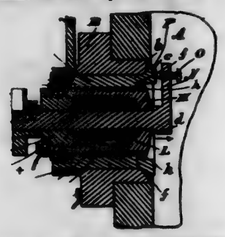
4. The method substantially as hereinbefore described of obtaining sodium cyanid, which consists in treating a mixture of sodium cyanid and sodium carbonate with insufficient water to dissolve the cyanid completely, forming a lye, separating the lye from the mixture, again treating the remaining mixture with such a quantity of water as is necessary to dissolve all the cyanid left in the mass after the first treatment, forming a second lye, lixiviating a fresh quantity of the mixture of sodium cyanid and sodium carbonate with the second lye, whereby the sodium carbonate in the solution is displaced by sodium cyanid, depositing crystals of sodium cyanid by cooling, and freeing the crystals of sodium cyanid in their water of crystallization at about 33° centigrade, whereby the cyanid is separated in a state free from water, as and for the purpose set forth.

708,080. REVOLVING ELECTRIC IGNITER. ARSON G. ROSAN, Toronto, Canada. Filed June 5, 1901. Serial No. 63,302. (No model.)

Claim.—1. In a revolving electric igniter, the combination with an electrode centrally mounted within an adjustable electrode from which it is insulated, and designed to turn therein, of said adjustable electrode, the same adjustable about its axis with reference to the other electrode.

2. In a revolving electric igniter, the combination with an electrode mounted centrally within an adjustable electrode from which it is insulated, and designed to turn therein, the said revolving electrode having a limited longitudinal movement, and means for limiting longitudinal movement of same, of said adjustable electrode, the same adjustable about its axis with reference to the other electrode, and means for adjusting said

adjustable electrode, the first-mentioned electrode being revolved and making a wipe contact with said adjustable electrode.



3. In a revolving electric igniter, the combination with an electrode centrally mounted within an adjustable electrode from which it is insulated, and designed to turn therein, the said revolving electrode having a limited longitudinal movement, an adjustable contact-point carried by the inner end of said revolving electrode, and stops on said revolving electrode for limiting longitudinal movement of same, of said adjustable electrode, the same adjustable about its axis with reference to the other electrode, and means for adjusting said adjustable electrode, the first-mentioned electrode being revolved and making a wipe contact with said adjustable electrode.

4. In a revolving electric igniter, the combination with an electrode centrally mounted within an adjustable electrode from which it is insulated, and designed to turn therein, the said revolving electrode having a limited longitudinal movement, an adjustable contact-point carried by the inner end of said revolving electrode, and stops on said revolving electrode for limiting longitudinal movement of same, of said adjustable electrode, a contact-point on the inner end of same and projecting outwardly from same, the said adjustable electrode adjustable about its axis with reference to the other electrode, and means for adjusting said adjustable electrode, the first-mentioned electrode being revolved so that its contact-point will make a wipe contact with said contact-point of said adjustable electrode.

5. In a revolving electric igniter, the combination with an electrode centrally mounted within an adjustable electrode from which it is insulated, and designed to turn therein, the said revolving electrode having a limited longitudinal movement, an adjustable contact-point carried by the inner end of said revolving electrode, and stops on said revolving electrode for limiting longitudinal movement of same, of said adjustable electrode, a contact-point on the inner end of same and projecting outwardly from same, the said adjustable electrode adjustable about its axis with reference to the other electrode, and a lever on the outer end of said adjustable electrode for adjusting same, the first-mentioned electrode being revolved so that its contact-point will make a wipe contact with said contact-point of said adjustable electrode.

6. In a revolving electric igniter, the combination with an electrode mounted centrally to revolve within an adjustable electrode from which it is insulated, and a contact-point carried by the inner end of said revolving electrode, of said adjustable electrode, the same essentially quickly adjustable with reference to the revolving electrode, and means for adjusting said adjustable electrode.

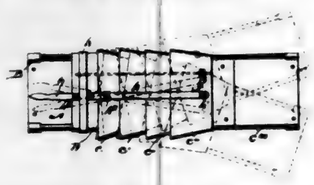
7. In a revolving electric igniter, the combination with an electrode mounted centrally to revolve within an adjustable electrode from which it is insulated, and an adjustable contact-point carried by the inner end of said revolving electrode, of said adjustable electrode, and a contact-point on the inner end of same and projecting outwardly therefrom, the said adjustable electrode essentially quickly adjustable with reference to the revolving electrode, and means for adjusting said adjustable electrode.

8. In a revolving electric igniter, the combination with an electrode mounted centrally to revolve within an adjustable electrode from which it is insulated, and an adjustable contact-point carried by the inner end of said revolving electrode, of said adjustable electrode, and a contact-point on the inner end of same and projecting outwardly therefrom, the said adjustable electrode essentially quickly adjustable with reference to the revolving electrode, and an arm on the outer end of said adjustable electrode for adjusting same.

708,081. CHUTE. FRANK L. SACKETT, Fredonia, N. Y. Filed Mar. 17, 1902. Serial No. 98,477. (No model.)

Claim.—1. A flexible chute comprising a main body portion and a series of adjustable portions, and means for connecting said portions comprising spaced pivots arranged substantially one above the other in a vertical plane whereby said chute is vertically rigid and laterally flexible, and means for positively locking said sections in various laterally-adjusted positions for the purpose described.

2. A flexible chute comprising, rigid open-top end portions, a series of intermediate portions connected to each other and to said end portions, and means for connecting said portions comprising spaced pivots arranged substantially one above the other in a vertical plane whereby said chute is vertically rigid and laterally flexible, for the purpose described.



3. A flexible chute comprising open-top end portions and an intermediate cover portion flexibly connected to said end portions, for the purpose described.

4. A flexible chute comprising open-top end portions, and intermediate tubular tapered portions pivotally connected to each other and secured to said end portions, for the purpose described.

5. A flexible chute comprising an open-top portion A, a support D extending laterally of said portion A and secured thereto, a tubular portion pivotally secured to said portion A by pivots *d d*, the longitudinal axis of said pivots lying in substantially a vertical plane whereby said chute is vertically rigid and laterally flexible, for the purpose described.

6. A flexible chute comprising, a main portion A, and a series of tubular sections pivotally secured to each other and to said portion A by pairs of pivots, the longitudinal axes of each pair of pivots lying in a vertical plane whereby said chute is vertically rigid and laterally flexible, and means for positively locking said sections in various laterally-adjusted positions for the purpose described.

7. A flexible chute comprising a main portion A having a flat bottom A′ and side portion A^2, a bar or support D rigidly secured to said portion A, a taper tubular portion pivotally secured to said portion A by rivets or bolts *d, d*, the longitudinal axes of said rivets or bolts lying in a line perpendicular to the plane of the bottom portion A′ for the purpose described.

8. A flexible chute comprising sections angularly adjustable relative to each other and resilient means normally maintaining the longitudinal axes of said sections in alinement.

9. A flexible chute comprising a series of sections pivotally secured to each other and resilient means normally maintaining the longitudinal axes of said sections in alinement.

10. A flexible chute comprising a series of sections pivotally secured to each other, a perforated bag carried by each section, and a resilient rod extending through said perforated bags, substantially as described.

11. A flexible chute comprising a main body portion, a series of sections pivotally secured to each other and to said body portion, a perforated bag carried by each section at a distance from said pivot, and a resilient rod extending through said perforated bags, and secured at its end to said body portion substantially as described.

12. A flexible chute comprising sections angularly adjustable relative to each other and means for locking said chutes in various adjusted positions including a device secured to one end section and a retaining means for adjustably securing said device to the other end section substantially as described.

13. A flexible chute comprising sections pivotally secured to each other whereby said sections may be angularly adjusted, means for maintaining said sections in alinement and means for locking said sections in various adjusted positions substantially as described.

14. A flexible chute comprising end sections and intermediate sections pivotally secured to each other and means for locking said chute in various adjusted positions including a rod pivotally secured to one of said end sections, a swiveled fulcrum-block secured to the other end section and loosely receiving said rod and means carried by said latter end section for locking said rod against lateral movement, substantially as described.

708,082. CHUTE. FRANK L. SACKETT, Fredonia, N. Y. Filed Mar. 17, 1902. Serial No. 98,478. (No model.)

Claim.—1. A chute comprising an open-top body portion and a supporting-bail pivotally attached adjacent to one end of said body portion, said pivots being so disposed relatively to the body portion and the bail that said bail may be turned above the chute-body or below the same substantially as described.

2. A chute comprising a body portion having a flat bottom portion and sides substantially at right angles thereto, a bail having a portion parallel to said bottom portion and end portions, and pivots for securing said end portions of the bail to said sides of the body portion for the purpose described.

3. A chute comprising a body portion having a flat bottom portion and sides substantially at right angles thereto, a strengthening-band at one end thereof, and a bail having a portion parallel to said bottom portion and end portions, pivots for securing the end portions to said sides, said pivots being so disposed that said bail may be turned above the chute-body or below the same, substantially as described.

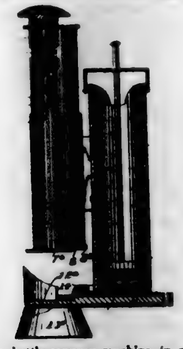
4. A chute comprising a body portion, a strengthening-band around the end thereof, a hook having a portion thereof secured between said band and body portion, and a portion at right angles to the body portion, and a bail pivotally secured to the strengthening-band and chute-body, substantially as set forth.

5. A chute comprising a body portion, a strengthening-band around the end thereof, a hook having a portion thereof secured between said band and body portion and a portion at right angles thereto, a bail having a portion substantially parallel to the bottom of the chute and bent at its end and pivotally secured to said strengthening-band, substantially as set forth.

6. A chute comprising a body portion, a strengthening-band around the end thereof, a series of strips extending longitudinally of the body portion of the chute and secured beneath said band, a supplemental band extending transversely of said chute and securing the other end of said strips, substantially as set forth.

7. A chute comprising a body portion, a strengthening-band around the end thereof, a series of strips extending longitudinally of the body portion of the chute and secured beneath said band, a supplemental band extending transversely of said chute and securing the other end of said strips, a bail having a portion substantially parallel to the bottom of the chute and pivotally secured at its ends to the sides of said chute, substantially as set forth.

708,083. BOTTLE-CAPPING MACHINE. JAMES D. SCHELL, Evanston, Ill. Filed Dec. 23, 1901. Serial No. 86,851. (No model.)



Claim.—1. In a bottle-capping machine, in combination, a vertically-reciprocating spring-supported plunger, a magazine-tube adjacent thereto, a reciprocating plunger-actuated disk-carrier under the mouth of the tube, adapted to carry a disk to a position beneath the plunger, and a detent to prevent backward movement of the disk when the carrier recedes.

2. In a bottle-capping machine, the combination with disk-feeding means, of a support, a reciprocating spring-supported plunger therein comprising telescoping tubes combined relative to each other, one of said tubes having a plunger-head and the other a handle, and connections between the plunger and the feeding means to cause cooperative action.

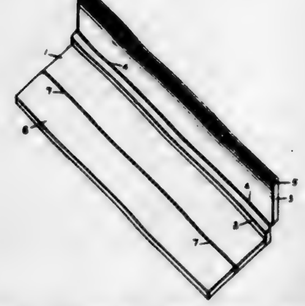
708,084. TOY-CARTRIDGE EXPLODER. ROBERT I. SHOUP, Cleveland, Ohio, assignor to the Cleveland Toy and Manufacturing Company, Cleveland, Ohio, a Corporation of Ohio. Filed Oct. 1, 1901. Serial No. 77,220. (No model.)

Claim.—1. In a cartridge-exploder, in combination, an upper member having on diametrically opposite sides horizontal walls, a lower member having in its outer face a downwardly-opening diametric groove extending across the bottom and up the sides of said member, a U-shaped bail occupying said grooves and having its ends extending through openings in said walls in the upper member and having upset heads, and a spring tending to bring said members together, substantially as described.

2. In a cartridge-exploder, in combination, an upper member having in its upper end a recess for the reception of a stick and in its lower end a recess opening downward and opening sidewise, a lower member having a projection adapted to enter the bottom recess of the upper member, and having in its outer face a downwardly-opening diametric groove extending across the bottom and up the sides of said member, a U-shaped bail riveted at its ends to said upper member and occupying said grooves in the bottom and sides of said lower member, and a spring tending to bring said members together, substantially as described.

3. In a cartridge-exploder, an upper member A formed in conical shape and having a recess in its upper end for the reception of a stick and a flaring recess a' in its lower end, which latter recess also has a lateral opening a^2, there being a pair of recesses a^1 a^2 on opposite sides of the member, combined with a cooperating member B having on its upper surface a conical projection adapted to enter the recess a', said member B having a diametrical groove *b*, a bail D depending from the member A by having its ends projecting through the member into the recesses a^2 and there riveted, said bail occupying the groove *b*, and a spring occupying a central downwardly-opening recess in the member B and bearing against the inner surface of the bail, substantially as described.

708,085. CIGAR-SHAPER. CHRISTIAN G. SINGLEY, Manheim, Pa. Filed July 16, 1902. Serial No. 115,751. (No model.)



Claim.—1. The combination, in a cigar-shaper, of a bottom plate, a back on the bottom plate, a lid hinged to the back, and a shaping-plate hinged to the front of the bottom plate, for the purpose specified.

2. The combination, in a cigar-shaper, of a bottom plate, a back on the bottom plate, a lid hinged to the back, means for securing the lid in a closed position, and a shaping-plate hinged to the front of the bottom plate, for the purpose specified.

3. The combination, in a cigar-shaper, of a bottom plate, a back on the bottom plate, a lid hinged to the back and having the swinging edge thereof beveled, and a shaping-plate hinged to the front of the bottom plate, for the purpose specified.

4. The combination, in a cigar-shaper, of a bottom plate, a back on the bottom plate, a lid hinged to the back, means for securing the lid in a closed position, a shaping-plate hinged to the front of the bottom plate, and means for securing the shaping-plate in a raised position, for the purpose specified.

5. The combination, in a cigar-shaper, of a bottom plate, a back on the bottom plate, a lid hinged to the back and having the swinging edge thereof beveled, the hook 10 and the staple 11, a shaping-plate hinged to the front of the bottom plate, and the hooks 12 and the staples 13, for the purpose specified.

708,086. PRINTER'S FURNITURE. WILLIAM G. HANSEN, Ossa, N. Y. Filed Nov. 1, 1902. Serial No. 726,908. (No model.)

Claim.—1. A hollow rectangular metallic bar of printers furniture, having a side opening, and an inclosed quoin, and means for projecting said quoin from the opening, or for retiring the quoin entirely within the opening.

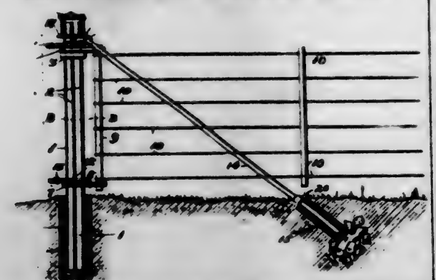
2. A hollow rectangular metallic bar of printers' furniture, having a side mortise, a quoin in said mortise which may be retired entirely within the bar, a wedge within the bar engaging the quoin, and means for moving the wedge.

3. A hollow rectangular metallic bar of printers' furniture having a mortise in one side, a quoin in said mortise in position to be withdrawn wholly within the bar, and a wedge within the bar having interlocking engagement with the quoin, so that longitudinal movement of the wedge advances or retracts the quoin.

4. A rectangular metallic bar of printers' furniture having a side mortise and a face opening in one face only, a quoin in the mortise which may be retired entirely within the bar, means within the bar for projecting the quoin, and a wrench which may enter the face-opening to engage the quoin-projecting means, but may not reach through the body of the bar, all combined.

5. A hollow rectangular bar of printers' furniture having a plurality of side mortises, quoins in said mortises, and independent means for retiring said quoins within the bar, or for projecting them, all combined.

708,087. BRACED FENCE-POST. WILLIAM H. SMITH, New Cumberland, W. Va., assignor of one-half to George A. McCandless, Oakdale, Pa. Filed Dec. 23, 1901. Serial No. 86,966. (No model.)

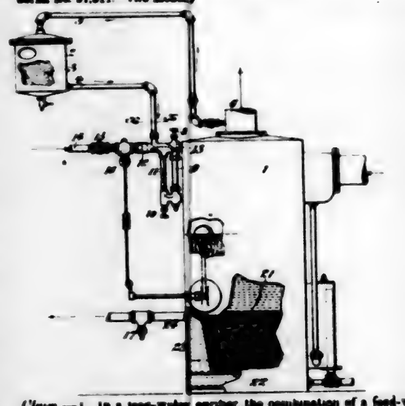


Claim.—1. In combination with a wire fence, a braced post comprising a tubular metal post-body having an adjustable cap fitted to its upper end and a tubular non-rotting or non-rusting base secured to the buried end, a two-legged V-shaped brace circumferentially engaging said post beneath the cap and extending therefrom at an inclination in the direction of and to straddle the fence with tubular non-rotting or non-rusting base-pieces secured to the buried ends thereof, links carried by said post extending laterally therefrom in a line with the fence, and a rod loosely fitted into said links to engage the fence-wires, as shown and set forth.

2. In combination with a wire fence, a braced fence-post comprising a tubular metal post having an adjustable cap fitted to its upper end and a tubular non-rotting or non-rusting base-piece secured to the buried end, a two-legged V-shaped brace circumferentially engaging said post beneath the cap and extending therefrom at an inclination in the direction of and to straddle the fence with tubular non-rotting or non-rusting base-pieces secured to the buried ends thereof, links carried by said post extending laterally therefrom in a line with the fence, a rod loosely fitted into said links to engage the fence-wires, and laterally-extended gate-suspending members carried by said post, as shown and set forth.

3. In combination with a wire fence, a braced post comprising a tubular metal post-body having an adjustable cap fitted to its upper end and a tubular non-rotting or non-rusting base-piece secured to the buried end, a plurality of two-legged V-shaped braces circumferentially engaging said post beneath the cap and extending therefrom at an inclination in the direction of and to straddle the fence leading thereto and having non-rotting or non-rusting base-pieces secured upon their buried ends, links carried by said post extending laterally therefrom in line with the fence, and rods loosely fitted into said links to engage the fence-wires, as shown and set forth.

708,088. SYSTEM OF FEED-WATER PURIFICATION. ADOLPH SUTRO, Jr., Chicago, Ill. Filed Mar. 2, 1896. Renewed Mar. 12, 1902. Serial No. 97,811. (No model.)



Claim.—1. In a feed-water purifier, the combination of a feed-water heater, a closed tank containing a purifying ingredient, a pipe leading from the steam-space of said heater into the upper portion of said tank whereby the water of condensation passes through said tank and purifying ingredient in its path to said heater, a feeding device, a pipe leading from said tank to said feeding device and a feed-water inlet-pipe communicating with said feeding device, the latter being connected with said heater.

2. In a feed-water purifier, the combination of a feed-water heater, a tank containing a purifying ingredient, a pipe leading from the steam-space of said heater into the upper portion of said tank, a feeding device, a pipe leading from said tank to said feeding device, a feed-water inlet-pipe communicating with said feeding device, a connection from the latter to said heater, a filtering device for the water in said heater and a pipe for conducting the filtered and purified water from said heater, said last-mentioned pipe having therein means for drawing off and testing the water prior to its entrance into the boiler.

3. In a feed-water purifier, a feed-water heater having an outlet leading to a boiler, a tank containing a purifying ingredient, said tank communicating with the heater by a plurality of pipes, one of said pipes communicating with the steam-space of said heater, whereby steam passes therefrom into said tank to be condensed therein, said parts being so constructed that the water of condensation passes through the tank and purifying ingredient therein and returns to said heater, and a filter through which the water passes between said heater and said boiler.

4. In a feed-water purifier, a feed-water heater, a tank containing a purifying ingredient, a pipe communicating with the upper portion of said tank and with the steam-space of said heater, another pipe communicating with said tank and with said heater, a filtering device within said heater, consisting of a plurality of filtering-beds, a passage or chamber in which the filtered water is received, and an outlet-pipe leading therefrom.

5. The combination of a feed-water heater, a closed tank containing a purifying ingredient, a pipe leading from the steam-space of said heater into the upper portion of said tank, whereby the water of condensation passes through said tank and purifying ingredient in its path to said heater, a feeding device, a pipe leading from said tank to said feeding device, a feed-water inlet-pipe communicating with said feeding device, the latter being connected with said heater, a filtering device in the lower portion of said heater, and an outlet-pipe for the filtered water.

6. The combination of a feed-water heater, a closed tank containing a purifying ingredient, a pipe leading from the steam-space of said heater into the upper portion of said tank, whereby the water of condensation passes through said tank and purifying ingredient in its path to said heater, a feeding device, a pipe leading from said tank to said feeding device, a feed-water inlet-pipe communicating with said feeding device, the latter being connected with said heater, a filtering device in the lower portion of said heater, and an outlet-pipe for the filtered water, in combination with means for testing the purified and filtered water prior to its entrance to the boiler.

708,089. BICYCLE-BRAKE. GIOACCHINO STABILE, San Francisco, Cal., assignor of two-thirds to Joseph C. Sala and Armand Maurice Vivier, San Francisco, Cal. Filed Apr. 14, 1902. Serial No. 102,779. (No model.)

Claim.—1. A steering-head for a bicycle comprising a middle section constituting a rigid member of the steering-post, outer sections connected to the middle section at opposite ends by hinge-joints, said outer sections having limited angular movement of their hinge-joints toward each other in one direction under an inward pressure, but to be rigid and in line with the middle section under pressure applied in the opposite direction, and means connected with said hinged sections operating under the angular movement thereof in one direction to grip the rim of the wheel from opposite sides, and to release the wheel by their movement in the contrary direction.

2. In a bicycle-brake, a steering-head comprising a rotatable post having a cross-head fixed on the upper end, handle-bearing outer members attached to the outer ends of the cross-head by hinge-joints, said handle-bearing members having limited angular movement only in one direction and rigid under pressure applied to the handles in all other directions; in combination with brake-arms having angular movements with respect to the rim of the steering-wheel and adapted to grip the wheel from opposite sides of the rim, and means rigidly connecting said brake-arms with the handle-bearing members, whereby the angular movements of the handle-bars produce corresponding angular movements of the brake-arms to close the latter upon the wheel, and a spring at the joint of each handle-bearing member adapted to bring said member to position when pressure is removed therefrom and throw off the brake-arms.

708,090. SHADE-ROLLER-HANGING APPARATUS. JEREMIAH STOUFFBAKER, Barnesville, Ohio. Filed Mar. 3, 1900. Serial No. 7,071. (No model.)

Claim.—The combination with a window, of pulleys mounted on the window-frame at opposite sides of the top thereof, the cord 5 doubled between its ends to form a depending loop and arranged on and extending downward from each of the said pulleys, a shade-roller, and the shade-roller brackets each constructed of a single piece of wire coiled at its upper end and at its center to provide upper and lower eyes for the reception of the ends of the cord, said bracket being provided at its lower portion with a U-shaped bend or loop for the reception of the journal of the shade and the lower terminal of the wire being arranged directly beneath the lower eye, whereby the loop is closed to confine the journal therein, substantially as described.

708,090.

708,091. ROTARY HAND-FAN. BENNETT D. STRAIGHT, Chicago, Ill. Filed Oct. 7, 1901. Serial No. 77,801. (No model.)

Claim.—1. A rotary hand-fan comprising a handle, a fan supported on a shaft mounted to rotate in the handle, a cord wrapped around the shaft and secured at one end to the handle through an elastic connection, a lever pivoted to the handle and having its free end secured to the other end of the cord, and elastic means applied to normally hold the lever against the handle, substantially as described.

2. A rotary hand-fan comprising a handle, a fan supported on a shaft mounted to rotate in the handle, a cord wrapped about the shaft and secured at one end to the handle through an elastic connection, and a lever pivoted to the handle and secured at its free end to the other end of the cord, said lever being provided with a bow-shaped bend near its pivoted end, substantially as described.

3. A rotary hand-fan comprising a handle, a fan supported on a shaft mounted to rotate in the handle, a cord wrapped about the shaft and secured at one end to the handle through an elastic connection, and a lever pivoted to the handle and secured at its free end to the other end of the cord, said lever being provided with a bow-shaped bend near its pivoted end, and elastic means applied between the handle and lever to normally force the bow portion of the lever away from the handle, substantially as described.

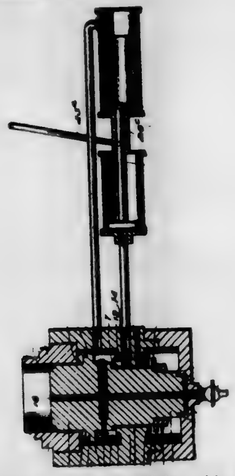
708,092. AIR-BRAKE VALVE. FREDERICK STRATTNER, Salisbury, Md. Filed Oct. 15, 1901. Serial No. 78,742. (No model.)

Claim.—1. In air-brake apparatus, an air-cylinder and its piston for applying the brake, an air-storage cylinder and its piston arranged for simultaneous coaction with the first-referred-to piston, for releasing the brake, and air-pressure valve mechanism operatively connected to the train-pipe and to said cylinders, comprising a primary valve and an automatic supplemental valve carried by, and independently operative of, said primary valve, substantially as set forth.

2. In air-brake apparatus, an air-cylinder and its piston for applying the brake, an air-storage cylinder and its piston having a relatively reduced area or diameter and arranged for simultaneous coaction with the aforesaid piston, for releasing the brake, and air-pressure valve mechanism operatively connected to the train-pipe and to said cylinders, comprising a primary valve and an automatic supplemental valve carried by, and independently operative of, said primary valve, substantially as set forth.

3. In air-brake apparatus, an air-cylinder and its piston for apply-

ing the brake, an air-storage cylinder and its piston arranged for simultaneous operation with the aforesaid piston for releasing the brake, and an air-pressure valve mechanism operatively connected with said cylinders comprising a primary valve and an automatic supplemental valve carried by, and independently operative of, said primary valve, said primary valve having a port or passage therethrough intersected by said supplemental valve, substantially as set forth.



4. In air-brake apparatus, an air-cylinder and its piston for applying the brake, an air-storage cylinder and its piston arranged for simultaneous operation with the first-named piston, for releasing the brake, air-pressure valve mechanism, comprising a primary valve and an automatic supplemental valve carried by, and independently operative of, said primary valve, and adapted to be seated at each end, said primary valve having a port or passage therethrough intersected by said supplemental valve, pipe connection with said cylinders, and means establishing communication between said pipe connection and the ports of said primary and supplemental valves, substantially as set forth.

5. In air-brake apparatus, an air-cylinder and its piston, for applying the brake, an air-storage cylinder and its piston for releasing the brake, an air-pressure valve mechanism, means for effecting operative connection between said cylinders and valve mechanism, comprising a primary valve and an automatic supplemental valve carried by, and independently operative of, said primary valve, said piston having a common rod connection, substantially as set forth.

6. In air-brake apparatus, an air-cylinder and its piston, for applying the brake, an air-storage cylinder and its piston for releasing the brake, an air-pressure valve mechanism means for effecting operative connection between said cylinder and valve mechanism, comprising a primary valve and an automatic supplemental valve carried by, and independently operative of, said primary valve, said pistons being of different diameters and having a common rod connection, substantially as set forth.

7. In air-brake apparatus, an air-cylinder and its piston, for applying the brake, an air-storage cylinder and its piston, an air-pressure valve mechanism, means for effecting operative connection between said cylinders and valve mechanism, said valve mechanism having its valve proper supplied with supplemental or compensating valve acting in conjunction with a central port or passage of said valve proper and a second compensating valve also cooperating with said valve proper, said compensating valve effecting the direct supply of air-pressure to said brake-cylinder, and one effecting a passage between the bottom outlet of said central valve-port and said storage-cylinder, substantially as set forth.

8. In apparatus of the character described, a brake-applying cylinder and its piston, a brake-releasing cylinder and its piston, air-pressure valve mechanism, means effecting operative connection between said cylinders and valve mechanism, said valve mechanism comprising a centrally-ported valve, having a plurality of lateral contacting surfaces within its casing and two supplemental or compensating valves arranged for conjoint operation and in communication with ports in said casing and with said cylinders, substantially as set forth.

9. In air-brake apparatus, a brake-applying cylinder and its piston, an air-pressure-storage cylinder and its piston, a valve mechanism, and means for effecting operative connection between said cylinders and said valve mechanism, said mechanism comprising a casing having an inward circular extension, a collar provided with a circular pendent projection, and a bottom portion having, around a depression or recess therein, a shoulder, said inward extension having projections upon its upper and lower surfaces, a centrally-ported valve, having lateral vertical ports and corresponding salient portions with those of said casing, above noted, adapted to contact with, or engage the same, two supplemental or compensating valves, one adapted to be seated in the first-named valve and the other in said casing, said casing also having ports connecting with said cylinders and lateral ports of the first-referred-to valve, and an air-exhausting port, substantially as set forth.

708,093. ELECTRICALLY-PROTECTED STRUCTURE. HENRY M. SUTTON, WALTER L. STEELE, and MICHAEL CORRYER, Dallas, Tex. Original application filed May 20, 1901, Serial No. 61,923. Divided and this application filed Aug. 19, 1901. Serial No. 72,573. (No model.)

Claim.—1. In an electrical alarm system, a wiring for a protected structure comprising a series of wires each composing an independent circuit, one of said series extending at a right angle to the other and the third series intersecting diagonally the spaces between the first two series of wires; substantially as specified.

2. A wiring for a protected structure comprising a block or body having on one face intersecting kerfs or grooves therein extending at a right angle to each other and of different depths, and an electrical conductor in each of said kerfs or grooves; substantially as specified.

3. A wiring for a protected structure comprising a block or body having intersecting kerfs or grooves therein of different depths, and an electrical conductor in each of said kerfs or grooves; substantially as specified.

4. In an electrical alarm system, a casenet or apartment having the several walls or surfaces thereof provided with intersecting grooves of different depths lined by superposed insulated electrical conductors in continuous circuit; substantially as specified.

5. In an electrical alarm system, a cabinet or apartment having the several walls or surfaces thereof provided with intersecting grooves of different depths lined by superposed electrical conductors in continuous circuits, and insulated material for embedding each layer of said conductors; substantially as specified.

6. An electrical alarm system, a block or body having a series of grooves therein of different depths extending at right angles to each other and diagonally across the spaces between the right-angle grooves, circuit-wires located in said grooves and insulated from each other, and means for establishing circuits through said wires; substantially as specified.

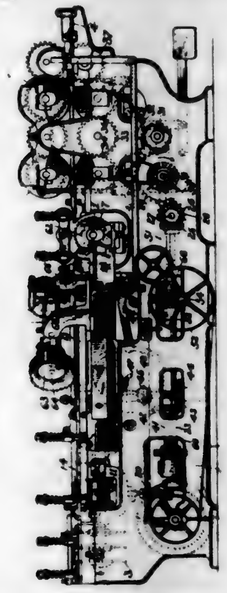
708,094. MACHINE FOR MAKING FIRE-LIGHTER BLOCKS. JOHN B. THOMAS, Cincinnati, Ohio, assignor to Pollard & Metcalfe, Limited, Bledon, England. Filed Jan. 9, 1902. Serial No. 88,062. (No model.)

Claim.—1. In combination, a saw or gang of saws for grooving the stock longitudinally, a second saw or gang of saws for grooving the stock transversely, a cut-off saw for severing the grooved stock into blocks, feeding means for the stock, a mutilated gear, means for driving the same and a pair of gears driven alternately by the mutilated gear, connections from one of said gears to the feeding mechanism and connections from the other of said gears to the cut-off saws, substantially as described.

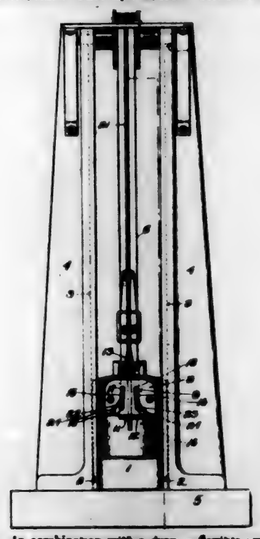
2. In combination, a saw or gang of saws for grooving the stock longitudinally, a second saw or gang of saws for grooving the stock transversely, a cut-off saw for severing the grooved stock into blocks, feeding means for the stock, a mutilated gear, means for driving the same and a pair of gears driven alternately by the mutilated gear, connections from one of said gears to the feeding mechanism, connections from the other of said gears to the cut-off saws, and means for driving the transverse saws from the connections leading to the cut-off saws, substantially as described.

3. In combination, a saw or saws for grooving the stock longitudinally, a saw or saws for grooving it transversely, a cut-off saw for severing the grooved stock into blocks, feeding mechanism for the stock, a mutilated gear, means for driving the same, a pair of gears, connections therefrom for driving respectively the feeding means and the cut-off saws alternately and means whereby the shafts of said gears may be adjusted to provide change-gearing, substantially as described.

4. In combination with intermittent feeding means, longitudinal saws with means for driving the same, transverse and cutting-off saws, a mutilated gear, a connection therefrom to the intermittent feeding means to operate the same, connections between the mutilated gear and the transverse and cutting-off saws whereby the same are operated against the stock intermittingly, said means including a gear meshing with the mutilated gear, beveled gearing, a shaft to which one member of the beveled gearing is splined and an adjustable bracket for adjusting the splined gear together with its shaft toward and from the mutilated gear, substantially as described.



708,095. SAFETY DEVICE FOR STAMPS, DROP-HAMMERS, OR THE LIKE. CHARLES A. THORNTON and CHARLES W. WHITTEMORE, North Attleboro, Mass. Filed Apr. 26, 1902. Serial No. 104,736. (No model.)



Claim.—1. In combination with a drop, a flexible strap by which said drop is raised, and a safety device to check accidental descent of said drop, said safety device comprising movable jaws attached to the drop, a fixed rod, a safety-line which connects said jaws with the operating end of the lifting-strap and which temporarily receives the strain of the drop when the main strap is broken or otherwise disconnected at a point intermediate of its operating end and its connection with the drop, the strain upon the safety-line actuating the jaws to grip the said fixed rod, substantially as described.

2. In combination with a drop, a flexible line by which said drop is raised, and a safety device comprising a wedge-shaped way on said drop, slidable jaws mounted to move in said way, a fixed rod which passes between said jaws, and a flexible connection between said jaws and the operating end of said lifting-line, which if said lifting-line breaks or is otherwise disconnected at an intermediate point will receive the strain from the drop and move the said jaws to grip the said rod and stop the descent of the drop, substantially as described.

3. In combination with a drop, a lifting-strap one end of which is secured to said drop, and a safety device comprising slidable jaws attached to said drop, a fixed rod which passes between said jaws, springs which normally prevent the jaws from gripping said rod, and a connection between said jaws and said lifting-strap which will receive the strain of the weight of the drop if the said strap is broken or otherwise disconnected at an intermediate point between its operating end and connection with the drop, and thereby set the jaws into engagement with the said fixed rod, substantially as described.

4. In combination with a drop-hammer, a strap attached thereto and a support over which said strap passes whereby said hammers may be raised by the strap, and a safety device comprising a way of inverted-wedge shape on the hammer, movable jaws in said way, a plate covering said jaws, guide-slots in said plate inclined toward each other upwardly, guide-pins which project from said jaws through said guide-slots, a fixed rod passing between said jaws, and a flexible safety-line which connects said jaws with said lifting-strap at the operating end thereof and receives the strain of the hammer if the lifting-strap is broken or otherwise disconnected at any point between the hammer and the point where the safety-line is connected with the said strap and will cause the jaws to grip the said fixed rod and stop the descent of the hammer, substantially as described.

5. In combination with a drop, a flexible strap or line one end of which is secured to said drop, and a pulley mounted above the said drop over which said strap runs whereby said drop may be raised and dropped, and a safety device to stop the descent of said drop if said strap or line breaks, said safety device comprising a slotted way of inverted-wedge shape on said drop, movable wedge-shaped jaws in said slot, a fixed rod which passes down between said jaws, a face-plate covering said jaws and slotted ways having guide-slots inclining upwardly toward each other, guide-pins on said jaws which extend into said guide-slots whereby movement of said jaws upwardly relative to the slots will cause the jaws to grip said rod, and a connection between said jaws and said strap or line, whereby if said strap or line breaks at an intermediate point between the drop and the point where said connection is attached to said strap the jaws will be caused to grip said rod and stop the descent of the drop, substantially as described.

6. In combination with a drop-hammer, a strap by which said hammer is raised and lowered, and a safety device to prevent accidental falling of the hammer, said safety device comprising a pair of gripping-jaws carried by the hammer, a fixed rod adapted to be engaged by said jaws, a flexible connection between said jaws and said strap whereby if the said strap is broken or otherwise disconnected at a point between the connection with the hammer and its operating end the hammer will then pull upon said flexible connection with the jaws and cause them to grip said rod and check the descent of the hammer, substantially as described.

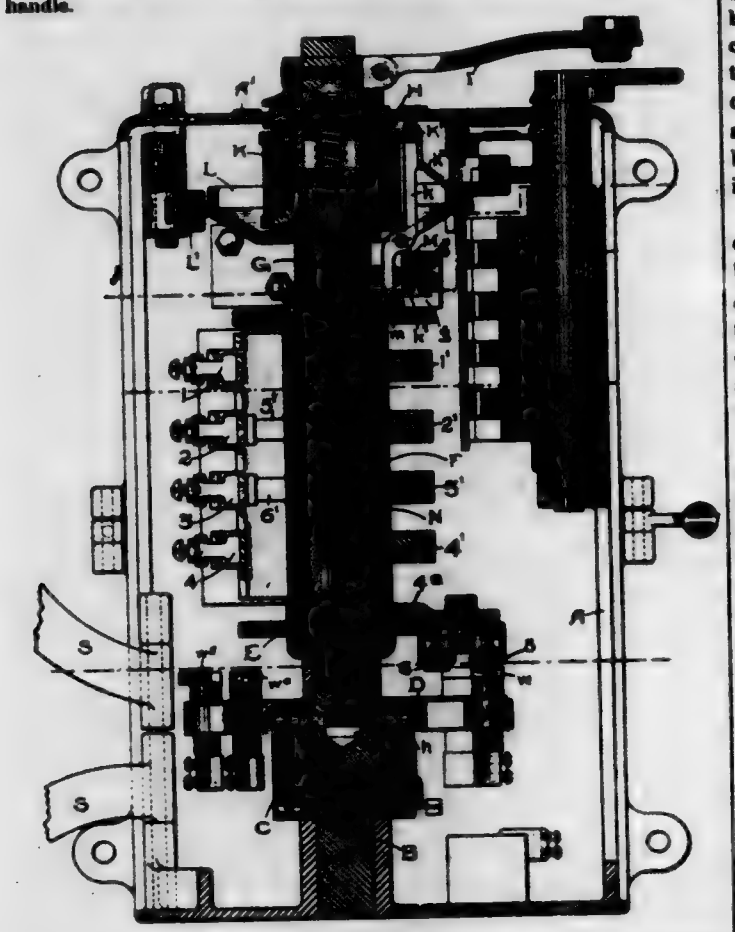
708,096. CONTROLLER FOR ELECTRIC MOTORS. LEONARD A. TERRILL, Lynn, Mass., assignor to General Electric Company, a Corporation of New York. Filed Feb. 14, 1901. Serial No. 47,198. (No model.)

Claim.—1. In a controller, a rotatable contact-carrying member, a handle for operating said member, an electromagnet concentric with the shaft on which said handle is mounted, an armature for said electromagnet operatively connected to the controller-handle so as to be rotated therewith in a path concentric with the periphery of the electromagnet, and means controlled by said armature for locking the handle to the contact-carrying member.

2. In a controller, a rotatable contact-carrying member, a handle for operating said member, an electromagnet concentric with the shaft on which said handle is mounted, an armature for said electromagnet operatively connected to the controller-handle so as to be rotated therewith in a path concentric with the periphery of the electromagnet, means controlled by said armature for locking the handle to the contact-carrying member, and means for returning the said member to its initial position whenever it is unlocked from the handle.

3. In a controller, a rotatable contact-carrying member, a handle for operating said member, an electromagnet concentric with the shaft on

which said handle is mounted, and an armature for said magnet operatively connected with the controller-handle so as to be rotated therewith in a path concentric with the periphery of the electromagnet, the said armature operating in one position to lock the rotatable member to the controller-handle and in another position to unlock the said member from the handle.



4. In a controller, a rotatable contact-carrying member, a handle for operating said member, an electromagnet concentric with the shaft on which said handle is mounted, an armature for said magnet operatively connected with the controller-handle so as to be rotated therewith in a path concentric with the periphery of the electromagnet, the said armature operating when the magnet is energized to lock the rotatable member to the controller-handle, and a spring for moving the armature to unlock the member from the handle when the magnet is deënergized.

5. A controller for an electric motor, comprising a rotary tubular shaft, a contact-cylinder secured thereto, a handle sleeved on the shaft, means for locking the handle to the shaft, an electromagnetic device for unlocking them, and a coiled spring in said tubular shaft attached to the shaft and the handle.

6. A controller for an electric motor, comprising a rotary shaft, a contact-cylinder secured thereto, an arm moving with said cylinder, a catch-plate on the arm, a handle sleeved on the shaft and carrying a pawl adapted to engage with the catch-plate, and an electromagnetic device for actuating the pawl.

7. A controller for an electric motor, comprising a contact-cylinder and shaft, an arm moving with the cylinder and carrying a catch-plate, a handle sleeved on the shaft and carrying a star-wheel and an electromagnet, a pawl pivoted on the star-wheel and adapted to engage with the catch-plate, and an armature for the electromagnet arranged to disengage said pawl.

8. In a controller, the combination with a rotatable member, of a plurality of circuit-controlling contacts arranged alongside of said member, a plurality of resistance-controlling contacts arranged concentric with said member, cylindrical contacts carried by said rotatable member and adapted to remain in engagement with the circuit-controlling contacts in all the power positions of the controller, and a brush contact or contacts electrically connected to one of the contacts on said rotatable member and adapted to successively engage the concentrically-arranged contacts.

9. In a controller, a rotatable member provided with cylindrical contacts, fixed contacts arranged to be engaged thereby, a supporting-frame located beneath the said rotatable member, a series of contacts mounted thereon in a circle concentric with the axis of rotation of said rotatable member, and a contact on the rotatable member arranged to successively engage the contacts of the said series as the said member is rotated.

10. In a controller, a set of fixed contacts arranged one above another, a rotatable member provided with cylindrical circuit making and breaking contacts adapted to engage said fixed contacts, one or more series of circuit-controlling contacts mounted in a circle concentric with the axis of rotation of said rotatable member, and one or more contact-fingers mounted on said rotatable member and arranged to successively engage the contacts of the said series, as the said member is rotated, without opening the circuit at said contacts.

11. In a controller, a set of fixed contacts arranged one above another, a rotatable member provided with cylindrical circuit making and breaking contacts adapted to engage said fixed contacts, a series of circuit-controlling contacts mounted in a circle concentric with the axis of rotation of the said rotatable member, a coöperating contact-finger mounted on said rotatable member and electrically connected to the circuit making and breaking contacts, and means for extinguishing any arc which may be formed on the opening of the circuit at the circuit making and breaking contacts.

12. In a controller, a set of fixed contacts arranged one above another, a rotatable member provided with cylindrical circuit making and breaking contacts adapted to engage said fixed contacts, a series of circuit-controlling contacts mounted in a circle concentric with the axis of rotation of the said rotatable member, a coöperating contact-finger mounted on said rotatable member and electrically connected to the circuit making and breaking contacts, and a blow-out magnet for the circuit making and breaking contacts.

13. In a controller, a set of fixed contacts arranged one above another, a rotatable member provided with cylindrical circuit making and breaking contacts adapted to engage said fixed contacts, a second set of fixed contacts rigidly mounted in a circle concentric with the axis of rotation of the said rotatable member, and a yieldably-supported brush or contact-finger adapted to successively engage the contacts of the said second set, the said brush or contact being mounted on said rotatable member and electrically connected to the circuit making and breaking contacts thereon.

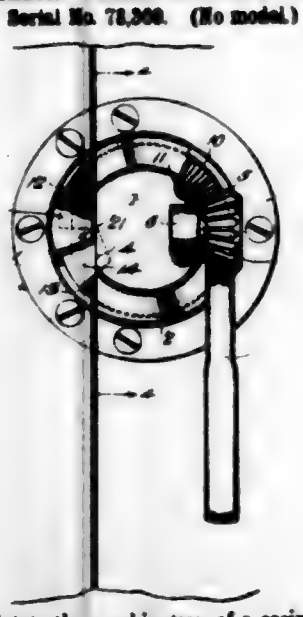
14. In a controller for an electric motor, the combination with a stationary post, of a frame supported thereon carrying one or more series of contact-plates concentric with said post, a contact-cylinder having its shaft journaled on the upper end of said post, and an arm on said cylinder carrying one or more contact-fingers to engage with said plates.

15. In a controller for an electric motor, the combination with a stationary post, of a blow-out coil concentric therewith, and a contact-cylinder having its shaft stepped in the upper end of said post.

16. The combination with a compound-wound electric motor, of a resistance in series with the series field-coil, a second resistance, and a single switch mechanism for successively cutting out the series resistance and throwing the second resistance in shunt around the series field-coil.

17. The combination with a compound-wound electric motor, of two resistances, and a single switch mechanism for successively connecting one of said resistances in series with the series field-coil, gradually cutting out said resistance, throwing the second resistance in shunt around said series field-coil, and finally gradually cutting out said second resistance.

708,097. LATCH. DANIEL W. TOWER, Grand Rapids, Mich.
Filed Oct. 11, 1901. Serial No. 78,209. (No model.)



Claim.—1. In a latch, the combination of a casing, a rotatable bolt mounted therein having a locking-head and a toothed segment, an operating-handle with a toothed head engaging the said segment, the toothed head of the handle being at an angle to the bolt, and a striker having a keeper for engagement by the bolt-head.

2. In a latch, the combination of a casing, a rotatable bolt having a locking-head and a toothed segment, an operating device disposed at an angle to the bolt and having a toothed head to engage said segment, and a striker having a keeper for engagement by said bolt-head.

3. In a latch, the combination of supporting means, a rotatable bolt having a locking-head and toothed segment, an operating device for the bolt movable in a plane at right angles to the latter and having a toothed head to engage said segment, and a striker for engagement by said bolt-head.

4. In a latch, a rotatable bolt, a striker to engage a portion of the bolt, and means movable in planes at right angles to the movement of the bolt for operating the latter.

5. In a latch, the combination with a keeper, of a rotatable bolt having a portion to engage said keeper and provided with a toothed segment, and a vertically-movable operating means having a toothed head to engage said segment, the bolt being movable in a plane at an angle to that of said operating means.

6. In a latch, the combination with a striker, of a rotatable bolt having means to engage said striker movable concentrically therewith, and an operating device for the said bolt movable in a plane at an angle to the latter.

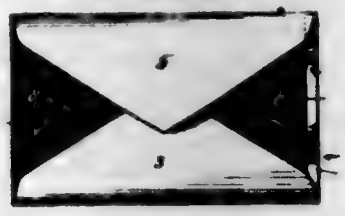
7. In a latch, the combination of a striker having a reversible keeper, a rotatable bolt having two heads spaced apart and arranged to engage opposite portions of the keeper, and reversible means movable in planes at right angles to the movement of the bolt for operating the latter, substantially as described.

8. In a latch, the combination of a striker having a diagonally-arranged keeper and adapted to be reversed, a rotatable bolt provided with a pair of heads spaced apart to engage opposite portions of the keeper, and reversible means movable in planes at right angles to the movement of the bolt for operating the latter, substantially as described.

9. In a latch, the combination of a striker having a diagonally-disposed keeper, a rotatable bolt provided with reversely-tapered heads spaced apart and arranged to engage the opposite faces of the diagonally-disposed keeper, the latter being adapted to be reversed to enable either of the said heads to extend behind it, and reversible means for operating the bolt, substantially as described.

10. In a latch, the combination of a striker having opposite engaging faces, a rotatable bolt with a pair of contiguous heads to individually engage the faces of the said keeper and also having a toothed segment, and an operating-handle revolubly and reversibly mounted in relation to the bolt and having a head in the form of a bevel-pinion to engage the said segment.

708,098. ENVELOP. GEORGE D. VAN ARSDALE, Newark, N. J. Filed Dec. 12, 1901. Serial No. 85,504. (No model.)



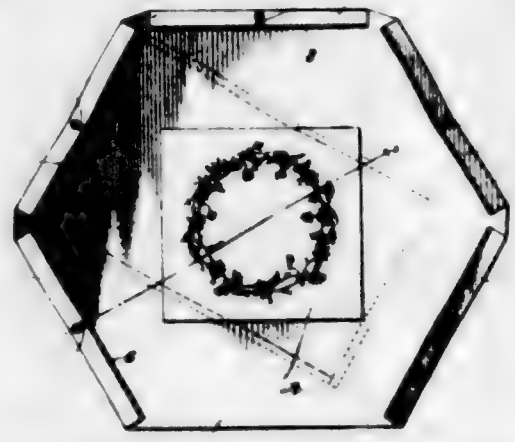
Claim.—1. An envelop having a front face and a flap, and a portion between and integral with said face and flap and doubled to form a strip running along one edge and outside of said envelop, said strip having a backwardly-bent projection free from the body of said envelop by which said strip may be torn off to open said envelop, one of the flaps thereof overlapping and holding said projection.

2. An envelop having a front face and a flap, and a portion between and integral with said face and flap and doubled twice over to form a strip running along one edge and outside of said envelop at one end thereof, said strip having a backwardly-bent projection free from the body of said envelop by which said strip may be torn off to open said envelop, said envelop also having a second flap extending over part of said backwardly-bent projection to hold the same in place.

708,099. MEANS FOR DECORATING FABRICS. ANTOINE VESICH, New York, N. Y. Filed Apr. 6, 1902. Serial No. 101,518. (No model.)

Claim.—1. A means for applying colors to materials comprising a stencil made of a pattern layer having suitable openings or perforations; an open-mesh fabric extending across the pattern layer and the openings therein; and an interposed rubber sheet or layer having certain parts cut out to conform to the pattern openings or perforations of the first-named layer and dissolved by the application of heat and pressure into intimate union with the pattern layer and said fabric layer.

2. A stencil comprising a perforated or cut-out pattern layer, an open-mesh-fabric layer, and an interposed rubber sheet or layer dissolved by the application of heat and pressure and partially filling the pores of the pattern and fabric layers and intimately uniting them throughout their engaging faces, said interposed layer having certain portions thereof cut out or removed and conforming to openings or perforations of the pattern layer.



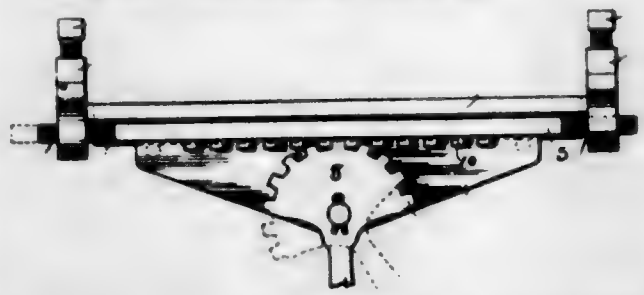
3. A stencil substantially such as described, comprising layers of paper, fabric and an interposed adhesive layer; said paper and adhesive layers being perforated and removed according to the configuration of the pattern and said adhesive layer being dissolved by the application of heat and pressure to the layers, whereby the adhesive layer intimately unites the fabric and paper layers.

4. An apparatus for applying different colors to materials comprising a suitable table having a work-receiving space, a series of different-color stencils arranged to be successively fitted to said space, and a scraper operatively related to the stencils and adapted to be moved across the same, said scraper being effective at a single stroke in applying any one color to the decorative material through one of the stencils.

5. An apparatus for applying colored patterns to materials consisting of a table having a work-receiving space, a group of cut-out different-color stencils arranged to be fitted successively to said space for the pattern-openings to match with one another in applying different colors to the work, another stencil having its pattern or design formed by minute perforations and also arranged to be fitted to the space in matching relation to the patterns applied previously by the cut-out stencils, and a scraper adapted to be drawn across the stencils and effective at a single stroke in applying color therethrough to the work in said space.

6. The combination with a table having a work-receiving space, of a group of stencils attached to said table around said space, and counter-weighted cords attached to the stencils and adapted to maintain them in raised positions with relation to the table.

708,100. SAW-SET. HOLLAND R. VICK, Alliance, Ohio. Filed May 15, 1902. Serial No. 107,429. (No model.)

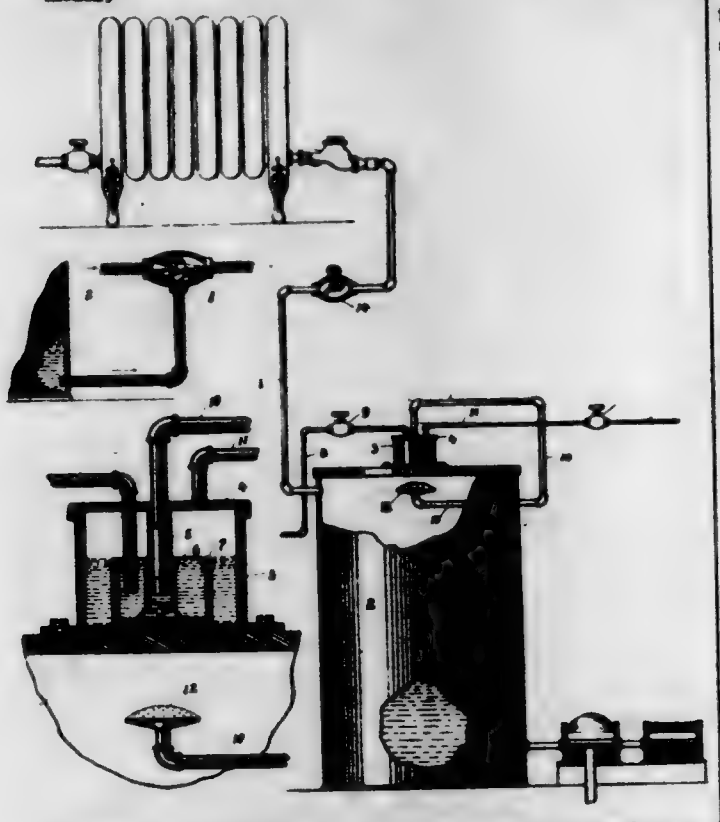


Claim.—1. In a saw-set, the combination of a fixed and movable jaw, said jaws provided with pins or stops and one of the jaws provided with hooked arms, a clamping-bar provided with wedge-shaped ends located opposite the hooked arms, means for imparting longitudinal movement to the clamping-bar, and dies provided with beveled upper edges, said dies located between the jaws, substantially as and for the purpose specified.

2. The combination of jaws one movable and the other fixed, hooked arms extended laterally from the fixed jaw and at the ends of said jaw, said hooked arms provided with set-screws, a clamping-bar carried by the hooked arms and located adjacent to the movable jaw, dies located between the jaws, and means for imparting a reciprocating movement to the clamping-bar, substantially as and for the purpose specified.

3. The combination of jaws provided with downward-extending flanges, one of the jaws movable and the other fixed, a toothed segmental head provided with an operating-handle pivotally attached to the flange of the movable jaw, a clamping-bar provided with teeth adapted to mesh with the teeth of the segmental head, and the clamping-bar provided with wedge-shaped ends, hooked arms carrying the movable jaw and the clamping-bar and dies located between the jaws, substantially as and for the purpose specified.

708,101. VACUUM STEAM-HEATING SYSTEM. JAMES R. WADE, St. Louis, Mo. Filed Jan. 13, 1902. Serial No. 89,483. (No model.)



Claim.—1. In a heating system, a tank or condenser having connection with a steam-circulating system, a trap disconnected from the system having a water-discharge tube leading into said condenser, a pipe for conducting cold water into said trap, a pipe for conveying fluid under pressure thereinto for effecting a subsequent discharge of the water therefrom into the condenser through the water-discharge tube, and means for withdrawing the water, vapor and gases accumulated in said condenser substantially as set forth

2. In a heating system, a tank or condenser having connection with a steam-circulating system, a trap disconnected from the system having a water-discharge tube leading into the condenser, a float or pot normally closing the inner end of said discharge-tube, a water-feed pipe delivering into the pot, a steam-pipe leading to the trap at a point above the surface of the water contained therein, suitable controlling-valves in said pipes, and mechanism for pumping out the contents of the condenser, the parts operating substantially as, and for the purpose set forth.

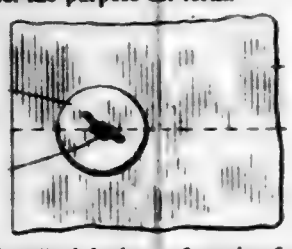
3. In a heating system, a tank or condenser having connection with a steam-circulating system, a trap disconnected from and independent of said circulating system, having a water-discharge tube leading into said condenser, a pipe for conducting cold water into said trap, a pipe for conveying fluid under pressure thereinto for effecting a subsequent discharge of the water therefrom into the condenser through said water-discharge tube, and means for positively withdrawing the contents of the condenser, substantially as set forth.

4. A heating system comprising a tank or condenser having connection with a low-pressure steam-circulating system, a trap mounted on top of the tank, a float in said trap, a water-feed pipe leading into the trap and discharging into said float, a guide-tube depending from the top of the trap, a hollow open stem carried by the float and loosely embracing the guide-tube, a water-discharge tube having one end inserted through the guide-tube and normally closed by the float, the said discharge-tube penetrating the walls of the condenser and discharging thereinto, a steam-pipe communicating with the interior of the trap above the level of the water therein, suitable valves in the pipes, and mechanism adapted to remove the waters, air and gases accumulating in the condenser, the parts operating substantially as, and for the purposes set forth.

5. In a heating system, a tank or condenser having connection with a steam-circulating system, a trap disconnected from the system having a water-discharge tube leading into said condenser, a pipe for conducting cold water into said trap, a pipe for conveying fluid under pressure thereinto for effecting a subsequent discharge of the water therefrom into the condenser through the water-discharge tube, and means for withdrawing the water, accumulated in said condenser and returning the same to the boiler, substantially as set forth.

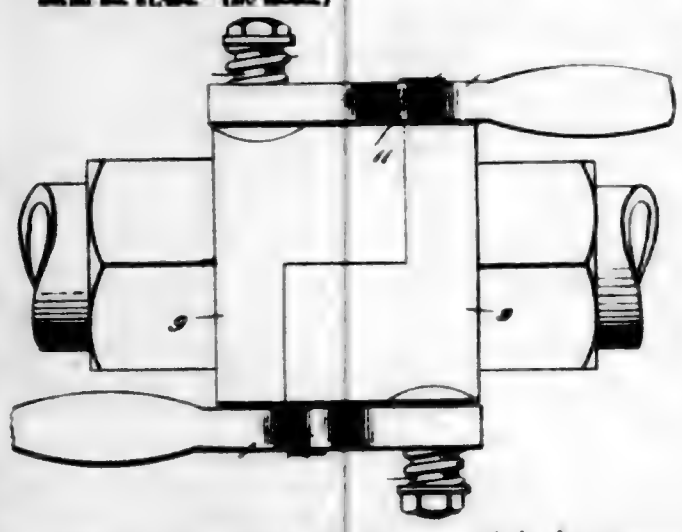
708,102. DEVICE FOR FASTENING LOOSE-LEAF BOOKS. JOHN A. WALDO, Jr., Reading, Mass. Filed June 16, 1902. Serial No. 111,847. (No model.)

Claim.—1. The herein-described device, or fastening for loose-leaf books, consisting of a pair of telescopic tubes, one longitudinally adjustable within the other, each tube having a flange at the outer end, and a fastening-string passing through the tubes and securing them together, substantially as and for the purpose set forth.



2. The herein-described device, or fastening for loose-leaf books, consisting of a pair of telescopic tubes, one longitudinally adjustable within the other, each tube having a flange at the outer end combined with perforated caps or washers, and a tying-string for securing the parts of the fastening device to the loose-leaf book, &c., substantially as and for the purpose set forth.

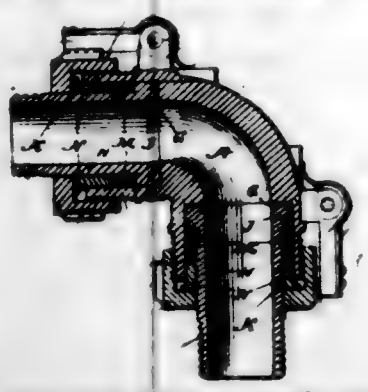
708,108. COUPLING MECHANISM FOR RAILWAY STEAM OR AIR PIPES. HENRY H. WARNER, Tacoma, Wash. Filed Nov. 7, 1901. Serial No. 81,626. (No model.)



Claim.—1. A coupling device for steam and air pipe connections for railway-cars, comprising two members, each of said members having two oppositely-arranged lugs projecting beyond the inner ends of the members and adapted to interlock when the two members have their outer edges together, a cylindrical pin mounted upon one side of the exterior of the members, a pivoted lever mounted upon said pin, a coil-spring surrounding the pin outside the lever, means to hold the spring in place, and an oppositely-arranged pin carried by each member having a flat and a curved side.

2. A coupling device for steam and air pipe connections for railway cars, comprising two members, each of said members having two oppositely-arranged lugs projecting beyond the inner ends of the members, a cylindrical pin mounted upon one side of the interior of the members, a pivoted lever mounted upon said pin, means to yieldingly hold the lever upon the pin, and an oppositely-arranged pin carried by each member to be engaged by the lever of the other member; in combination with pipe connections and means for operating the levers when the cars are a certain distance apart to uncouple the members.

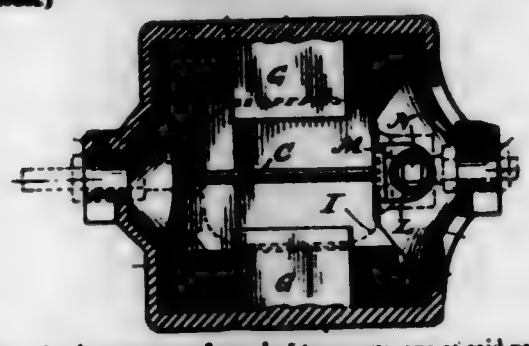
708,104. FLEXIBLE PIPE-JOINT. HENRY H. WARNER, Tacoma, Wash. Filed Nov. 7, 1901. Serial No. 81,627. (No model.)



Claim.—A swivel flexible joint connection for pipes, comprising a pipe provided with a threaded end, a short coupling rotatably mounted in the end of said pipe and having a shouldered inner end, a smooth in-

termediate surface and a threaded outer end, a heat-non-conducting gasket surrounding the smooth surface next to the shouldered end, a hard-rubber gasket having an annular rim surrounding the smooth surface of the coupling and having the rim beyond the threaded end of the pipe, a flanged disk mounted upon the smooth portion and adapted to engage the threaded end of the pipe and compress the gaskets, a series of lugs formed on the extension of the disk, a yoke surrounding the pipes, a pair of lugs carried by the yoke, a detent pivotally mounted between the lugs, and a flat spring connected to the detent and having its free end abutting against the exterior of the pipe to normally hold the detent in engagement with one leg of the flanged disk.

708,105. CASE FOR FAN-MOTORS. HAROLD R. WELLMAN, New York, N. Y., assignor to General Incandescent Arc Light Company of New York, a Corporation. Filed Nov. 16, 1901. Serial No. 82,528. (No model.)



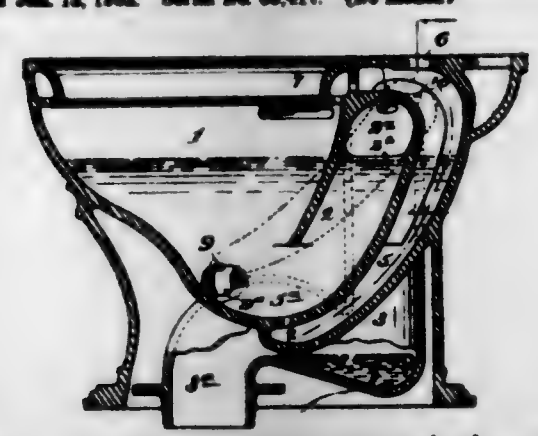
Claim.—1. A motor-case formed of two parts, one of said parts substantially cylindrical in its vertical axis with a horizontal top and bottom and having on one cylindrical surface a circular opening, and the other part formed as a convex disk adapted to be inserted in the circular opening of the other part, and means for securing said parts together.

2. A motor-case formed of two parts, one of said parts substantially cylindrical in outline, with flattened top and bottom, and the other part formed as a convex disk.

3. A motor-case formed of two parts, one of said parts substantially cylindrical in outline, with flattened top and bottom, and the other part formed as a convex disk carrying tubes for the commutator-brushes.

4. A motor-case formed of two parts, one of said parts substantially cylindrical in outline in its vertical axis, with flattened top and bottom, pole-pieces projecting inward from said top and bottom and said part having a circular opening in its cylindrical surface, and the other part formed as a convex disk adapted to be inserted in and secured to said first-named part.

708,106. WATER-CLOSET. FRANK A. WELLS, New York, N. Y. Filed Jan. 13, 1902. Serial No. 89,417. (No model.)

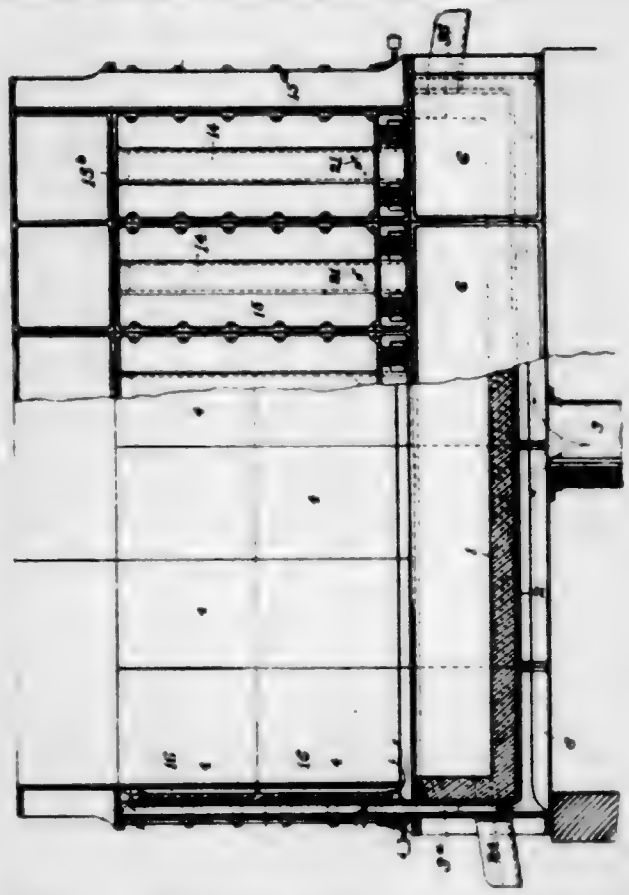


Claim.—1. A water-closet provided with a bowl and up and down communicating passages or legs, a soil-leg communicating with the down-leg, a duct communicating with a jet-opening leading to the bowl, and a duct communicating with the soil-leg below the level of the water in the bowl and with the first-mentioned duct, and also with said passages or legs above the normal level of the water in the bowl, substantially as described.

2. A water-closet provided with a bowl and up and down communicating passages or legs, a soil-leg communicating with the down-leg, a duct communicating with a jet-opening leading to the bowl, the down-leg having an upper jet-opening communicating by a duct with the first-mentioned duct, and a duct communicating above the level of the water in the bowl with the second-mentioned duct and said passages and also with the soil-leg, substantially as described.

3. A water-closet provided with a bowl and up and down communicating passages or legs, the down-leg having a water-pocket and communicating with a soil-leg, a duct communicating with a jet-opening leading to the bowl, a duct communicating with said duct below the normal water-level in the bowl and also communicating with the down-leg above said water-level, and a duct communicating with the soil-leg above said pocket and also communicating with the second-mentioned duct and with said passages above the normal level of the water in the bowl, substantially as described.

708,107. FURNACE. GEORGE WESTINGHOUSE, Pittsburg, Pa. Filed Mar. 25, 1901. Serial No. 52,694. (No model.)



Claim.—1. In a smelting-furnace, an air-jacket consisting of wall-plates having vertical ribs and transverse baffle-plates integral with the inner surface of the plates, the baffle-plates extending across the spaces between adjacent ribs, substantially as described.

2. A smelting-furnace having its outer walls composed of vertical plates having air-passages, an air-inlet and an air-outlet leading to and from said passages, and its inner wall composed of plates having integral heat-radiating ribs, and means for securing the same to the outer wall.

3. A smelting-furnace consisting of a crucible and vertical air-jacketed walls and air inlets and outlets leading to and from the air-jacket, said walls consisting of hollow independently-removable compartments, and heat-radiating ribs integral with the inner walls thereof.

4. In a smelting-furnace, an inclosing wall consisting of wall-plates of iron having heat-radiating ribs integral with one side thereof, and an outer wall to which the wall-plates are independently removably attached.

5. In a smelting-furnace, an air-jacketed wall and air inlets and outlets leading to and from the air-jacket, said wall consisting of an outer supporting structure, and independently-removable sectional wall-plates having heat-radiating ribs integral therewith, substantially as described.

6. A removable section of wall for a furnace, consisting of a wall-plate having vertical and transverse heat-radiating ribs, the transverse ribs being inclined with reference to the wall.

7. A furnace-wall consisting of a series of independently-removable heat-radiating sections, each section comprising a wall-plate having one surface presented to the reduction-chamber of the furnace and having its opposite surface constructed with heat-radiating ribs, and means for detachably securing the wall-plates in the furnace.

8. The combination with the wall-plate 4, of the vertical ribs 16 and 18 projecting from one surface of the wall-plate, and the interposed baffle-plates inclined with reference to the surface of the wall-plate.

9. In a smelting-furnace, the combination of the outer walls, the vertical flues therein, the inner vertical heat-radiating compartment with which said flues communicate at their upper ends, and the tuyeres with which said compartment communicates.

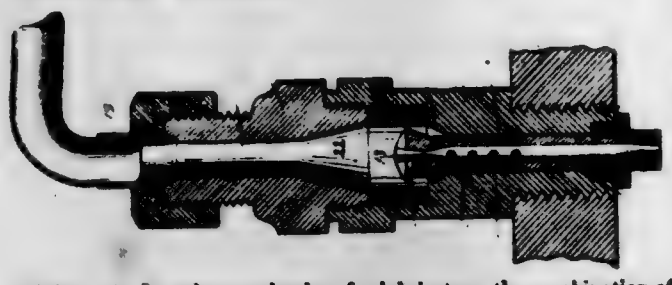
10. In a smelting-furnace, the combination of the outer walls, the vertical flues therein, the inner vertical heat-radiating compartment with which said flues communicate at their upper ends, the tuyeres with which said compartment communicates, and the regulating-dampers in said flues.

11. The combination of the outer walls, constituting the shell of a

furnace, the vertical flues therein, the openings at their lower ends, the air-heating chamber beneath the crucible, the twyers, connections between the heating-chamber and the twyers and connections from the flues to the twyers.

12. The combination with the crucible of a furnace, of the inclosing wall, the vertical flues carried thereby, an air-jacket beneath the crucible communicating with the vertical flues, an air-jacket within the wall of the furnace, connections from the upper ends of the flues with said air-jacket, and openings from the lower end of the jacket into the furnace.

708,108. **VERTICAL-LIFT LUBRICATING-VALVE FOR STEAM-CHESTS.** George Wiesecke, Allegheny, Pa. Filed Apr. 5, 1901. Serial No. 54,507. (No model.)



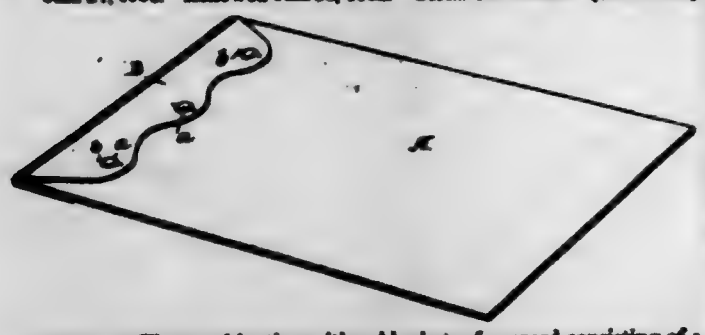
Claim.—1. In valve mechanism for lubricators, the combination of a casing adapted at opposite ends to connect with a steam-chest and a lubricator, a hollow piston-valve movable longitudinally in the casing and provided with permanently-open contracted inlet and outlet orifices and with additional inlet-orifices, separate and distinct from the permanently-open inlet-orifice, said additional orifices being open only when the valve is operated by steam-chest pressure.

2. In valve mechanism for lubricators, the combination of a casing adapted at opposite ends to connect with a steam-chest and a lubricator, a hollow piston-valve movable longitudinally in the casing and provided with permanently-open contracted inlet and outlet orifices, the inlet-orifice being of smaller area than the outlet-orifice, the valve having additional inlet-orifices, separate from the permanently-open contracted inlet-orifice, opened only when the valve is operated by steam-chest pressure.

3. In valve mechanism for lubricators, the combination of a casing adapted at opposite ends to connect with a steam-chest and a lubricator, a hollow piston-valve movable longitudinally in the casing and provided at opposite ends with permanently-open contracted inlet and outlet orifices and with side inlet-orifices separate and distinct from the permanently-open contracted inlet-orifice, the valve-casing being formed with a seat and the lubricator end of the valve with a head complementary with the seat, whereby when the valve is seated the said side inlet-orifices are closed to the ingress of steam and oil.

4. In valve mechanism for lubricators, the combination of a casing adapted at opposite ends to connect with a steam-chest and with a lubricator, a piston-valve operative therein formed with a longitudinal passage-way having its outlet or steam-chest end and its inlet or lubricator end contracted, the intermediate portion of the passage-way being relatively large and provided with lateral inlet-orifices which are open only when the valve is operated by steam-chest pressure.

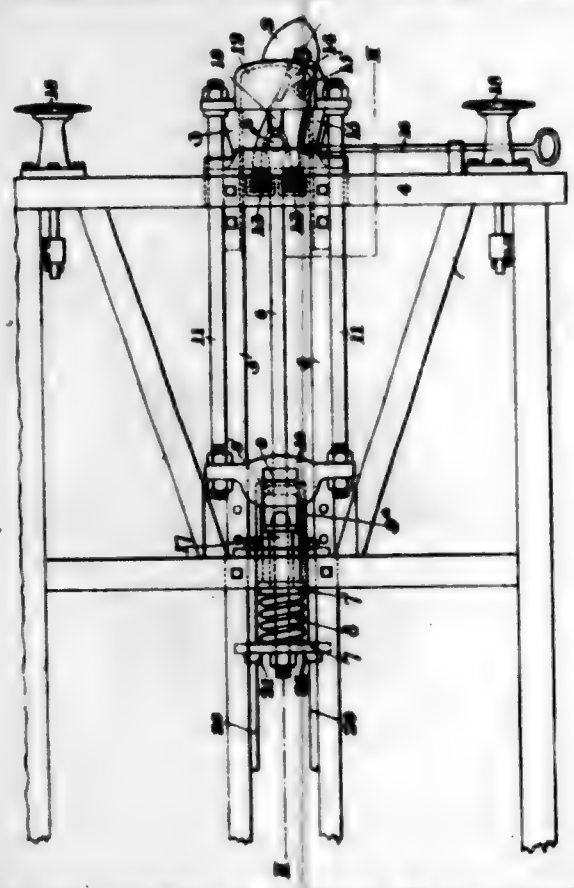
708,109. **BLANKET-GUARD.** Henry H. Williams, Fort Wayne, Ind., assignor of one-fourth to Frank Berger, Fort Wayne, Ind. Filed Jan. 27, 1900. Renewed Jan. 31, 1902. Serial No. 92,072. (No model.)



Claim.—The combination with a blanket, of a guard consisting of a sheet of linen or analogous material folded over one edge of the blanket to prevent contact of the latter with the face of the seer, and means for detachably connecting both folding portions of the guard to the blanket, substantially as set forth.

708,110. **COUPLING FOR RAILWAY-CARRIAGES, &c.** John Williams, Cleveland, Ohio, assignor to the National Malleable Castings Company, Cleveland, Ohio, a Corporation of Ohio. Filed Sept. 26, 1899. Renewed Jan. 28, 1902. Serial No. 92,516. (No model.)

Claim.—1. In a draft-rigging the combination with the draw-head adapted to receive buffing and draft, and a draft-spring, of a lever interposed between these parts and arranged to convert a long buffing motion into a short compression of the spring; substantially as described.



2. In a draft-rigging, the combination with the draw-head adapted to receive buffing and draft, and a draft-spring, of a lever interposed between these parts and arranged to convert a long buffing motion into a short compression of the spring, and a rod interposed between the lever and the buffer parts; substantially as described.

3. In a draft-rigging, the combination with the central buffer or draw-head, and a longitudinally-extending draft-spring, of a lever interposed between these parts and arranged to convert a long buffing motion into a short compression of the spring; substantially as described.

4. The combination of a laterally-swinging draw-head, a movable push-bar against which it has a bearing on both sides of its axial line, a spring, and a lever between the push-bar and the spring; substantially as described.

5. The combination of a laterally-swinging draw-head, having lateral lugs mounted in guide-walls, and a longitudinally-movable spring-backed part against which the lugs bear, and which is adapted to be actuated by lateral swinging of the draw-head; substantially as described.

6. The combination of a draft-spring, a draw-bolt, a lever and a push-bar, and a sleeve 17 on the draw-bolt interposed between the lever and the spring and adapted to be moved by the lever; substantially as described.

7. The combination with a draw-head hook, of an uncoupling-set arm pivoted to the hook, a lever 15 also pivoted to the hook and adapted to engage the side of the set-arm and to hold the same in open position, and an operating-rod; substantially as described.

8. The combination with a central buffer or draw-head, and draft-spring, a bracket at such spring, a lever set in a vertical plane and having its end fitting in a fulcrum-socket in the bracket and bearing against the spring, and means for connecting the spring to the buffer or draw-head; substantially as described.

9. In a draft-rigging, the combination of the draft-spring and buffing device, of a lever interposed between the buffing device and the spring, a sleeve between the spring and the lever, follower-plates for the spring, guide-rods on which the plates are movable, and stops on the guide-rods; substantially as described.

10. The combination of a draft-spring, a draw-head having a direct connection therewith, a buffer, and a lever interposed between the buffer and the draft-spring and adapted to transmit compression of the buffer to compress the spring; substantially as described.

11. The combination of a laterally-swinging draw-head, having lateral lugs mounted in guide-walls, and a longitudinally-movable push-bar against which the lugs have a bearing on both sides of the axial line of the draw-head, a spring, and a lever interposed between the push-bar and the spring; substantially as described.

12. A draw-head and a draft-spring, said draw-head being connected

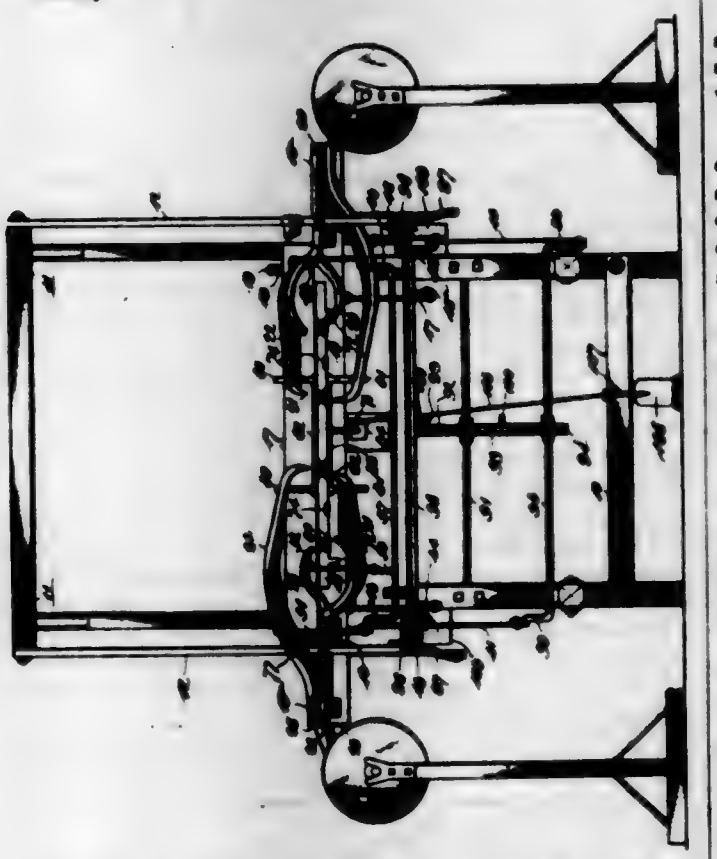
with the draft-spring directly and by an interposed lever and adapted to transmit pulling and buffing force thereto, and also connected therewith in such manner as to transmit to the spring force produced by lateral deflection of the draw-head, whereby the draft-spring is made to perform a triple function of yieldingly resisting the pressure of draft and buffing and lateral deflection; substantially as described.

13. In a draft-rigging, the combination with the central buffer or draw-head, and a spring, of a lever set in a vertical plane and interposed between these parts and arranged to convert a long buffing motion into a short compression of the spring; substantially as described.

14. The combination in a draft-rigging, of a draw-head, a spring, a lever, a push-rod adapted to transmit buffing force to the lever and thence to the spring, and a draw-bolt extending from the draw-head through the lever, said lever being upheld by the draw-bolt; substantially as described.

15. In a draft-rigging the combination with the draw-head adapted to receive buffing and draft, and a draft-spring, of a lever interposed between these parts and arranged to convert a long buffing motion into a short compression of the spring, and a draw-bolt arranged to transmit the force of draft from the draw-head to the spring; substantially as described.

708,111. MACHINE FOR WIRING WOOD SLATS. CHARLES M. ALGER, Hannibal, Mo. Filed Nov. 30, 1901. Serial No. 84,241. (No model.)



Claim.—1. In a machine for wiring wood slats, the combination with wire-carriers, of devices for operating the same to form a shed having a wholly-unobstructed front opening, thereby to permit of the direct edgewise feeding of successive slats.

2. In a machine for wiring wood slats, a slat-hopper located directly in front of the shed and in line with the woven material, and means for feeding slats directly from the hopper to wiring position.

3. In a machine for wiring wood slats, the combination of wire-carriers, devices operating the same to form a shed having an unobstructed front opening, a batten, and slat-feeding devices carried by said batten.

4. In a machine for wiring wood slats, the combination with wire-carriers, of means for moving said carriers above and below the plane of the material being woven, thereby to form a shed having a wholly-unobstructed front opening.

5. In a machine for wiring wood slats, the combination with devices for forming an open-front shed, of a batten, a slat-hopper, and mechanism carried by the batten for removing the slats from the hopper and feeding the same successively to the shed.

6. In a machine for wiring wood slats, the combination with devices for forming an open-front shed, of a slat-hopper, a batten, a slat-support carried thereby, and a slat-engaging hook carried by the batten and adapted to engage with and remove the lowermost slat of the hopper.

7. In a machine for wiring wood slats, the combination with devices for forming an open-front shed, of a slat-hopper, a batten, a slat-support carried thereby, a slat-engaging hook, and a pivoted dog adapted to be operated by the movement of the hook and to elevate said hook into position for engagement with the lowermost slat of the hopper, substantially as specified.

8. In a machine for wiring wood slats, the combination with devices for forming an open-front shed, of a batten, a slat-hopper, a hook carried by the batten and adapted for engagement with the lowermost slat of the hopper, an operating-lever pivoted to the batten and connected to said hook, and a link connecting said lever to the fixed frame of the machine.

9. The combination with devices for forming an open-front shed, of a hopper, a batten, a slat-support carried thereby, a slat-engaging hook, an operating-dog therefor, a slat-engaging finger carried by the batten, and a locking-lever for moving the slat-engaging hook into inoperative position, substantially as specified.

10. In a machine for wiring wood slats, the combination of the wire-carrying fingers arranged in sets and having a pivotal movement in a plane substantially at right angles to the length of the fabric being woven thereby to form a shed having an unobstructed front opening.

11. In a machine for wiring wood slats, the combination of a series of mating sets of wire-carrying fingers having supporting-pivots arranged in a plane substantially at right angles to the length of the fabric being woven and forming after each operation of the fingers an open shed to permit of the edgewise feeding of successive slats.

12. In a machine for wiring wood slats, a batten having a knife-edge adapted for contact with the slats in advance of the change of the shed to produce a seating groove or recess for the wires.

13. In a machine for wiring wood slats, wire-carrying fingers, mechanism for operating the same to change the shed, and pressure-rollers adapted to act on the upper and lower sides of the slat and to force the wires thereinto.

14. In a machine for wiring wood slats, the combination of a series of sets of wire-carrying fingers having an oscillating movement in a plane substantially at right angles to the length of the fabric and adapted to change the shed, a batten-bar, a series of blocks carried by said bar, knives carried by said blocks in alinement with the several sets of fingers and adapted for contact with the slats in advance of the changing of the shed.

15. In a machine for wiring wood slats, the combination with a series of wire-carrying fingers having a pivotal axis in a plane at right angles to the length of the fabric, a series of spring-plates arranged in alinement with the series of sets of fingers, and a batten-bar having a series of batten-blocks also arranged in alinement with the sets of fingers, substantially as specified.

16. In a machine for wiring wood slats, the combination of a pair of wire-carrying fingers having independent pivotal axes, means for simultaneously moving said fingers, and a pair of connected wire-carrying fingers having a pivotal center coincident with one of the first-named fingers and adapted to pass between the fingers of the first pair, substantially as specified.

17. In a machine for wiring wood slats, the combination of the wire-carrying fingers, means for operating the same, and independently-pivoted arms or levers adapted to be engaged by said fingers during the movement of the same in changing the shed, substantially as specified.

18. In a machine for wiring wood slats, the combination of the wire-carrying fingers, means for operating the same, arms or levers pivoted eccentric to the pivotal axes of the fingers and adapted to engage with said fingers during the changing of the shed to prevent vibration of the same, substantially as specified.

19. In a machine for wiring wood slats, the combination of the wire-carrying fingers, means for operating the same, a pair of independently-pivoted arms or levers movable one with each set of fingers toward a central position, said arms or levers acting to resist the movements of the fingers past the central or crossing point, substantially as specified.

20. In a machine for wiring wood slats, the combination with the wire-carrying fingers, of a pair of independently-pivoted levers having notches or seats for the reception of said fingers and adapted to resist the movement of the fingers in changing the shed and to steady and support said fingers during the changing movement, substantially as specified.

21. In a machine for wiring wood slats, the combination with the wire-carrying fingers, of a pair of independently-pivoted levers having notches or seats for the reception of said fingers, and counterbalancing weights or springs operatively connected to said levers, substantially as specified.

22. The combination of the head-block, a bar mounted above the same, springs normally tending to move the bar and block into contact, spring-pressed pressure-rollers arranged in pairs on the block and bar and adapted to receive the successive slats, wire-carrying fingers, means for operating the same, and a movable batten for contact with said slats, substantially as specified.

23. The combination of the head-block, a spring-pressed bar mounted above the same, spring-plates arranged in pairs on the block and bar antifriction-rollers arranged at the outer ends of said plates, supporting-plates carried by the head-block for the reception of the slats, wire-car-

rying fingers, means for operating the same, and a movable batten for forcing said slats, between the constriction-rollers, substantially as specified.

24. In a machine for wiring wood slats, a batten-block having in its forward edge a vertical and a horizontally-disposed groove, and a knife arranged in alinement with said vertical groove.

25. In a machine for wiring wood slats, a batten-block having horizontally-disposed groove and provided upon its upper and lower faces with curved wire-guiding plates, there being at the juncture of said plates an inclined groove for receiving the wire, and a knife carried by the batten-block in alinement with said inclined groove, substantially as specified.

26. The combination of the wire-carrying fingers having pivotal axes in a plane substantially at a right angle to the length of the fabric being woven, a revolvable crank-shaft, means for operating the same, a pair of auxiliary shafts having cranked connections with said crank-shaft, and mechanism operatively connecting the auxiliary shafts to the fingers.

27. The combination of the wire-carrying fingers having pivotal axes in a plane substantially at a right angle to the length of the fabric being woven, a batten, a revolvable crank-shaft operatively connected to the batten, and mechanism for operatively connecting said crank-shaft to the fingers, substantially as specified.

28. The combination of the wire-carrying fingers having pivotal axes in a plane substantially at a right angle to the length of the fabric being woven, a batten, an operating-pawl connected thereto, a sprocket-wheel having pins or teppets adapted for successive engagement by the pawl-bar, a revolvable crank-shaft operatively connected to the sprocket-wheel, and means for connecting said crank-shaft to the wire-carrying fingers, substantially as specified.

29. The combination of the wire-carrying fingers, a batten, pivoted links carried by the frame and connected to the batten, a pawl-bar pivotally connected between the links, a pedal operatively connected to the pawl-bar, a sprocket-wheel having pins or teppets adapted to be engaged by said pawl-bar, a revolvable crank-shaft, a sprocket-wheel thereon, a link belt connecting the two sprocket-wheels, auxiliary shafts having cranked connections with the crank-shaft and rods and cranks for operatively connecting said auxiliary shafts to the wire-carrying fingers, substantially as specified.

30. The combination of the wire-carrying fingers, a batten, mechanism operatively connecting the batten to the wire-carrying fingers, said mechanism including as one of its elements a pair of connecting-bars inclined at an angle to the length of the frame and adapted for engagement with guides on the side of said frame to assist in centering the batten substantially as specified.

31. In a machine for wiring wood slats, the combination with the wire-carrying fingers and devices for operating the same, of a batten adapted to operate directly upon the crossed wires after each change of the shed.

32. In a machine for wiring wood slats, the combination of the wire-carrying fingers arranged in sets, mechanism for operating said fingers to cross the shed, a batten adapted for contact with the slats before the crossing of the shed and for direct contact with the crossed wires after each change of the shed.

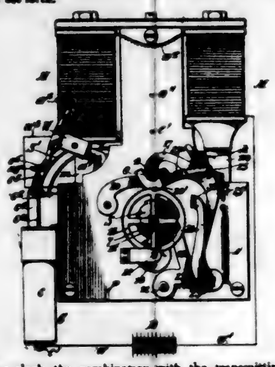
33. In a machine for wiring wood slats, a batten having a knife-edge for contact with the slats in advance of the change of the shed to produce or form in said slats a seating groove or recess for the wires, the knife-edge being adapted for contact with the cross-wires after the change of the shed to force wires into the groove or recess.

34. In a machine for wiring wood slats, the combination of a series of sets of wire-carrying fingers having an oscillating movement in a plane substantially at right angles to the length of the fabric and adapted to change the shed, a batten-bar, a series of blocks carried by said bar, knives carried by said blocks in alinement with the several sets of fingers and adapted for contact with the slats in advance of the changing of the shed and for contact with the crossed wires after the changing of the shed.

708,112. **ELECTRIC CLOCK.** EJALMAR E. ANDERSSON, Stockholm, Sweden. Filed Dec. 1, 1900. Serial No. 38,344. (No model.)

Claim.—1. In a clock, the combination with the arbor carrying the transmitting-gears of the clock-train, a ratchet-wheel and an armature-lever revolvable on said arbor, said lever having one of its arms weighted, a pawl on the other arm thereof in engagement with the aforesaid ratchet-wheel, an electromagnet influencing the lever, and a suitable electric circuit; of a circuit-closer in said circuit operated by the armature-lever to close the electric circuit and rotate the ratchet-wheel during the gravitating movement of the lever, and to again open said circuit when said lever is moved in an opposite direction by the closure of the electric circuit, and means disengaging the pawl from its ratchet-wheel before the armature-lever completes its motion under the action of the weighted arm, for the purpose set forth.

2. In a clock, the combination with the transmitting-gears of the clock-train, a ratchet-wheel, a motor-spring connecting said gears and ratchet-wheel, an armature-lever, an arbor on which said parts are loosely mounted, an electromagnet influencing said lever and a suitable electric circuit one arm of said armature-lever weighted and a pawl on the other arm of said lever engaging the aforesaid ratchet-wheel; of a circuit-closer in said electric circuit operated by the gravitating movement of the armature to close said circuit and rotate the ratchet-wheel and to again open the circuit when said lever is moved in an opposite direction by the previous closure of said circuit and the energizing of the electromagnet, for the purpose set forth.



3. In a clock, the combination with the transmitting-gears of the clock-train, a ratchet-wheel, a motor-spring connecting said gears and ratchet-wheel, an armature-lever, an arbor on which said parts are loosely mounted, an electromagnet influencing said lever and a suitable electric circuit, one arm of said armature-lever weighted and a pawl on the other arm of said lever engaging the aforesaid ratchet-wheel; of a circuit-closer in said electric circuit operated by the gravitating movement of the armature to close said circuit and rotate the ratchet-wheel and to again open the circuit when said lever is moved in an opposite direction by the previous closure of said circuit and the energizing of the electromagnet, and means disengaging the lever-pawl from its ratchet-wheel before said lever completes its gravitating motion, for the purpose set forth.

4. In a clock, the combination with the arbor carrying the hammer-actuating device, a ratchet-wheel secured thereto, an armature-lever loose thereon and having one of its arms weighted, a pawl on its other arm actuating the ratchet-wheel, an electric circuit including an electromagnet influencing the armature-lever, and a circuit-closer acted upon by said lever during its gravitating motion to close the circuit and to open the same again and rotate the ratchet-wheel during its movement in an opposite direction under the influence of the electromagnet energized by the previous closure of said circuit; of a timing mechanism timing the operation of the pawl and operating to disengage the same from its ratchet-wheel in accordance with the number of blows to be struck by the hammer, for the purpose set forth.

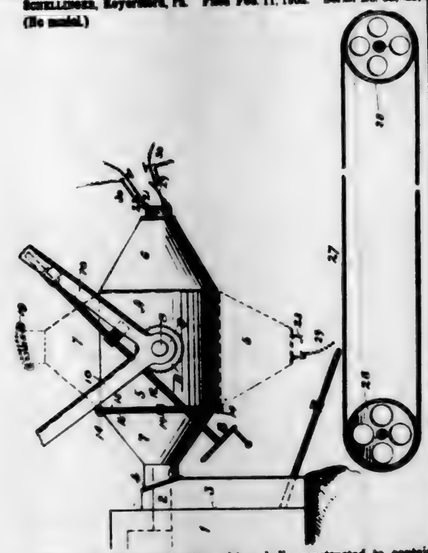
5. In a clock, the combination with the arbor carrying the hammer-actuating device, a ratchet-wheel secured thereto, an armature-lever loose thereon and having one of its arms weighted, a pawl on its other arm actuating the ratchet-wheel, an electric circuit including an electromagnet influencing the armature-lever, and a circuit-closer acted upon by said lever during its gravitating motion to close the circuit and to open the same again and rotate the ratchet-wheel during its movement in an opposite direction under the influence of the electromagnet energized by the previous closure of said circuit; of a let-off cam, a snail, and mechanism controlled thereby and operating to disengage the aforesaid pawl from its ratchet-wheel in accordance with the number of blows to be struck by the hammer, for the purpose set forth.

6. In a clock, the combination with the arbor carrying the hammer-actuating device, transmitting-gearing, a ratchet-wheel 10 and an armature-lever loose on said arbor, a ratchet-wheel 16 fast thereon, a motor-spring connecting ratchet-wheel 10 with the transmitting-gearing, two pawls carried by one arm of the armature-lever whose other arm is weighted, one of said pawls normally engaging ratchet-wheel 10 and the other held normally out of engagement with ratchet-wheel 16, an electric circuit including an electromagnet for aforesaid armature-lever, and a circuit-closer operated by the lever during its gravitating motion to close the electric circuit and to again open the same during its motion in a reverse direction under magnetic influence; of a timing mechanism, means controlled thereby to throw the pawl of ratchet-wheel 10 out of, and the pawl of ratchet-wheel 16 into engagement, and to time the operation of the latter in accordance with the number of blows to be struck by the hammer, for the purpose set forth.

7. The combination with the arbor 4 carrying the pinion 8, hammer-actuating wheel 9 and the ratchet-wheel 10, an electric circuit including an electromagnet and a circuit-closer, an armature-lever loose on said arbor 4 and carrying on one of its arms a pawl in engagement with said ratchet-wheel 10, the other arm of said lever weighted and operating the circuit-closer during its gravitating movement to close the electric circuit and to open the same during its reverse movement under magnetic influence; of a let-off device, a snail, the lever 26 in the path of the let-off device, the arms 24 and 25′ the latter carrying the toothed and flanged segments 25, said arms 24 and 25′ loosely pivoted to an arm 23″ of lever 23, the free end of arm 24 in the path of pinion 8 on aforesaid arbor 4, the arm 20 having its outer end bifurcated and extending under said pinion 8 and forming an abutment for segment 25, and means controlled by arm 20 to move the pawl of ratchet-wheel 16 out of engagement therewith whenever segment 25 is moved out of gear with and by pinion 8, for the purpose set forth.

8. The combination with the oscillating armature-lever, a rock-lever mounted on one of its arms, a pawl rocked by said lever, the arbor 4, the ratchet-wheel 16, the pinion 8 and the hammer-actuating wheel fast on said arbor; of the arm 20 and mechanism substantially such as described controlling the movements of said arm to periodically lift and lower the same, and a connection between said arm and the aforesaid rock-lever, whereby the pawl is moved periodically into and out of engagement with its ratchet to revolve arbor 4, for the purpose set forth.

708,113. **GLASS-LADLE.** BOOTHE H. BALDWIN and ISAAC H. SCHELLINGER, Royersford, Pa. Filed Feb. 11, 1902. Serial No. 93,680. (No model.)



Claim.—1. The combination with a ladle constructed to contain molten glass and having an aperture in the bottom thereof, guides mounted adjacent to said aperture, and a block of refractory material mounted in said guides and having a slot therein to permit the outflow of glass, substantially as described.

2. The combination with a ladle constructed to hold molten glass and having a narrow slot thereon for the outflow of glass, contact-pieces mounted on said ladle and located to be operated by the issuing glass to close a circuit, substantially as described.

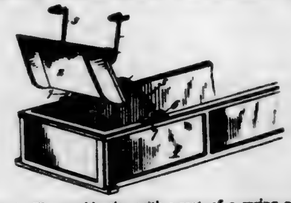
3. The combination with a furnace having an inclined plane face thereon with an aperture therein for the outflow of glass, a ladle mounted to turn about a horizontal axis and provided with an elongated reduced neck having an inclined plane face, said face being located to come in contact with the said inclined face on said furnace when the bore of said neck is in alinement with the said aperture in said furnace, to prevent the entrance of air and limit the movement of the ladle, substantially as described.

708,114. **ROLLER-BRAKE.** LOUIS H. BELL, San Francisco, Cal., assignor to Dusk Brake Company of New York, New York, N. Y. Filed Aug. 13, 1901. Serial No. 72,511. (No model.)

Claim.—1. In a brake for elastic wheel-tires, the combination of a movable supporting member, a plurality of roller-carrying pieces pivotally connected thereto and adapted to swing forward and back of the plane of said member, shafts extending from said pieces and inclining downwardly and outwardly therefrom, rollers loosely mounted on said shafts and friction-blocks secured to the shafts at the backs of said rollers, with means for actuating the supporting member whereby the rollers may be brought into contact with a tire and swung into operative position by the movement of the tire, substantially as set forth.

2. In a brake for elastic wheel-tires, the combination of a movable supporting member, a plurality of roller-carrying pieces pivotally connected thereto and adapted to swing forward and back of the plane of their pivots, rigid shafts inclining downwardly and outwardly from said pieces and having loose rollers and fixed friction-blocks thereon, means to limit the swinging movement of the carrying-pieces and means for actuating the movable supporting member whereby the rollers may be brought into contact with a tire, substantially as and for the purpose set forth.

708,115. **SEAT-SPRING FOR VEHICLES.** GEORGE E. BLAIER, Coshocton, Ohio. Filed Jan. 20, 1902. Serial No. 91,574. (No model.)



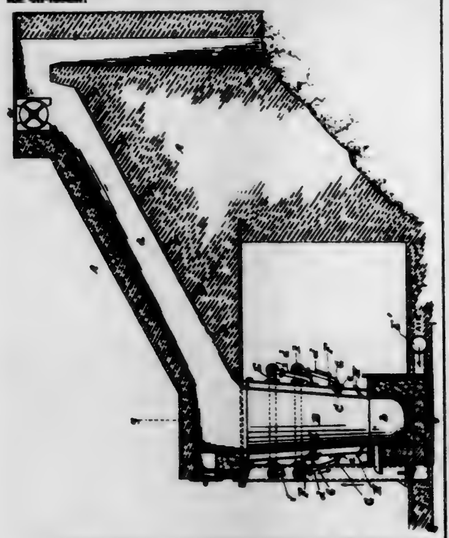
Claim.—1. The combination with a seat, of a spring consisting of two coils terminating in arms adapted to engage the upper edge of the wagon-box, and a second set of arms leading from said coils and lying in the same horizontal plane as the upper portions of the coils and formed with a loop, the upper surface of said coils, the last-named arms and the loop contacting with and supporting said seat, and means for adjustably connecting said loop to said seat, said means comprising a clasp surrounding the sides of the loop and having its ends embedded in the lower side of the seat, and a screw passed through said clasp between the sides of the loop and into said seat, substantially as set forth.

2. The combination with a wagon-box and a seat, of a spring consisting of two coils terminating in arms, one of which is pivotally connected to the upper edge of the side of the wagon-box, and the other of which has a loose hook engagement therewith, said springs being provided with a second set of arms lying in a horizontal plane and parallel with the upper portions of the coils and terminating in a loop, and means for adjustably connecting said loop to said seat, said means comprising a clasp surrounding the sides of the loop and having its ends embedded in the lower side of the seat, and a screw passed through said clasp between the sides of the loop and into the seat, substantially as set forth.

708,116. **IRON BLAST-FURNACE.** MARTIN P. ROSS, San Francisco, Cal., assignor to Hydro-Carbon Smelting Co., New York, N. Y., a Corporation of West Virginia. Filed July 13, 1901. Serial No. 66,733. (No model.)

Claim.—1. In a blast-furnace, a water-jacketed fire-chamber, a tuyer extending therethrough, an oil-feeder inserted through the water-jacket of said chamber and communicating with the interior of the tuyer at a point intermediate of its ends, and an air-feeder projecting into the tuyer, and adapted to discharge at a point adjacent to the point of discharge from the oil-feeder.

2. In a blast-furnace, a water-jacketed fire-chamber, a tuyer extending therethrough, an inclined oil-feeder projecting through the outer wall of said chamber and into the upper portion of the tuyer at a point intermediate of its ends, and an air-feeder projecting into the said tuyer and arranged to discharge at a point adjacent to the point of discharge from the oil-feeder.



3. In a blast-furnace, a fire-chamber, a tuyer extending through the wall thereof, an oil-feeder projecting through said wall at a point above the tuyer and arranged to discharge therein, and an air-feeder arranged longitudinally of the tuyer and projecting therein from the outer end thereof, said feeder being arranged to discharge at a point adjacent to and below the point of discharge from the oil-feeder.

4. In a blast-furnace having an air-blast tuyer extending through the wall thereof, an oil-feeder inserted through the wall of said tuyer, a cap-plate *c* fitting over the outer end of the tuyer and an air-feeder projecting into the tuyer through said cap-plate and adapted to discharge at a point adjacent the discharge from the feeder at an angle thereto, substantially as described.

5. In a blast-furnace having an air-blast tuyer extending through the wall thereof, an oil-feeder inserted through the wall of said tuyer, a relatively flat cap-plate fitting over the outer end of the tuyer and an air-feeder projecting into the tuyer through said cap-plate and adapted to discharge at a point adjacent the discharge from the feeder at an angle thereto, and a removable auxiliary cap covering an opening in the cap-plate in alinement with the tuyer, substantially as described.

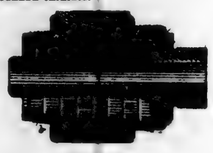
6. In a blast-furnace, a water-jacketed fire-chamber, air-blast tuyers C extending through and supported at opposite alined points in the opposite walls of said chamber, oil-feeders passing through the water-jacket of said chamber and leading into said tuyers and valved feeder-pipes H below said tuyers C also extending through and supported at alined points in the opposite walls of the water-jacket, substantially as described.

7. In a blast-furnace, a water-jacketed fire-chamber, a tuyer extending therethrough, and oil and air feeders associated with said tuyer and projecting therein and arranged to discharge into the fire-chamber, said oil-feeder passing through the water-jacket of said chamber, substantially as described.

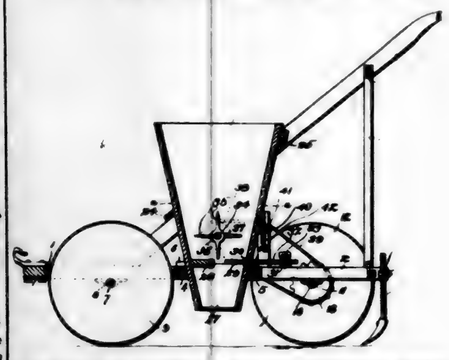
8. In a blast-furnace, a water-jacketed fire-chamber, an air-blast tuyer C extending through and supported in the opposite walls of said chamber, an oil-feeder passing through the water-jacket of said chamber and leading into said tuyer, and a second feeder-pipe H below said tuyer and also extending through the water-jacket of the fire-chamber and arranged to discharge into said fire-chamber, substantially as described.

708,117. RETAINER FOR HOSE-COUPLINGS. WILLIAM F. BOWERS, San Francisco, Cal. Filed Apr. 3, 1902. Serial No. 101,520. (No model.)

Claim.—In a device of the character described, the combination with a coupling provided with a peripherally-grooved collar and a tubular extension adapted to fit into the end of a hose, of a tapering externally-screw-threaded sectional thimble which surrounds the end of the hose fitted over the tubular extension of the coupling, the outer end of the thimble-sections being inwardly flanged to engage with the peripheral groove of the coupling-collar, and a tightening-nut which screws onto the tapering screw-threaded thimble.



708,118. FERTILIZER-DISTRIBUTER. ELIAS L. BRAXTON, Pactolus, N. C. Filed Nov. 20, 1901. Serial No. 83,758. (No model.)



Claim.—1. In a fertilizer-distributer, the combination of a wheeled frame having cross-bars forming an opening therein, a downwardly-tapered hopper having its lower portion inserted between said cross-bars and bearing against the same, handles attached to the frame and disposed on opposite sides of the hopper, cross-bars connecting said handles and disposed on and bearing against the front and rear sides of the upper portion of the hopper, a cut-off slide-plate operating in an opening in one side of the hopper, extending outwardly therefrom and having a longitudinal slot, a support fixed on the frame for the outer end of said slide, and a clamping-screw in said support and operating in said slot, substantially as described.

2. In a fertilizer-distributer, the combination of a frame, a centrally-disposed supporting-wheel at the front end thereof, a shaft journaled in bearings near the rear end of the frame, supporting-wheels on said shaft on opposite sides of the frame, a sprocket-wheel on said shaft, at one side of the frame, a hopper supported on the frame, a stirring-shaft journaled in the hopper, a sprocket-wheel on the stirring-shaft at one side of the hopper, a sprocket-chain connecting said sprocket-wheels, and a feeder on one side of the frame, in advance of one of the side wheels and extending in advance of and laterally beyond the sprocket-wheel on the stirring-shaft, substantially as described.

708,119. SIGHT FOR FIREARMS. JAMES T. BRAYTON, Chicago Ill. Filed May 13, 1901. Serial No. 60,796. (No model.)

Claim.—1. The combination with the front sight and a double-concave-lens sight at the breech, of a plate mounted on the barrel, a bridge adjustably connected to the said plate, a frame hinged to said bridge and a double-convex lens held in said frame, substantially as described.

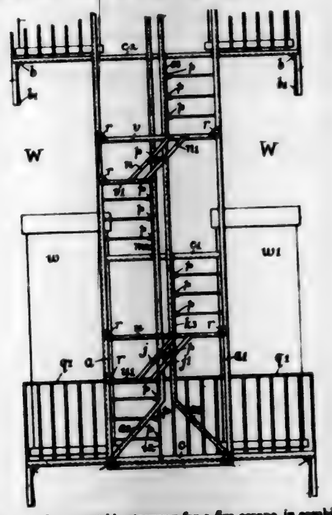
2. A plate mounted upon the barrel, a bridge mounted to slide along said plate, detents for locking the said bridge to said plate and a double-convex lens mounted on said bridge, substantially as described.

3. The combination with the front sight and a double-convex-lens sight at the breech, of a bridge adjustably mounted on the barrel, a frame hinged to said bridge and a double-convex lens held in said frame.

4. The combination with the front sight and a double-convex-lens sight at the breech, of a bridge adjustably mounted on the barrel, a frame hinged to said bridge, said frame being provided with spring-clamps for holding a double-convex lens, substantially as described.

5. In a sight for firearms a bridge adjustably mounted on the barrel, a tilting frame hinged to said bridge, a double-convex lens held by said tilting frame and an open sight adjacent to said tilting frame, substantially as described.

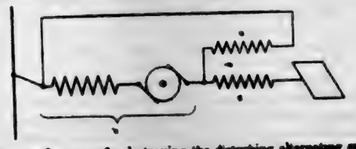
708,120. FIRE-ESCAPE. JAMES H. BRASELL, Rochester, N. Y. Filed Dec. 2, 1901. Serial No. 84,372. (No model.)



Claim.—1. In an outside stairway for a fire-escape, in combination with the four vertical members constituting the outer and inner corners around which the stairway is built, horizontal pieces connecting the outside vertical members together and horizontal members also connecting such outside vertical members with the building, such last-named horizontal members constituting supports for the several platforms or balconies next to the building, flights of steps leading from the platforms next to the building to the platforms or landings supported by such vertical members and carried around such inner vertical members and within such outer vertical members, tie-rods extending obliquely from the inner ends of one pair to the outer ends of a lower pair of such horizontal members connected with the outside vertical members, all of such vertical members supported from and connected with such horizontal members.

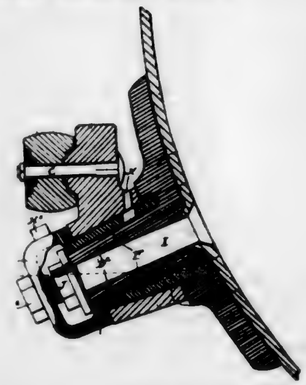
2. In an outside stairway for a fire-escape, in combination with the four vertical members constituting the outer and inner corners around which the stairway is built, horizontal pieces connecting the outside vertical members together and horizontal members also connecting such outside vertical members with the building, such last-named horizontal members constituting supports for the several platforms or balconies next to the building, flights of steps leading from the platforms next to the building to the platforms or landings supported by such vertical members and carried around such inner vertical members and within such outer vertical members, and tie-rods extending obliquely downward and outward from the building and supporting the outer vertical members and the horizontal members by connections therewith at or near their junction, all of such vertical members supported from and connected with such horizontal members.

708,121. DEVICE FOR OVERCOMING ALTERNATING CURRENTS IN DIRECT-CURRENT CIRCUITS. REINHARD BRODHUN, Berlin, Germany. Filed Mar. 20, 1902. Serial No. 100,342. (No model.)



Claim.—In means for destroying the disturbing alternating current in the conductors of electric railroads worked with direct current, a transformer the primary winding of which is connected in the series circuit, and the secondary in a short-circuit to the motor, in such manner that on the common path through the motor, the alternating current generated by the latter flows in opposite direction to the current produced in the secondary winding, for the purpose of removing the former, substantially as described.

708,122. PLOW. JUDSON BUCHANAN, Chattanooga, Tenn., assignor to Chattanooga Plow Co., a Corporation of Tennessee. Filed Jan. 13, 1902. Serial No. 89,433. (No model.)



Claim.—1. In a rotary moldboard-plow, the combination with a plow-beam, of a hanger, a bearing comprising a tubular bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bushing, means for securing said journal in said bushing, and a cup-shaped cap extending over the lower end of said journal and secured to said bushing by a dust and oil tight joint, substantially as described.

2. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bushing, means for securing said journal in said bushing, and a cup-shaped cap extending over the lower end of said journal and threaded to said bushing, substantially as described.

3. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bushing, means for securing said journal in said bushing, and a cup-shaped cap extending over the lower end of said journal and threaded around said bushing and abutting against said hanger, substantially as described.

4. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bushing, and a nut for securing said journal in said bushing, and a cup-shaped cap extending over the lower end of said journal and threaded around said bushing, substantially as described.

5. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bushing, a nut for securing said journal in said bushing, and a cup-shaped cap extending over the lower end of said journal and threaded around said bushing and abutting against said hanger, substantially as described

6. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard a journal rigid upon and extending from the moldboard through said bushing, a bolt extending through said moldboard and said journal, a nut applied to said bolt, and a cup-shaped cap extending over the lower end of said journal and secured to said bushing by a dust and oil tight joint, substantially as described.

7. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bush-

ing, a bolt extending through said moldboard and journal, a nut applied to said bolt, and a cup-shaped cap extending over the lower end of said journal and threaded to said bushing, substantially as described.

9. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular bushing located within said hanger and inclined downward from said moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bushing, a bolt extending through said moldboard and journal, a nut applied to said bolt, and a cup-shaped cap extending over the lower end of said journal and threaded around said bushing and abutting against said hanger, substantially as described.

9. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular, tapering bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bushing, means for securing said journal in said bushing, and a cup-shaped cap extending over the lower end of said journal and threaded to said bushing, substantially as described.

10. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular, tapering bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bushing, means for securing said journal in said bushing, and a cup-shaped cap extending over the lower end of said journal and threaded around said bushing and abutting against said hanger, substantially as described.

11. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular, flanged bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bushing, means for securing said journal in said bushing, and a cup-shaped cap extending over the lower end of said journal and secured to said bushing by a dust and oil tight joint, substantially as described.

12. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular, flanged bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bushing, means for securing said journal in said bushing, and a cup-shaped cap extending over the lower end of said journal and threaded around said bushing and abutting against said hanger, substantially as described.

13. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular, flanged bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bushing, a nut for securing said journal in said bushing, and a cup-shaped cap extending over the lower end of said journal and threaded around said bushing, substantially as described.

14. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular, flanged bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal rigid upon and extending from the moldboard through said bushing, a bolt extending through said moldboard and said journal, and a cup-shaped cap extending over the lower end of said journal and secured to said bushing by a dust and oil tight joint, substantially as described.

15. In a rotary moldboard-plow, the combination with the plow-beam, of a hanger, a bearing comprising a tubular, flanged bushing located within said hanger and inclined downward from the moldboard, a rotary moldboard, a journal extending from the moldboard through said bushing, a bolt extending through the moldboard and journal, a nut applied to said bolt, and a cup-shaped cap extending over the lower end of said journal and threaded around said bushing and abutting against said hanger, substantially as described.

16. In a rotary moldboard-plow, the combination with a beam and a hanger formed integral with said beam, of a bearing comprising a tubular bushing located within said hanger and inclined downward, and a cup-shaped cap secured over the lower end of said bushing by a dust and oil tight joint, substantially as described.

17. In a rotary moldboard-plow, the combination with a beam and a hanger formed integral with said beam, of a bearing comprising a tubular bushing located within said hanger and inclined downward, and a cup-shaped cap threaded to the lower end of said bushing, substantially as described.

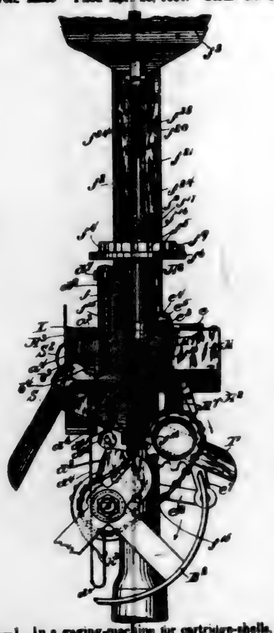
18. In a rotary moldboard-plow, the combination with a beam and a hanger formed integral with said beam, of a bearing comprising a tubular bushing located within said hanger and inclined downward, and a cup-shaped cap threaded around the lower end of said bushing and abutting against said hanger, substantially as described.

19. In a rotary moldboard-plow, the combination with a beam and a hanger formed integral with said beam, of a bearing comprising a tapering, tubular bushing located within said hanger and inclined downward, and a cup-shaped cap secured over the lower end of said bushing by a dust and oil tight joint, substantially as described.

20. In a rotary moldboard-plow, the combination with a beam and a hanger formed integral with said beam, of a bearing comprising a flanged, tubular bushing located within said hanger and inclined downward, and a cup-shaped cap secured over the lower end of said bushing by a dust and oil tight joint, substantially as described.

21. In a rotary moldboard-plow, the combination with a beam and a hanger formed integral with said beam, of a bearing comprising a flanged, tubular bushing located within said hanger and inclined downward, and a cup-shaped cap threaded around the lower end of said bushing and abutting against said hanger, substantially as described.

708,128. CARTRIDGE-SHELL-GAGING MACHINE. PAUL BUTLER, Lowell, Mass. Filed Apr. 28, 1897. Serial No. 633,902. (No model.)



Claim.—1. In a gaging-machine for cartridge-shells, the combination with a gage-passage adapted to admit articles of a predetermined size or smaller but to exclude articles of a larger size, of a succeeding passage or passages in alinement with said gage-passage each smaller than and independent of the one preceding it, means for positively moving an article toward said series of passages until stopped by one of them, and ejecting devices for ejecting an article standing in any of the positions determined by the gage-passages, substantially as described.

2. The combination with a pair of gage-passages, of a support longitudinally movable therein, a feeler adapted to engage a shell stopped at the mouth of either passage, ejecting devices adapted to operate on said shell when released by said feeler, and connecting mechanism whereby said parts are caused to coöperate, substantially as described.

3. In a gaging-machine for cartridge-shells, the combination with a gage-passage, of a support longitudinally movable through said passage a feeler movable with said support and adapted to engage a shell which will not pass through said passage, an ejecting device for said shell adapted to operate when the shell is disengaged by the said feeler, and connecting mechanism whereby said parts are caused to coöperate, substantially as described.

4. The combination with the gage-passages and means for presenting a shell thereto, of the means for controlling the movement of the shell with relation to said passages consisting of a supporting-pedestal for the shell movable through said passages, and a feeler movable with said pedestal to engage a shell which will not pass through said passages or either of them, substantially as described.

5. The combination with a gage-passage, of a reciprocating carriage adapted to present a shell thereto, a pedestal to receive and support a shell thus presented, means for moving said pedestal to permit the shell supported thereon to enter said passage, a feeler movable with said pedestal to engage a shell which is too large to enter said passage, and a portion of the carriage adapted to yieldingly engage a shell during the movement of said carriage in the opposite direction, substantially as described.

6. The reciprocating carriage *c* provided with the jaws c^2 and the ejector-spring c^{10}, combined with the gage-passage *a* and the feeler d^3, as and for the purpose described.

7. The combination with the different-sized gage-passages in alinement with each other, of the reciprocating support adapted, when free, to move through said passages away from the openings thereof to which a shell is presented, the feeler movable with said support, and means for positively actuating said support toward said openings, substantially as described.

8. The combination with a gage-passage and means for presenting a shell thereto, of a second gage-passage in line therewith, a support or pedestal movable through said passages, a feeler adapted to engage a shell stopped by either passage, a spring-operated ejecting device for shells stopped by the second passage adapted to be set by said pedestal in its movement in one direction, and means for maintaining it set during the movement thereof in the opposite direction, substantially as described.

9. The combination with a gage-passage and means for presenting a shell thereto, of a second gage-passage in line therewith, a support or pedestal movable through said passages, a feeler adapted to engage a shell stopped by either passage, a spring-operated ejecting device for shells stopped by the second passage adapted to be set by said pedestal in its movement in one direction, an engaging member adapted to maintain said ejector set until engaged by a shell stopped by the passage and held by the feeler, and means for disengaging said member after the shell is so held, substantially as described.

10. The combination with the gage-passage and the reciprocating carriage for the shells, of the movable support and feeler, an ejecting device comprising a spring-actuated plunger adapted to be set by said movable support, a retaining device for maintaining said plunger set, and an operating-cam for said retaining device coöperating with the reciprocating carriage, substantially as and for the purpose described.

11. The combination of the spring-actuated plunger *g* having the inclined surface g^2; with the pedestal *d*; the retaining device g^3 and means for operating the same; and the feeler d^3, substantially as and for the purpose described.

12. The combination with a reciprocating carriage adapted to receive a shell and present it to a suitable gage-passage, of a movable support for the shell, a cam for positively moving said support to a position to receive a shell presented by the carriage, means for yieldingly producing the return movement of said support, a feeler movable with said support, and actuating mechanism for said carriage and cam whereby the downward movement of the support and feeler takes place substantially when the carriage is in position to present the shell to the gage-passage, substantially as described.

13. In a machine for operating on cartridge-shells, the combination with a feed-chute adapted to receive said articles from a suitable hopper, of a traveling receiver for said articles; cams in the path of a shell carried by said receiver for overturning and righting said shell if presented to said receiver wrong end up while said shell is still in the receiver, and an opening in the path of the shells carried by the said receiver, through which opening said shells are fed to the machine, substantially as described.

14. In a machine for operating on cartridge-shells, the combination with a feed-chute adapted to receive said articles from a suitable hopper, of a traveling receiver for said articles, a cam adapted to engage the mouth of a shell traveling in said receiver and draw it aside until the shell falls on its side without leaving the receiver; and means for righting said fallen shell in the receiver, substantially as described.

15. In a machine for operating on cartridge-shells, the combination with a feed-chute adapted to receive said articles from a suitable hopper, of a traveling receiver for said articles, a cam adapted to engage the mouth of a shell traveling in said receiver and draw it aside until the shell falls on its side in the receiver; an inclined surface beyond said cam adapted to engage the mouth end of a shell during the onward movement of the traveling receiver and lift said end until the shell stands on its flanged end in the receiver, and an opening in the path of shells carried by the traveling receiver through which all of the shells in the receiver are fed to the machine, substantially as described.

16. The combination with the chute f^3, of the support f^6 provided with an opening f^7, the traveling receiver f^5 having recesses f^8, the cam f^9, and the inclined surface f^{10} adjacent to the said receiver and in the path of an article carried thereby, substantially as herein shown and for the purpose described.

17. The combination with a feed-chute adapted to contain a column of shells endwise, with a support for the shells below said chute, means for moving said shells along the surface of said support, a cam in the path of shells thus moved, arranged to engage the mouth of a shell but not the flanged end thereof and inclined to the direction of travel of the shell, whereby the mouth of the shell is drawn from under the center of gravity to tip the shell upon its side, an inclined righting-surface so positioned with relation to the receiver as to be in the path of the shell thus tipped; and an opening in the said support to which the shells are finally carried, substantially as described.

18. The combination with a feed-chute adapted to contain a column of shells endwise, of a traveling shell-receiver below said chute having recesses each adapted to receive and carry along a shell dropped therefrom, a lateral opening in said chute of sufficient size to permit a shell to pass out laterally in the direction of movement of the traveling receiver, and a normally closed gate for said opening arranged to open in response to pressure, whereby a shell caught by the receiver before it has fully emerged from the chute is permitted to escape therefrom without detriment, substantially as described.

19. In a machine for operating on cartridge-shells, the combination with the feed-chute adapted to receive said articles from a suitable hopper, of a traveling receiver for said articles adapted to receive the articles endwise from the feed-chute, a support for the articles along which they are propelled by the receiver, and a cam adapted to engage the end of an article as it is propelled by said receiver and deflect the same until the said article falls from its end upon its side, substantially as described.

20. In a machine for operating on cartridge-shells, a rotating feed-disk having radial recesses, means for presenting articles to said recesses either end uppermost, a support for the articles along which they are carried by said disk, and a cam stationary with relation to said disk and adapted to engage and deflect one end of an article traveling along the support but not the other whereby the articles will remain on end upon the support or be tipped over sidewise upon the support according to the position in which they were originally presented, substantially as described.

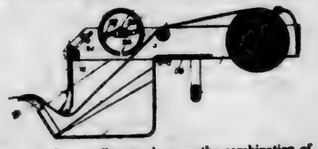
21. In a machine for operating on cartridge-shells or other articles the opposite ends of which differ in shape, the combination with a traveling carrier adapted to receive one of such articles in a substantially vertical position, of a support for said article below said carrier, and a cam formed on said support and so shaped and arranged as to engage and deflect an article traveling along the support on one end but not an article traveling along the support on the other end.

22. The combination with a disk having radially-arranged shell-receiving recesses; of means for feeding shells thereto either end up; and cams so arranged with relation to said disk as to coöperate therewith in rearranging the shells after they have been fed thereto to secure a uniform end arrangement thereof in said disk.

23. In a machine for operating on articles the longitudinal dimension of which is greater than the lateral dimension, the combination with a traveling receiver adapted to receive one or more of such articles vertically positioned, of a support below the said receiver for said article, a cam or deflecting surface so arranged with relation to said receiver as to engage an article propelled thereby at a point near one end thereof, and means for substantially preventing a lateral movement of the other end of the article in the same direction while it is engaged by the cam, whereby said article is tipped from a vertical to a horizontal position upon said support, substantially as described.

24. In a machine for operating on articles the longitudinal dimension of which is greater than the lateral dimension, the combination with a traveling receiver having laterally-open recesses along its periphery each adapted to contain and forward one of such articles, of means for tipping said articles from a vertical to a horizontal position in the travel of the receiver, and means for preventing the articles thus tipped from escaping endwise from the recesses, substantially as described.

708,124. WALL-PAPER HANGER. JOSEPH P. CAMPON, Elma, Iowa. Filed Jan. 7, 1902. Serial No. 88,744. (No model.)



Claim.—1. In a wall-paper hanger, the combination of a frame, a paper-bearing roller mounted in said frame near the front end thereof, means for controlling the paper on said roller, a paste-spreading brush pivotally mounted in the rear end of said frame, shoulders on the inside

of the sides of the frame in front of said paste-spreading brush, a brush-bearing shaft mounted in the said shoulders, a hollow-cylinder paste-tank having a longitudinal slot therein mounted on said shaft and outside of the brush portions thereof, a roller mounted on the sides of the frame between the paper-bearing roller and the cylindrical paste-tank, connecting-pieces between the sides of the frame, a handle attached to the under surface of the said connecting-piece, a drip-cup detachably connected with said connecting-piece and extended under the roller paste-tank, a brush-bearing frame pivotally and adjustably attached to the rear end of said frame, for the purposes stated.

2. In a wall-paper hanger, the combination of a frame, a paper-bearing roller mounted in said frame, means for controlling the paper on said roller parallel to the front end thereof, a paste-spreading brush pivotally mounted in the rear ends of said frame, means for limiting the pivotal movement of said paste-spreading brush, shoulders on the inside of the sides of the frame in front of said paste-spreading brush, a hinged top portion to said shoulders, means for holding said hinged portion firmly to the shaft, a brush-bearing shaft mounted in said shoulders, a cylinder paste-tank having a longitudinal slot therein mounted on said shaft and outside of the brush portion thereof, a roller mounted in the side of said frame between the paper-bearing roller and the cylinder paste-tank, a connecting-piece between the sides and attached to them at its end portion, a handle firmly attached to the under surface of the said connecting-piece a drip-cup detachably connected with said connecting-piece to hang near the cylinder paste-tank, a brush-bearing frame pivotally and adjustably attached to the rear end of said frame comprising two side pieces, and a brush portion between said side pieces, for the purposes stated.

3. In a wall-paper hanger, the combination of a frame, a paper-bearing roller detachably mounted in said frame near the front end thereof, a leaf-spring attached at one end to the front end piece of said frame and extended inwardly, a paste-spreading brush pivotally mounted in the rear ends of said frame, means for limiting the movement of said paste-spreading brush, shoulders on the inside of the sides of the frame in front of said paste-spreading brush, a brush-bearing shaft detachably mounted in said shoulders, means for holding said shaft in said shoulders, a cylinder paste-tank having a longitudinal slot therein and having covers on each end thereof, shoulders on the inner surface of the cylinder portion of said covers, an end portion in said cover deflected inwardly, said paste-tank being mounted on said shaft and outside of the brush portion thereof, a roller rotatably mounted in the sides of the frame near the paper-bearing roller and the cylinder paste-tank, a connecting-piece between the sides and firmly attached to them at its end portions, a handle attached to the under surface of said connecting-piece, means for holding said drip-cup firmly in place beneath the cylinder paste-tank, a brush-bearing frame pivotally attached to the rear ends and on the opposite sides of the said frame, means for limiting the pivotal movement of said brush-bearing frame for the purposes stated.

708,125. COATING-MACHINE. GABRIEL CARLSON, Springfield, Mass., assignor to Confectioners' Machinery and Manufacturing Company, Springfield, Mass. Filed May 9, 1901. Serial No. 59,632. (No model.)

Claim.—1. In a coating-machine, an endless series of center carriers or baskets; means for moving the carriers over a coating-material tank; means for applying coating material to the contents of the carriers, a series of plucks and means for automatically removing the coated goods from the carriers and depositing the same upon the plucks.

2. In a coating-machine, the combination with the coating-material tank, of a vertical reciprocatable pan adapted and arranged to periodically raise coating material from the tank, and means for reciprocating the same.

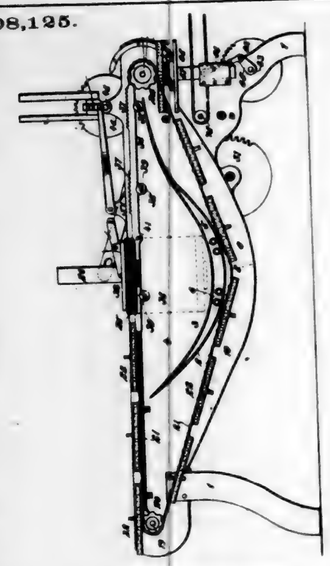
3. In a coating-machine, an endless series of center carriers or baskets; means for moving the carriers over a coating-material tank; a vertically-reciprocatable pan for applying coating material to the contents of the carrier, and means for jarring or shaking the carriers at intervals.

4. In a coating-machine, an endless series of center carriers or baskets; a coating-material tank; means for passing the center carriers over the coating-tank and applying a coating to the contents of the carriers by means of a vertically-reciprocatable pan, and means for automatically removing excess of coating material from the contents of the carriers, substantially as shown and described.

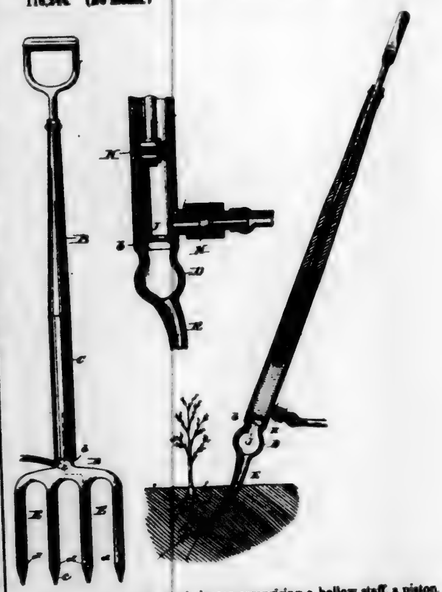
5. In a coating-machine, an endless series of center carriers or baskets; means for moving the carriers over a coating-material tank; means for applying a coating to the contents of the carriers; means for jarring the carriers and their contents, and means for removing the coated goods, substantially as shown and described.

6. The combination with a series of center carriers or baskets and means for moving the same, of the horizontal, vertically-adjustable, reciprocatable rack-bars, and means for reciprocating said bars.

708,125.



708,126. PORTABLE IRRIGATOR. JOHN F. CHASE, St. Petersburg, Fla. Filed June 11, 1901. Renewed July 19, 1902. Serial No. 116,344. (No model.)

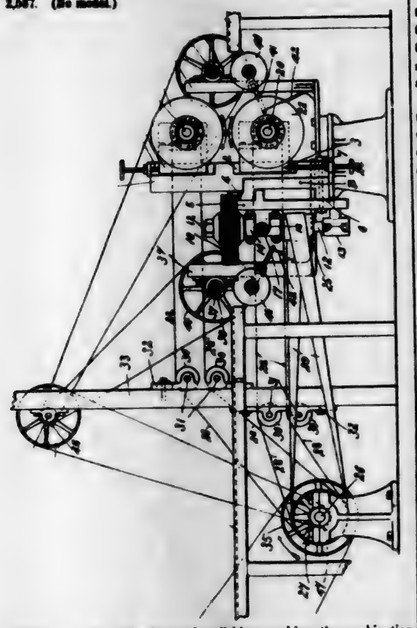


Claim.—1. A portable irrigator comprising a hollow staff, a piston, a rod for operating the piston, means for connecting the staff with a liquid-supply, a valve for cutting off the supply, hollow tines having latera openings connected to said hollow staff, and a valve for closing communication between said tines and staff.

2. A portable irrigator, comprising a hollow staff suitably connected with a liquid-supply, valves for controlling the admission to and emission from the staff of the liquid, a hollow fork-head having hollow tines formed with openings connect to said staff, and a piston for drawing the liquid into and discharging the same from the staff through tines.

3. A portable irrigator, comprising a hollow staff, a hollow fork-head having hollow tines formed with perforations and having thickened pointed ends, means for connecting said staff with a liquid-supply, and a piston for drawing the liquid into and discharging the same from said hollow staff.

708,127. GRINDING, POLISHING, OR BUFFING MACHINE. CHARLES F. CHURCH, Holyoke, Mass. Filed Jan. 24, 1900. Serial No. 2,567. (No model.)



Claim.—1. In a grinding and polishing machine, the combination with a vertical supporting-frame formed with upper and lower vertical slideways at its front, plates having flanges to engage the slideways and formed with upper and lower horizontally-projecting arms provided with bearing-apertures, bearing-boxes formed with trunnions mounted in said bearing-apertures, shafts in the bearing-boxes, upper and lower polishing-wheels on the shafts, and screws engaging said plates from above and below whereby the same may be adjusted to and from each other, substantially as shown and described.

2. In a grinding and polishing machine, the combination with the polishing-wheels, the feed-wheels, and the shaft thereof, of a polish-applying device comprising a lever formed to carry a polishing material in its free end, a roller on its other end, a spring to hold the polishing material in contact with the polishing-wheel, and a cam on the feed-wheel shaft to carry the lever with the polishing material free from the polishing-wheel, substantially as specified.

3. In a grinding and polishing machine, the combination with the polishing-wheels, of an automatically-operated device for applying polishing material to the wheels, comprising a suitably-mounted lever extended in both directions beyond its fulcrum or pivotal support, and formed to carry a polishing material in the end of the arm adjacent to the said wheels, a roller on the other arm of the lever, a cam to actuate the lever, and a spring to hold the roller in engagement with the cam.

4. In a grinding and polishing machine, a vertical supporting-frame formed with laterally-extended guideways at its base, laterally-adjustable plates formed with coincident grooves mounted on the guideways, and having rearwardly-projecting arms provided with bearings, vertically-disposed bearing-boxes formed with trunnions to rest within the bearings of said arms, lower vertical bearings carried by the plates, vertical shafts in the bearings, and polishing-wheels operatively mounted on the shafts.

5. In a grinding and polishing machine, a vertical supporting-frame formed with laterally-extended frames having guideways on their upper edges and provided with horizontally-elongated slots in the lower portion, laterally-adjustable plates formed with coincident grooves mounted on the guideways and having rearwardly-projecting arms provided with bearings, a fastening-bolt projected through the said slots, vertical bearing-boxes having trunnions to engage in the bearings of said arms, lower vertical bearings formed with an arm to engage in the said plates, vertical shafts in the bearings, and polishing-wheels operatively mounted on the shafts.

6. In a grinding and polishing machine, the combination of a relatively stationary feed-wheel, a lever suitably fulcrumed, a feed-roller journaled in one end of the lever and arranged adjacent to its companion roller, and a retractile spring secured to the other end of the lever.

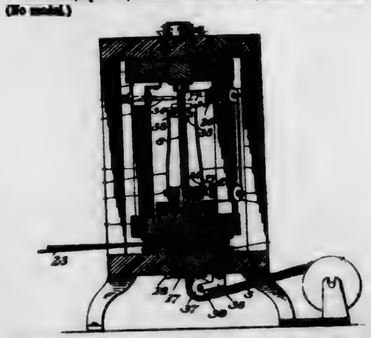
7. In a grinding and polishing machine, the combination with a vertically-disposed supporting-frame, and adjustable bearings supported by the frame, of upper and lower horizontally-arranged shafts mounted in the bearings at the front of the frame, vertical polishing-wheels on the shafts, vertical shafts mounted in the bearings at the rear of the frame, and horizontally-disposed polishing-wheels mounted on the vertical shafts.

8. In a grinding and polishing machine, the combination of a vertically-disposed supporting-frame, horizontal shafts mounted at the front of the frame, alining polishing-wheels on the shafts, vertical shafts mounted at the rear of the frame, alining polishing-wheels on the upper ends of the vertical shafts, feed-rollers at the front of the frame and polishing-wheels, and feed-rollers at the rear of the frame and rear polishing-wheels.

9. In a grinding and polishing machine, the combination with the shaft of the polishing-wheels, of bearing-boxes formed with trunnions, bearings to take the trunnions, a screw-threaded chamber in one of the bearings, a socket-plug having exterior screw-threads to engage those of the said chamber, and an expanding spring in the socket arranged to bear with one end on the end of the trunnion.

10. The combination in a polishing-machine, of a suitable frame, suitable polishing-wheels mounted thereon, and means for automatically and intermittently feeding one or more of the polishing-wheels with a polishing material, said means comprising a holder for the polishing material mounted upon a lever, a shaft having a cam as 54 mounted thereon revolving in engagement with one arm of the lever, and a spring arranged to maintain the engaging arm of the lever in contact with said cam, the cam being shaped to allow the holder of the polishing material to be carried toward the polishing-wheels as said cam revolves, and means to revolve the shaft upon which the cam is mounted, substantially as shown.

708,128. APPARATUS FOR THE CONTINUOUS MANUFACTURE OF SPIRAL SPRINGS OR COILS. ALFRED E. COLE and PATRICK J. DONNELLY, Spencer, Mass. Filed Oct. 16, 1901. Serial No. 78,802. (No model.)



Claim.—1. In an apparatus for coiling wire, the combination of a stationary non-rotating mandrel, means for leading the wire thereto, and mechanism for rotating the means around said mandrel, whereby the wire will be laid thereon, and formed into a spiral of indefinite length, which will slide off the end of said mandrel without rotation.

2. In an apparatus for coiling wire, the combination of a stationary non-rotating mandrel, a support for carrying a bundle of wire, means for leading the wire from said bundle to said mandrel, and means for rotating said support and said means, whereby the wire will be laid on said mandrel and formed into a spiral of indefinite length which will slide off the end of the mandrel without rotation.

3. In an apparatus for coiling wire, a stationary non-rotating mandrel, means for leading the wire thereto, a separator or spacer carried by said means, and mechanism for rotating this means around the mandrel.

4. In an apparatus for coiling wire, a hollow stationary non-rotating mandrel, means for leading the wire thereto, and mechanism for rotating this means around the mandrel to lay the wire thereon and form the coil.

5. In an apparatus for coiling wire, a stationary non-rotating mandrel having a shoulder, means for leading the wire to said mandrel to

wind on the same under said shoulder, and mechanism for rotating this means around the mandrel.

6. In an apparatus for coiling wire, a stationary non-rotating mandrel arranged to have its axis vertical, a support for a bundle or reel of wire arranged in line with the axis of said mandrel, and mechanism for rotating said means and support around said axis.

7. In an apparatus for coiling wire, the combination of a mandrel an escape-pipe arranged in line with said mandrel, a frame journaled on said mandrel and escape-pipe, means carried by said frame for leading the wire to the mandrel, and mechanism for rotating said frame.

8. In an apparatus for coiling wire, the combination of a mandrel, an escape-pipe arranged in line with said mandrel, disks journaled on said mandrel and escape-pipe, spider-arms connecting said disks, means carried by one of said spider-arms for leading the wire to the mandrel, and mechanism for rotating the frame formed by said disks and said arms.

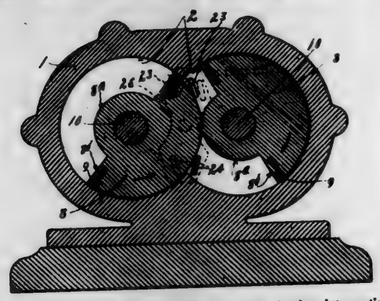
9. In an apparatus for coiling wire, a stationary non-rotating mandrel, a shoulder formed on said mandrel, means for leading the wire thereto mechanism for rotating the means around said mandrel, and a spacer carried by said means, arranged to fit in between the coils of the spiral to force the same off of the end of the mandrel as fast as it is laid under said shoulder, and to determine the pitch or spacing of the spring or coil.

10. In an apparatus for coiling wire, the combination of a stationary non-rotating mandrel having a working shoulder, said mandrel being slightly tapered from said shoulder, means for leading the wire thereto, and mechanism for rotating this means around the mandrel.

11. In an apparatus for coiling wire, a stationary non-rotating hollow mandrel having a working shoulder, means for leading the wire to said mandrel to lay the same under the shoulder, and mechanism for rotating this means around the mandrel.

12. In an apparatus for coiling wire, a mandrel, an escape-pipe, a frame journaled thereon, means for rotating the frame, and one or more pressers or formers carried by the end of the escape-pipe and pivoted thereon, so that they can be swung out, and the bundle or reel of wire placed on the end of the escape-pipe.

708,129. ROTARY ENGINE. ANDREW DAHLÉN, Vasa, Minn., assignor of one-half to H. L. Bryntilson and O. E. Anderson, Vasa, Minn. Filed Aug. 2, 1901. Serial No. 70,681. (No model.)



Claim.—1. The combination with a cylinder having intersecting piston-seats, of coöperating rotary pistons in said seats having reduced segmental sections intermeshing with the segmental body of the coöperating pistons, and admission and exhaust ports opening into and from the said cylinder and arranged to be opened and closed by said pistons, substantially as described.

2. The combination with a cylinder having intersecting piston-seats, and a pair of admission and a pair of exhaust ports one admission-port and one exhaust-port opening into each piston-seat through a cylinder-head, of coöperating segmental rotary pistons working in said piston-seats and serving as valves to open and close said ports in the proper order, substantially as described.

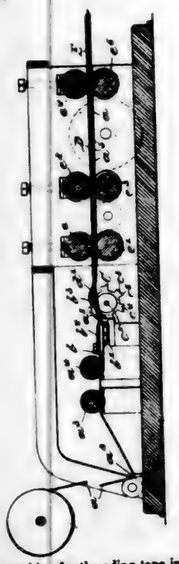
3. The combination with a cylinder having intersecting piston-seats and two pairs of admission and two pairs of exhaust ports opening into said cylinder, two admission-ports and two exhaust-ports opening to each piston-seat, of coöperating intermeshing rotary pistons working in said seats and serving as valves to open and close said ports in the proper order, and a pair of reversing-valves coöperating with said ports, substantially as described.

4. The combination with a cylinder having intersecting piston-seats and the pairs of admission and exhaust ports 21 22 and 23 24, respectively, of the reversing-valves 25 and 26 having respectively, the ports 21^a 22^a and 23^a 24^a, connections for moving said valves simultaneously, and the intermeshing segmental rotary pistons working in said seats and serving as valves to open and close said admission and exhaust ports in the proper order, substantially as described.

5. The combination with a cylinder having intersecting piston-seats and pairs of admission and exhaust ports opening into said piston-seats, of the reversing-valves coöperating with said admission and exhaust ports, the cut-off valve coöperating with said admission-ports, and the rotary segmental intermeshing pistons working in said seats and serving as valves to open and close said ports in the proper order, substantially as described.

6. The combination with a cylinder having intersecting piston-seats and suitable admission and exhaust ports, of rotary segmental intermeshing pistons working in said seats, and means for adjusting one of said pistons with respect to the other comprising the sliding bearing 14, the yoke 16 and the nutted bolt 17 18, substantially as described.

708,180. MACHINE FOR THREADING TAPE INTO EDGINGS. JONATHAN DAVIS, Phœnixville, Pa. Filed Apr. 24, 1902. Serial No. 104,494. (No model.)



Claim.—1. In a machine for threading tape into lace or edging, a wheel having radial projections, the peripheral face of said projections having a straight portion terminating in a finger, all arranged so that the distance between successive bars of the lace or edging to be fed is less than the distance between successive projections on said wheel.

2. In a machine of the character described, in combination with means for feeding the edging, a star-wheel, the projections of which having a straight face terminating in a finger, said straight face adapted to engage and to permit a movement of alternate bars of said lace or edging and to be rotated by said bars by abutting against said fingers.

3. In a machine of the character described, in combination with means for feeding the edging, a star-wheel having projections and straight faces terminating in a finger, the straight faces of said projections and the intervening spaces between the same adapted to receive and to permit a certain forward movement of the bars of said lace or edging.

4. In a machine of the character described, in combination with means for feeding the lace or edging, a star-wheel, the projections of which have straight faces and a finger, said faces adapted to engage alternate bars of said edging and to be rotated by said bars by abutting against said fingers with a step-like movement and to permit the entrance of the bars intermediate of said alternate bars in the intervening spaces of said projections, said spaces being of greater width than the width of a projection so as to afford a free movement of said intermediate bars independently and during and after the step-by-step movement of said star-wheel, and a needle located between said projections adapted to receive the alternate bars above and the intermediate bars below the point thereof.

5. In a machine of the character described, in combination with means for feeding the lace or edging, a star-wheel, the projections of which have straight faces and a finger arranged at one end of said straight face the faces being adapted to receive alternate bars of said lace or edging, and

to be rotated by said bars by abutting against each finger successively by a step-like movement, and the intervening spaces of said projection being of greater width than the width of each projection and adapted to receive intermediate bars of the alternate bars to permit an independent forward movement of said intermediate bars in said intervening spaces of said projections, a needle arranged between said projections, curved guides adapted to present the alternate bars of said lace or edging to one pair of the projections of said star-wheel to feed the alternate bars of said lace or edging upon the needle, and a tension-arm adapted to feed the intermediate bars of said lace or edging passing over said curved guides below said needle so as to interlace said bars with said needles.

6. In a machine of the character described, in combination with a needle adapted to receive the lace or edging and mechanism for feeding the lace or edging toward the needle, a star-wheel having projections and straight peripheral faces terminating in successive fingers integral with said projections, and intervening spaces between said projections of a width greater than the width of each projection, the flat faces of said projections and intervening spaces between the same adapted to receive and to present bars of the lace or edging alternately above and below the point of the needle, and said star-wheel so arranged as to be driven by alternate bars of said lace or edging by abutting against the fingers of said projections.

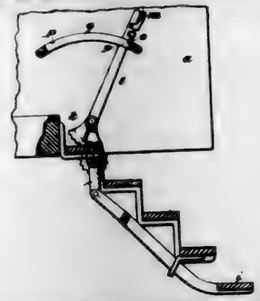
7. In a machine of the character described, in combination with a needle adapted to receive the lace or edging and mechanism for feeding the lace or edging over the needle and to maintain the same in a flat condition and taut position during said feeding, a star-wheel adapted to present the lace or edging to the needle so that the bars of the lace or edging are alternately above and below the point of the needle, said star-wheel arranged to be driven by the feeding of the lace or edging with a step-like movement, and means adapted to depress the bars of the lace or edging before and during presentation of the lace or edging to said star-wheel.

8. The combination, in a machine for inserting tape into lace or edging, of a flat grooved bar adapted to receive the tape, a needle and a star-wheel for feeding the lace or edging over the needle and the grooved bar and tape, said needle having a contracted and flat end for the reception of the grooved bar, and a spring adapted to clamp said bar to the contracted and flat end of said needle.

9. In a machine for threading tape into lace or edging, a star-wheel having a series of projections, each projection having a flat face terminating at one end in a finger, curved guides arranged adjacent to said star-wheel, said star-wheel and guides arranged in the path of the lace or edging in its passage through the machine, and means arranged between said guides and the projections of said star-wheel to depress the bars of said lace or edging as the same passes through the machine.

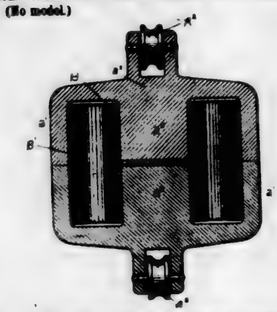
10. In a machine of the character described, a star-wheel having a series of radial projections separated from each other by a series of spaces wider than said projections, each projection having a flat face terminating at one end in a radial projecting finger, said spaces, flat faces and fingers mutually coöperating in the feeding of the lace or edging of the machine.

708,181. ATTACHMENT FOR CAR-STEPS. JAMES H. FARRELL, Nashua, and JOHN R. WARREN, Greenfield, N. H., assignors of one-half to William H. Chesver, Nashua, N. H. Filed Jan. 28, 1902. Serial No. 91,172. (No model.)



Claim.—The combination of a car-body; a flight of fixed steps secured thereto; a shaft journaled on said flight of steps; a crank-arm fast on the inner end of said shaft; a yoke pivotally secured to said crank-arm; guide-supports for said yoke; a step secured to said yoke; a pinion fast on the outer end of said shaft; a lever pivotally secured to said car-body and formed on its lower end with a segmental rack in mesh with said pinion, whereby motion is communicated to said shaft to raise and lower said yoke with its attached step; a strap secured to said car-body and formed with notches; a spring-controlled latch device mounted on the upper end of said lever for engaging in the notches in said strap, whereby said yoke is held in the desired position.

708,182. ELECTRIC-ARC LAMP. RICHARD FLEMING, Swampscott, Mass., assignor to General Electric Company, a Corporation of New York. Filed Dec. 6, 1900. Renewed Jan. 2, 1902. Serial No. 88,058. (No model.)



Claim.—1. A reactance-coil composed of an open-work cage of magnetic material having central cores separated by an air-gap, and a coil concentric with the cores and inside the cage.

2. A reactance-coil composed of a cage of magnetic material made in two similar parts united at the middle, and each carrying a central core, the ends of the cores being separated by an air-gap, and a coil concentric with the cores and inside the cage.

3. A reactance-coil composed of an open-work cage of magnetic material, having central cores separated by an air-gap, and a coil made in two sections concentric with the cores and having an annular space between them.

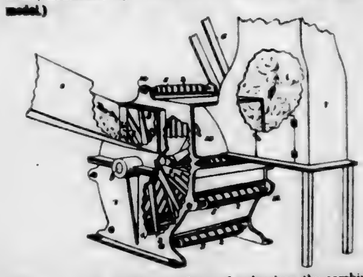
4. A frame for a reactance-coil for an arc-lamp, composed of the two similar parts A, A', each having a ring a, arms a' uniting in a hub a^3, and a core a^2 concentric with the ring a, the opposing ends of the cores having an air-gap between them.

5. The combination with a frame of magnetic material composed of the two parts A, A', having rings a, arms a' hubs a^3, cores a^2 having an air-gap between them, screws A^3, and insulating suspension-rings A^2, of the coil made in two sections B, B', one fitting the core and the other inside the arms, with a space between the coils.

6. In an electric-arc lamp, the combination of a cage or frame of magnetic material having central cores separated by an air-gap, a coil concentric with the cores mounted inside the cage or frame, and a tubular backbone depending from said cage or frame.

7. In an electric-arc lamp, the combination of a cage of magnetic material, a coil within the cage, and a tubular backbone secured to and depending from said cage.

708,188. MACHINE FOR CRUSHING FEATHERS AND PULVERIZING. FREDERICK FRANKE, Louisville, Ky., assignor to S. D. Crume, Louisville, Ky. Filed Nov. 26, 1901. Serial No. 83,587. (No model.)

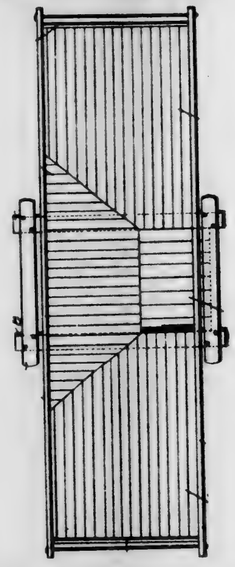


Claim.—1. In a feather crusher and pulverizer, the combination of a separable cylindrical casing, transverse rows of rectangular perforations through the periphery of said casing, bars of rectangular cross-section, having one end pivoted, passing through the said rectangular perforations in the casing, blocks of yielding material perforated and placed between the perforated outer ends of aforesaid bars, a bolt passing through the per-

forations of each row of blocks and bars, a sectional lining on the periphery of the casing consisting of blunt teeth cast integral with curved plates, a shaft passing axially through the casing and revolubly in boxes on the sides of the casing, a row of diametral bars keyed on said shaft and so spaced as to pass between the stationary bars and so disposed as to form a spiral, substantially as and for the purposes specified.

2. In a feather crusher and pulverizer, the combination of a cylindrical casing 1, transverse rows of arms 2 of rectangular cross-section, rigidly fastened in the periphery of said casing, a revolvable shaft 9 passing axially through said casing, a spiral row of tapered diametral arms 3 rigidly fastened to said revolvable shaft, a toothed peripheral lining 4 with teeth slanting opposite to the direction of motion of the revolving arms 3, an inlet-opening 8 in one side of the casing 1, and an outlet-opening in the periphery of the casing 1 on the side of said casing opposite to that having the inlet-opening, and a sliding shutter 10 to control the outlet-opening, substantially as and for the purpose specified.

708,134. DUMPING-WAGON. ROBERT J. GLEES, Verona, Ill. Filed May 28, 1902. Serial No. 109,376. (No model.)

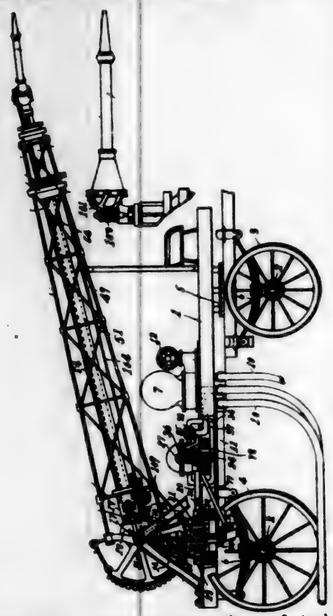


Claim.—1. A dumping-wagon comprising a body having a bottom composed of oppositely-inclined tapering end sections terminating short of the center and spaced apart thereat, and an oppositely-tapered transversely-inclined side section extending through the space between the inner ends of the end sections and forming a continuous incline from one side of the body to the other, sides depending from the body and forming with the extension of the side section, a discharge spout or chute, and a cut-off, substantially as described.

2. A dumping-wagon comprising a body having a bottom composed of inclined end sections terminating short of the center of the body, and an inclined side section having a central transverse extension extending downward between the ends of the end sections, cleats extending transversely of the body and supporting the lower ends of the end sections, side pieces arranged at the side edges of the central transverse extension of the inclined side section and projecting inward beyond the cleats to form supporting-shoulders, and a horizontal slide arranged on the supporting-shoulders, substantially as described.

3. A dumping-wagon comprising a body having a bottom composed of inclined end sections, and an inclined side section having a transverse extension extending downward at an inclination, transverse cleats secured to the wagon-body and extending beyond the same, side pieces arranged at the side edges of the extension and projecting inward beyond the cleats to form supporting-shoulders, a horizontal slide or cut-off arranged on the shoulders, and a horizontal bar arranged beneath the lower end of the extension and secured to the side pieces, substantially as described.

708,135. PORTABLE WATER-TOWER. HENRY H. GORTER, San Francisco, Cal., assignor to Mary E. Gorter, San Francisco, Cal. File Sept. 9, 1901. Serial No. 74,758. (No model.)



Claim.—1. In a water-tower, the combination of a truck, a swinging tower thereon, an extensible mast carried thereby, a motor on the truck and an operative connection between said motor and extensible mast to extend the same, said connection being flexibly jointed on an axis in line with the pivotal axis of the tower, substantially as described.

2. In a water-tower, the combination of a motor-shaft, a worm driven thereby, a shaft having a worm-wheel operated by said worm, a vertical shaft, said shafts having cooagaging bevaled gears, a swinging tower, a shaft swinging with said tower and connected with the vertical shaft by a knuckle-joint in line with the pivotal axis of the tower, an extensible portion for said tower and means operated by the swinging shaft for rotating said extensible portion, substantially as described.

3. In a water-tower, the combination of a motor, a worm driven thereby, an oblique shaft having a worm-wheel operated by said worm, a vertical shaft, said oblique and vertical shafts having cooagaging bevel-gears, a swinging tower, a shaft swinging with said tower and connected to the vertical shift by a knuckle-joint in line with the pivotal axis of the tower, an extensible portion for said tower, and means operated by the swinging shaft for actuating said extensible portion, substantially as described.

4. In a water-tower, the combination of a truck, a pivoted frame, a main tube carried thereon, a motor on the truck, a shaft driven thereby, a vertical shaft operatively connected with said motor-shaft to be driven thereby, said vertical shaft having a flexible connection substantially in line with the pivotal axis of the frame, a mast extensible from the main tube, and means for extending said mast operated by said vertical shaft, substantially as described.

5. In a water-tower, the combination of a truck, a pivoted frame, a main tube carried thereon, a water-wheel, means for supplying pressure-water to said water-wheel, a vertical shaft operatively connected with said water-wheel shaft to be driven thereby, said vertical shaft having a flexible joint substantially in line with the pivotal axis of the frame, a mast extensible from the main tube, and means for extending said mast, operated by said vertical shaft, substantially as described.

6. In a water-tower, the combination of a truck, a pivoted frame, a main tube carried thereon, a receiver, a conduit and flexible coupling for connecting the receiver with the main tube, means for supplying pressure-water to the receiver from the fire-hose, a water-wheel, a fluid or brush pipe from the receiver to the water-wheel to supply pressure-water thereto to operate the same, a vertical shaft operatively connected with said water-wheel shaft to be driven thereby, said vertical shaft having a flexible joint substantially in line with the pivotal axis of the frame, a mast

extensible from the main tube, and means for extending said mast operated by said vertical shaft, substantially as described.

7. In a water-tower, the combination of standards, a tower swinging thereon, a transverse shaft, an operative connection from the transverse shaft to the tower to swing the same, an extensible mast carried by said tower, means mounted loosely on the transverse shaft connected operatively to the extensible mast to extend the same, a motor-shaft, and means for connecting said motor-shaft with the transverse shaft and with the means mounted loosely thereon, substantially as described.

8. In a water-tower, the combination of standards, a tower swinging thereon, a transverse shaft, an operative connection from the transverse shaft to the tower to swing the same, a hollow motor-shaft loosely mounted on said transverse shaft, an extensible mast carried by said tower, means mounted loosely on the transverse shaft connected operatively to the extensible mast to extend the same, and clutches on said transverse shaft, arranged to be thrown into engagement with the hollow motor-shaft, one of said clutches connecting said motor-shaft with the transverse shaft to swing the tower, and the other being arranged to engage the means for extending the mast, substantially as described.

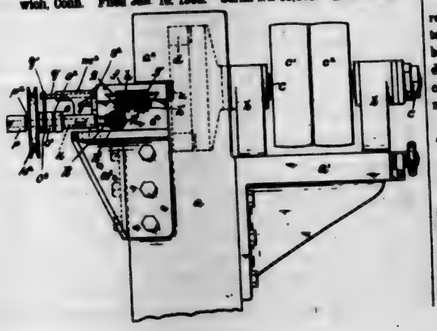
9. In a water-tower, the combination of standards, a tower swinging thereon, segmental gears carried by said tower, worms engaging said gears, longitudinal shafts carrying said worms, worm-wheels on said shafts, a transverse shaft having worms engaging said worm-wheels, a motor-shaft mounted loosely on said transverse shaft, an extensible mast carried by said tower, a worm mounted loosely on the transverse shaft, an operative connection from said worm to said extensible mast to extend the same, and clutches on said transverse shaft arranged to be thrown into engagement with the motor-shaft, one of said clutches connecting said motor-shaft with the transverse shaft to swing the tower by means of said segmental gears and the other being arranged to engage the worm to extend the mast, substantially as described.

10. In a water-tower, the combination of a tube, a mast extensible thereon, a casing at the lower end of the tube, a ring at the upper end of the tube rigidly connected with said casing, an internal gear-wheel revolvable about the lower end of said tube, gear-wheels engaged by said internal gear, worms on the gear-wheel shafts, vertical worm-wheels operated by said worms, pulleys attached to said worm-wheels, a ring revolvable in the upper ring, pulleys carried by said revolvable ring, and chains passed around said pulleys and attached to said mast to extend the same, substantially as described.

11. In a water-tower, the combination of a tube, a mast extensible thereon, a casing at the lower end of the tube, a ring at the upper end of the tube rigidly connected with said casing, a ring revolvable in the upper ring, a wheel revolvable about the lower end of the tube, pulleys carried by the ring and chain-pulleys carried by the wheel, chains passed around said pulleys and attached to the mast to extend the same, and means for revolving the chain-pulleys, substantially as described.

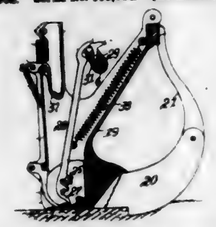
12. In a water-tower, the combination of the tower proper, a pivoted support thereon, a vertical shaft swinging with said tower, means for rotating said shaft, a main tube carried by said tower, a mast extensible thereon, means for extending said mast operatively connected with said swinging shaft, a gear-wheel mounted loosely on said swinging shaft, means for operating said gear-wheel, a nozzle upon the end of said mast, an extensible shaft, and means for supporting the same parallel with said tube and mast, an operative connection between the upper end of said extensible shaft and the nozzle to swing the same, and an operative connection between said gear-wheel and the lower end of said extensible shaft to rotate the same to swing the nozzle, substantially as described.

708,186. STOP-MOTION FOR CUTLERY-GRINDING MACHINES. ADDISON GOULD, Norwich, Conn., assignor to William A. Breed, Norwich, Conn. Filed Jan 10, 1902. Serial No. 89,171. (No model.)



Claim.—In combination with a shaft *k*, a constantly-rotating pulley loosely mounted on said shaft, clutch mechanism connecting the said shaft and pulley, a reciprocating table, and means for disconnecting the said clutch consisting of a rod *q*, fork *q'*, and a hinged latch carried by the said reciprocating table, substantially as herein specified.

708,187. CORN-PLANTER. LEVI P. GRAHAM, Decatur, Ill. Filed June 5, 1902. Serial No. 110,334. (No model.)



Claim.—1. In a planter, the combination of a seed-conveying shank adapted to travel along the surface of the soil, a seed-retaining bucket hinged in the lower end of the shank with its bottom extended horizontally rearward from the hinge, and means for forcing the rearward extension of the bucket into the soil below the shank and discharging the seed into the depression made by the bucket.

2. In a planter, the combination of a seed-conveying shank adapted to travel along the surface of the soil, a seed-retaining bucket composed of sides and a bottom, such bucket being hinged in the lower end of the shank with its bottom extended rearward from the hinge, and a push-bar to force the rearward extension of the bucket into the soil below the shank and discharge the seed into the depression formed by the bucket.

3. In a planter, the combination of a seed-conveying shank adapted to travel along the surface of the soil, a seed-retaining bucket composed of sides and a bottom, such bucket being hinged in the lower part of the shank with its bottom extending rearward from the hinge, a push-bar pivotally connected with the bucket at a point above and to the rear of the hinge, and an extension of the push-bar approximately reaching the bottom of the bucket and acting as a seed-discharger therefor.

4. In a planter, the combination of a seed-conveying shank adapted to travel along the surface of the soil, a seed-retaining bucket composed of sides and a bottom, such bucket being hinged in the lower part of the shank with its bottom extending rearward from the hinge, a push-bar pivotally connected with the bucket at a point above and to the rear of the hinge, an extension of the push-bar approximately reaching the bottom of the bucket and forming a seed-discharger therefor and a valve pivoted in the shank in the rear of the push-bar with its lower end in position to close the rear end of the bucket, when the bucket is raised.

5. In a planter, the combination of a seed-conveying shank adapted to travel along the surface of the soil, a seed-retaining bucket hinged in the lower end of the shank with its bottom extended rearward from the hinge and its rear lower part projecting beyond the walls of the shank, and means for forcing the rearward extension of the bucket into the soil below the shank.

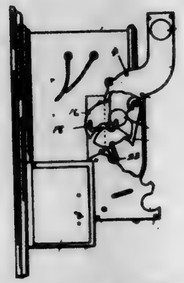
6. In a planter, the combination of a seed-conveying shank, a seed-retaining bucket hinged in the lower end of the shank with its bottom extending rearward from the hinge, means for forcing the rearward extension of the bucket into the soil below the shank and a furrow-forming runner attached to the lower end of the shank with its lower edges above the soil-penetrating position of the rearward extension of the bucket.

7. In a planter, the combination of a seed-conveying shank, a seed-retaining bucket hinged in the lower end of the shank with its bottom extended rearward from the hinge, a push-bar connecting pivotally with the bucket and extending upward therefrom, and a rock-arm adapted to press downward on the push-bar to force the bucket into the soil and swing closer of the push-bar when the bucket is at the end of its downward movement.

708,138. COIN-CONTROLLED TELEPHONE. SYLVESTER P. GREY, Fort Wayne, Ind., assignor of one-half to Franklin Howenstein, Fort Wayne, Ind. Filed Oct. 14, 1901. Serial No. 78,530. (No model.)

Claim.—1. In a coin-controlled telephone a coin-chute having a longitudinal coin-channel provided at its lower end with two discharge-openings one of which is controlled by an adjustable slide; a coin-arresting disk rotatably mounted in the said chute in cooperative relation with an actuating receiver-hook; a receiver-hook engaging said disk and adapted to automatically actuate the same when the receiver is removed therefrom; means for limiting the forward movement of the said disk against

the stress of the said hook; an adjustable slide closing one of the discharge-openings of said chute; means for arresting the coin upon the said slide; and means for withdrawing said slide from the path of the descending coin.



2. A coin-chute having two discharge-openings one of which is normally closed; a coin-arresting disk revolubly mounted in said chute in co-operative relation with an actuating receiver-hook; a receiver-hook engaging said disk and adapted to automatically actuate the same when the receiver is removed therefrom; means for limiting the forward movement of the said disk against the stress of the said hook; means for again arresting the said coin at or near its point of discharge; means for normally closing one of said discharge-openings; and means for enabling the telephone operator to open said closed opening for the purpose described.

3. In a coin-chute having a vertically-disposed coin-channel provided with two independent outlet-ports, a laterally-adjustable slide arranged in said chute to normally close one of said ports, and having a vertical slot adapted to register with the coin-channel; movable means independent of said slide for normally arresting the coin upon the said slide; and means for actuating the said slide under the control of the central operator for the purpose described.

4. In a device of the class specified a coin-arresting disk revolubly mounted in a coin-chute having a peripheral coin-arresting recess and a pair of peripheral lugs as described; a receiver-hook arranged in an actuating engagement with the said disk; a spring-pressed pawl mounted in said chute in a co-operative relation with the said disk as described; and means for withdrawing the said pawl from its holding engagement with the said disk consisting of a screw-threaded lug on the rear face of said pawl and a key adapted to fit the same.

708,139. MECHANICAL MUSIC-CHART. CHRISTINE M. HALVORSEN, Los Angeles, Cal. Filed May 3, 1900. Serial No. 15,864. (No model.)

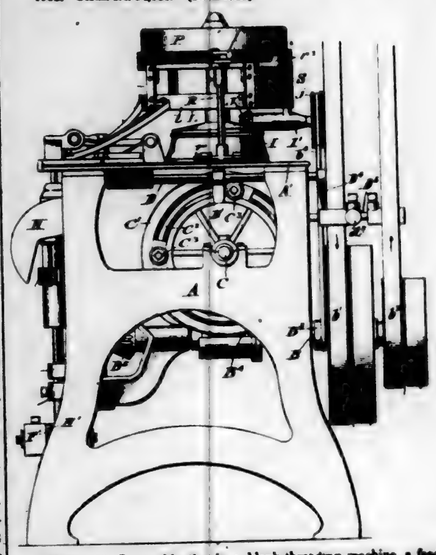
Claim.—1. A mechanical music-chart comprising a sheath of woven fabric tapering slightly from one end toward the other and furnished with stitching for the lines of a music-staff and which can be readily detached if desired from the frame; and independent tone-indicating music characters respectively provided with a pointed pin to insert into said fabric.

2. A mechanical music-chart comprising an open frame with four limbs or members united at the corners of the frame; a sheath of woven fabric stretched over the frame; said furnished with the lines of a music-staff and music characters respectively furnished with pointed pins which are inserted into the fabric to hold the characters in place.

3. A mechanical music-chart, comprising a sheath of woven fabric tapering slightly from one end toward the other and furnished with the lines of the music-staff; and a tapering frame to fit the sheath tightly.

4. A mechanical music-chart, comprising a sheath of woven fabric tapering slightly from one end toward the other, and furnished on its opposite side with the lines of the music-staff; a frame composed of four limbs joined at the corners and tapering to fit the sheath tightly; means for closing the mouth of the sheath; and a detachable band around the sheath outside the frame, substantially as set forth.

708,140. FEED MECHANISM FOR BLANK-THREADING MACHINES. JAMES H. HASKINS, Chicago, Ill., assignor of one-half to McCormick Harvesting Machine Company, Chicago, Ill. Filed Feb. 19, 1902. Serial No. 94,813. (No model.)



Claim.—1. In combination in a blank-threading machine, a feed-chute for the blanks, a feed-bar moving across said chute, a finger on said bar adapted to simultaneously engage and deflect the foremost blank in the chute and arrest the movement of the blanks in the chute, a plunger for forcing the deflected blank to the top and operating at right angles to the feed-bar, and means to successively advance the feed-bar and the plunger.

2. In combination in a blank-threading machine, a feed-chute for the blanks, which chute is formed with a deflected section, a feed-bar reciprocating across said chute, a finger on said bar adapted to simultaneously advance a blank along said deflected chute-section and arrest the movement of the blanks in the main chute, a plunger operating across the deflected section to force the blank from the deflected section and over the top, and means to successively advance the feed-bar and the plunger.

3. In combination in a blank-threading machine, a feed-chute for the blanks, which chute is provided with a deflected section at its lower end, a feed-bar having a finger reciprocating across said chute adapted to simultaneously advance a blank along the deflected section of said chute and arrest the movement of the blanks in the main chute, a plunger operating across said chute-section to force the blank from the deflected section and over the top, an actuator-bar connected to said plunger and said feed-bar, whereby the feed-bar and the plunger are alternately operated to advance the blank.

4. In combination in a blank-threading machine, a feed-chute for the blanks, which chute is provided with a deflected section at its lower end, a feed-bar having a finger reciprocating across the chute and adapted to simultaneously advance a blank along the deflected section of said chute and arrest the movement of the blanks in the main chute, a plunger operating across said chute-section to force the blank from the deflected section and over the top, an actuator-bar operatively connected to said plunger, and a rock-lever pivoted between said actuator-bar and said feed-bar, whereby the latter is operated by said actuator-bar, all so arranged that when the plunger is advanced to force a blank over the top, the feed-bar is retracted to uncover the chute and upon the reverse movement of the plunger the feed-bar is advanced to close the chute and advance the next blank.

5. In combination in a blank-threading machine, a hopper containing the blanks, a series of feed-chutes delivering the blanks from the hopper to the tops, each chute having a deflected section at its lower end, a feed-bar reciprocating across said chutes, a series of spring-pressed fingers mounted upon said feed-bar and normally closing the respective chutes, reciprocating plungers for the respective chute-sections, and an actuator-bar connected with the several plungers and with the feed-bar, whereby the blanks are advanced along the deflected sections of the chute by the feed-bar fingers and subsequently forced over the tops by the plungers.

6. In combination in a blank-threading machine, a hopper containing the blanks, a series of chutes delivering the blanks from the hopper to the tops, each chute having a deflected section at its lower end, a plunger reciprocating across each of said deflected chute-sections to force the blank therefrom and over the corresponding top, an actuator-bar, yielding safety connections between the actuator-bar and the respective plungers, whereby the latter are reciprocated, a feed-bar having a series of fingers reciprocating along said deflected chute-sections to advance the foremost blank in each chute and arrest the movement of the blanks in the main chutes, and means connected with said actuator-bar to retract the feed-bar and cause the fingers thereon to uncover the respective chutes for the delivery of another blank into each of the deflected chute-sections.

7. A blank-feeding mechanism comprising a chute having a deflected section, a plunger reciprocating across said deflected section, a feed-bar mounted above and transversely of said chute, said bar comprising a stationary sleeve, a reciprocating rod mounted in said sleeve, a collar on said sleeve and connected with said rod, a finger on said collar operating in said deflected chute-section and normally closing the main chute, and means for advancing and retracting said plunger and said feed-bar alternately, whereby a single blank is fed from the chute, advanced by the finger along said deflected chute-section, and forced over the top by the plunger.

8. A blank-feeding mechanism comprising a series of chutes, each having a deflected section at its end, a plunger reciprocating across each of said deflected sections, a feed-bar mounted above and transversely of said chutes, said feed-bar comprising a stationary sleeve, a reciprocating rod mounted in said sleeve, a series of collars loosely mounted on said sleeve and detachably connected to said rod, springs surrounding said sleeves and operating to hold said collars and said rod in engagement, and fingers on the collars operating in the deflected sections of the chutes, and means for advancing and retracting said plungers and said feed-bar alternately, whereby a single blank is fed from each chute, advanced by the co-operating finger-bar along the deflected chute-sections and forced over the top by the corresponding plunger.

708,141. EYEGLASSES. ALBERT E. HAWKES, Atlanta, Ga. Filed Jan. 16, 1902. Serial No. 90,028. (No model.)

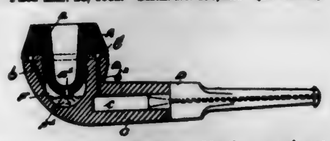
Claim.—1. A spring-bow for eyeglasses, comprising two separate spring members, a series of detents formed in said members, and a horn depending from the end of each member adapted to engage the detents in the other member and lock the members against movement.

2. In combination with the bows of eyeglasses, the connecting-spring made in two separate parts, bands carried by the upper end of each spring, the bands of one spring adapted to encircle the other spring, and means mounted upon each of said bands adapted to clasp the spring passing under it.

3. In combination with the bows of eyeglasses, the connecting-spring made in two separate parts, bands carried by the ends of each spring, the band of one spring adapted to encircle the other spring, of a ratchet connection between said bands and said springs.

4. In combination with the bows of eyeglasses, the connecting-spring made in two separate parts, a series of detents or seats formed in said spring and a band carried by the end of each spring; a horn depending from each of said bands and a ball secured upon the lower end of each horn adapted to engage the said series of detents or seats.

708,142. TOBACCO-PIPE. MARSHALL B. HEES, Birmingham, England, assignor to John Horn and Marie Horn, Manchester, England. Filed Mar. 22, 1902. Serial No. 100,622. (No model.)



Claim.—1. In a tobacco-pipe, the combination consisting of an outer bowl part B having an annular groove b' on its upper end and diametrically-opposed passages $b\,b^2$ through its body respectively putting the said annular groove into communication with a sump F at the bottom of B and with the aperture c in the pipe-stem C, and an inner bowl part A detachably connected with B and communicating with the said sump F in the same but preventing the smoke from flowing up around its exterior and thence directly to the said passage b^2, substantially as described.

2. In a tobacco-pipe, the combination consisting of an outer bowl part B having an annular groove b' in its upper end and diametrically-opposed passages $b\,b^2$ through its body respectively putting the said annular groove into communication with a sump F at the bottom of B with the aperture c in the pipe-stem C, an inner bowl part A detachably connected with B and communicating with the sump F in the same but preventing the smoke from flowing up around its exterior and thence directly to the said passage b^2, and a metal washer A′ disposed between the said parts A and B to prevent their adhesion, substantially as described.

708,143. ROLLING-HOOP. EDWARD P. KINSMAN, North Andover, Mass. Filed Nov. 20, 1901. Serial No. 83,013. (No model.)

Claim.—The combination with a hoop, of inclosed pockets constituting chords of an arc of the hoop, and balls or similar free objects in the pockets.

708,144. ELEVATING AND DUMPING APPARATUS. RUSSELL HOLLOPETER, Fostoria, Ohio. Filed Nov. 30, 1901. Serial No. 84,288. (No model.)

Claim.—1. The combination with the derrick or frame and the bucket and its elevating devices, of a counterbalance-weight for the bucket, an inclined plane for throwing out the lower end of the bucket, and means for automatically dumping the same when it reaches the limit of its upward movement, as set forth.

2. The combination with the frame or derrick and the bucket and its elevating devices, of an inclined plane for throwing out the lower end of the bucket, means for turning the bucket from its elevating position to one at substantially a right angle thereto, and means for returning the bucket to a position to descend, as set forth.

3. The combination with the frame or derrick, the bucket and its elevating devices, of means for stopping the upward movement of the bucket and means including an inclined plane for automatically dumping the same.

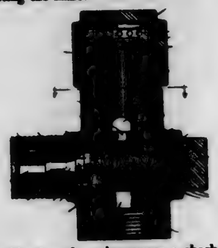
4. The combination with the frame or derrick and the bucket and its elevating devices, of means for automatically stopping the upward movement of the bucket, a pivoted frame, and a weight guided in an inclosure in said frame for returning the bucket to its position to descend.

708,145. VALVE. BARRY IVES and JAMES S. WARD, Chicago, Ill. Filed Nov. 21, 1901. Serial No. 83,117. (No model.)

Claim.—1. A combined check and relief valve comprising a valve-casing, a check-valve chamber in said casing, a check-valve in said chamber, a relief-valve chamber in said casing communicating with said check-valve chamber, and a relief-valve in said relief-valve chamber, said valve-chambers communicating with an opening in the valve-casing for admitting steam to close said check and relief valves.

2. The combination of a check-valve, a vacuum-relief valve, a valve-

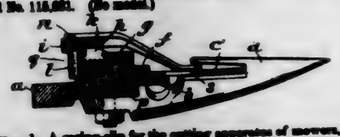
casing, a check-valve chamber in said casing, a relief-valve chamber in said casing, an opening in said casing communicating with said valve-chambers, a spring for closing said check-valve and a sleeve inclosing said spring for protecting the same.



3. The combination of a valve-casing, a check-valve, a vacuum-relief valve, a check-valve chamber in said casing, a relief-valve chamber in said casing, said chambers communicating one with another, an opening in said casing for admitting steam into said check-valve chamber, a spring for closing said check-valve, and a perforated cap for admitting air into said relief-valve chamber.

4. The combination of a valve-casing, a check-valve, a check-valve chamber, a relief-valve chamber, a wall in said casing for supporting said relief-valve when open, an opening in said casing for admitting steam therefrom, connections between said steam-opening and said check-valve chamber, an aperture in said wall for admitting steam into said relief-valve chamber and a recess in one extremity of said relief-valve registering with said aperture in said wall.

708,146. CUTTING APPARATUS FOR MOWERS, REAPERS, OR THE LIKE. EDWARD A. JOHNSTON, Chicago, Ill., assignor to McCormick Harvesting Machine Company, Chicago, Ill. Filed July 10, 1902. Serial No. 115,621. (No model.)



Claim.—1. A spring-clip for the cutting apparatus of mowers, reapers, and the like, comprising a rigid finger extending forward over the cutter and free to oscillate therewith, and a spring holding said finger down with an elastic pressure on the cutter.

2. A spring-clip for the cutting apparatus of mowers, reapers, and the like, comprising a rigid spring-pressed finger that is free to oscillate on a vertical pivot, combined with a spring which causes the finger to tilt on a horizontal fulcrum and presses its front end elastically down on the cutter.

3. A spring-clip for the cutting apparatus of mowers, reapers, and the like, comprising a rigid bell-crank-shaped finger that is pivoted horizontally and vertically by one of its arms and has its other arm extending forward over the cutter, combined with a spring which acts on the first-mentioned arm to hold the forwardly-extending arm elastically down on the cutter.

4. A spring-clip for the cutting apparatus of mowers, reapers, and the like, comprising a rigid, pivoted, spring-pressed finger overhanging the cutter and having a lug on the under side of its front end, combined with a cutter having a fore-and-aft slot into which the lug extends and in which it plays as the cutter and finger reciprocate.

5. A spring-clip for the cutting apparatus of mowers, reapers, and the like, comprising a rigid finger *h* having a pivot *l* with a V-shaped recess in the rear side at the upper end, a socket *g* having a knife-edged projection *n* at its upper rear side, and a spring *p* inclosed in the socket and resting against the lower end of the pivot *l*.

6. A spring-clip for the cutting apparatus of mowers, reapers, and the like, comprising a rigid finger *h*, having a pivot *l* with a V-shaped recess *m* in the rear side at the upper end, a socket *g* having a rear wall *i* with a knife-edged vertical projection *n*, and a spring *p* inclosed in the socket and resting against the lower end of the pivot *l*, the forward end of the finger having a projection on its under side to engage a slot in the cutter.

708,147. CUTTING APPARATUS FOR MOWERS, REAPERS, OR THE LIKE. EDWARD A. JOHNSTON, Chicago, Ill., assignor to McCormick Harvesting Machine Company, Chicago, Ill. Filed July 10, 1902. Serial No. 115,622. (No model.)

Claim.—1. A spring-clip for the cutting apparatus of mowers, reapers, and the like, comprising a base-plate having a vertical pivot-post, a rigid finger pivoted upon said post and extending forward over the cutter and free to oscillate therewith, and a spring reacting between the post and the finger to hold the latter down elastically on the cutter.

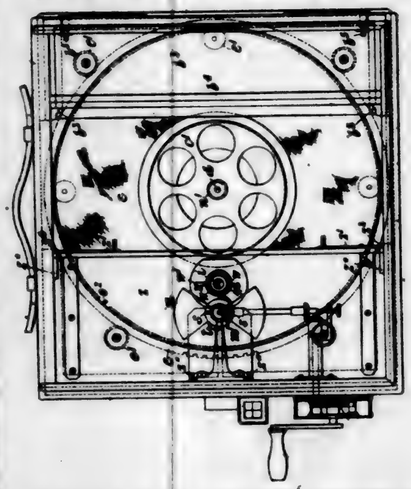
2. A spring-clip for the cutting apparatus of mowers, reapers, and the like, comprising a base-plate having a vertical pivot-post, a rigid finger having a pair of perforated ears at its rear end by means of which it is pivoted on the post so as to oscillate freely, and a spring coiled around the post between the ears and reacting between the post and the lower ear to hold the finger down so that its forward end which projects over the cutter is held elastically down thereon.

3. A spring-clip for the cutting apparatus of mowers, reapers, and the like, comprising a base-plate having a vertical pivot-post, a rigid finger pivoted upon said post and extending forward over the cutter and free to oscillate therewith, a washer on the pivot-pin, and a coiled spring reacting between the washer and the finger to hold the front end of the latter down elastically on the cutter.

4. A spring-clip for the cutting apparatus of mowers, reapers and the like, comprising a base-plate *d*, having a vertical post *f*, a rigid finger *g* pivoted on said post to oscillate freely and having its front end extending forward and bearing down on the cutter, and a spring *w* coiled around the post, the finger having a pair of perforated ears *h*, *h'*, by means of which it is pivoted to the post, and a washer *s* or other projection on the post under the upper ear and between which and the lower ear the spring reacts.

5. The combination with one of the cutters of a mower, reaper, or the like, of a clip comprising a spring-depressed finger having a nib or projection on its forward end, and a groove or depression formed in the cutter into which the nib engages so that the finger is oscillated by the reciprocations of the cutter.

708,148. APPARATUS FOR PHOTOGRAPHING AND EXHIBITING KINEMATOGRAPHIC PICTURES. LEONARD U. KARR, London, England. Filed July 22, 1902. Serial No. 116,032. (No model.)



Claim.—1. In apparatus for photographing and exhibiting kinematographic pictures the combination of an outer casing, a lens connected to the said casing, an intermittently-rotated picture-plate, a toothed ring and spiral cam for effecting the intermittent rotation of the picture-plate, a rectilinearly-sliding plate carrying the said picture-plate and moving it relatively with the lens and telescoping through one end of the outer casing and a rack-bar and pinion for effecting the rectilinear movement of the sliding plate substantially as described.

2. In apparatus for photographing and exhibiting kinematographic pictures the combination of an outer casing, a lens connected to the said casing, an intermittently-rotated picture-plate, a toothed ring and spiral cam for effecting the intermittent rotation of the picture-plate, a rectilinearly-sliding plate carrying the said picture-plate and moving it relatively with the lens and telescoping through one end of the outer casing, a rack-bar and pinion for effecting the rectilinear movement of the sliding plate and wall upon the sliding plate where it telescopes through the outer casing to prevent the disclosure of the picture-plate substantially as described.

3. In apparatus for photographing and exhibiting kinematographic pictures, the combination of an outer casing, a lens connected to the said casing, an intermittently-rotated ring-shaped picture-plate, a rectilinearly-sliding plate carrying the said picture-plate and moving it relatively with the lens and telescoping through one end of the outer casing, a toothed ring supporting the picture-plate upon the rectilinearly-sliding plate, a clamping-disk, a shaft for operating mechanism for moving the sliding plate rectilinearly, a rack and pinion comprising such mechanism, a disk connected to the said shaft on the side of the picture-plate opposite to that of the clamping-disk and against which the picture-plate is designed to be clamped and means carried by the said shaft for securing the clamping-disk against the picture-plate substantially as described.

4. In apparatus for photographing and exhibiting kinematographic pictures, the combination of an outer casing, a lens connected to the said casing, an intermittently-rotated ring-shaped picture-plate, a rectilinearly-sliding plate carrying the said picture-plate and moving it relatively with the lens and telescoping through one end of the outer casing, a toothed ring supporting the picture-plate upon the rectilinearly-sliding plate, a clamping-disk, a shaft for operating mechanism for moving the sliding plate rectilinearly, a rack and pinion comprising such mechanism, a disk connected to the said shaft on the side of the picture-plate opposite to that of the clamping-disk and against which the picture-plate is designed to be clamped, a nut loosely connected with the clamping-disk and a screw-thread on the said shaft for the engagement of the nut, substantially as described.

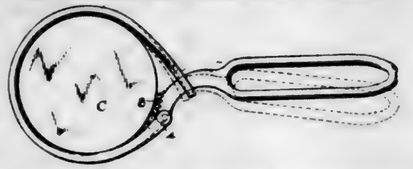
5. In apparatus for photographing and exhibiting kinematographic pictures, the combination of an outer casing, a lens connected to the said casing, an intermittently-rotated picture-plate, a rectilinearly-sliding plate carrying the said picture-plate and moving it relatively with the lens and telescoping through one end of the outer casing a toothed ring supporting the picture-plate, means for moving the picture-plate rectilinearly, an operating-handle, gear-wheels and spiral cam for intermittently rotating the picture-plate and a telescopic driving device for the spiral cam, one portion of which device is carried by the case of the apparatus and the other part by the rectilinearly-sliding plate carrying the picture-plate substantially as described.

6. In apparatus for photographing and exhibiting kinematographic pictures, the combination of an outer casing, a lens connected to the said casing, an intermittently-rotated picture-plate, a rectilinearly-sliding plate carrying the said picture-plate and moving it relatively with the lens and telescoping through one end of the outer casing a toothed ring supporting the picture-plate, means for moving the picture-plate rectilinearly, an operating-handle, gear-wheels and spiral cam for intermittently rotating the picture-plate and a telescopic driving device for the spiral cam comprising a shaft carried by the case of the apparatus, a fork on the said shaft, a disk engaging the said fork and a shaft carrying the disk and supported on the rectilinearly-sliding plate carrying the picture-plate substantially as described.

7. In apparatus for photographing and exhibiting kinematographic pictures, the combination of an outer casing, a lens connected to the said casing, an intermittently-rotated picture-plate, a toothed ring and spiral cam for effecting the intermittent rotation of the picture-plate a rectilinearly-sliding plate carrying the said picture-plate and moving it relatively with the lens and telescoping through one end of the outer casing, a rack-bar and pinion for effecting the rectilinear movement of the picture-plate, a lever pivoted to the case of the apparatus and jointed to the rack-bar and means whereby it can be clamped upon its fulcrum, substantially as and for the purpose set forth.

8. In apparatus for photographing and exhibiting kinematographic pictures, the combination of an outer casing, a lens connected to the said casing, an intermittently-rotated picture-plate, a toothed ring and spiral cam for effecting the intermittent rotation of the picture-plate a rectilinearly-sliding plate carrying the said picture-plate and moving it relatively with the lens and telescoping through one end of the outer casing a rack-bar and pinion for effecting the rectilinear movement of the picture-plate, a lever pivoted to the case of the apparatus and jointed to the rack-bar, a bolt, a nut engaging therewith and a slotted plate fixed to the case of the apparatus and through which the bolt passes substantially as and for the purpose set forth.

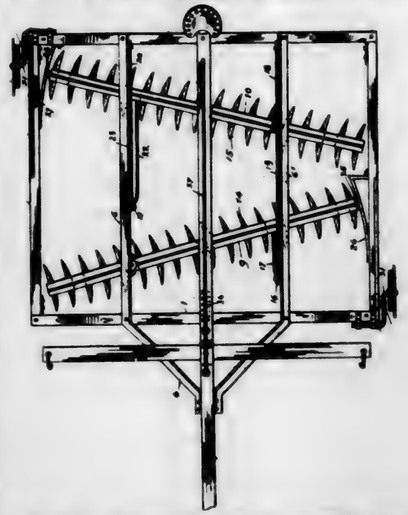
708,149. FRUIT-CAN WRENCH. WILLIAM F. KERR, Cleveland, Ohio. Filed Feb. 20, 1902. Serial No. 95,497. (No model.)



Claim.—1. A fruit-jar wrench consisting of a spring-metal loop having an elongated slot at one end and a handle having a curved shank loosely projected through said slot and slidable thereon and pivotally engaged at its extremity with the opposite end of said loop, the said shank having its convex portion on the inside in respect to the loop and provided with serrations at its base inside to bear against the article to be gripped, substantially as described.

2. The wrench described consisting of a malleable metallic loop having a slot lengthwise at one end and ears at the other end with opposite lugs on their inside, in combination with the handle having a segmentally-curved shank extending through said slot and engaged between said ears, the concave edge of said shank being on the outside, substantially as described.

708,150. CULTIVATOR. ANDERS H. KOPPERUD, Byron, Cal. Filed Feb. 20, 1902. Serial No. 94,677. (No model.)



Claim.—1. A disk harrow comprising a frame, a pair of axles suspended therefrom, said axles being arranged one in advance of the other, the axles being pivotally connected at opposite ends to the frame, means connected to the free end of the axles for changing the position thereof, a series of colter-disks secured to each axle, and colter-wheels connected to the frame at diagonally opposite corners.

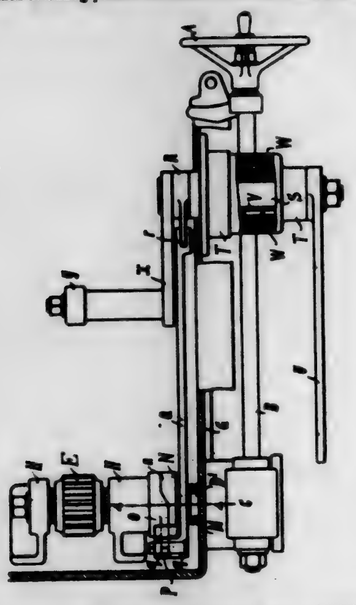
2. The combination with the frame, of a pair of axles suspended therefrom one in advance of the other, said axles being pivotally connected at opposite ends to the frame, means connected with the free end of each axle whereby the same may be swung into different positions, a series of colter-disks secured to each axle, and segment-plates attached to the frame and against which the free ends of the axles bear.

708,151. ORDNANCE. JOSEF KUBS, Essen, Germany, assignor to Fried. Krupp, Essen, Germany. Filed Jan. 9, 1902. Serial No. 88,905. (No model.)

Claim.—1. The combination of an elevating device for guns locking the gun in an adjusted firing position, and mechanism disengaging the gun from the elevating device and moving the gun independently of the elevating device from an adjusted firing position to loading position and thence to the same firing position.

2. The combination of an elevating device for guns, a clutch in con-

section with said elevating device, and means operating the clutch and moving the gun independently of the elevating device, from an adjusted firing position to loading position and thence to the same firing position.



3. The combination of an elevating device for guns, a clutch interposed between the driving and driven parts of said elevating device, mechanism through which the breech of the gun is manipulated up and down independently of the elevating mechanism, and a connection between the breech-shifting means and the clutch, throwing the clutch out as the breech is shifted to loading position, and in when the gun reaches its original firing position.

4. In combination with a gun, an elevating mechanism, a clutch interposed between the driving and driven parts of the elevating mechanism and means for throwing the clutch in and out, consisting of the ring N, and the sleeve O having engaging faces formed at an inclination, one of said parts being connected with the movable member of the clutch and the other having a fixed abutment, and means for imparting relative rotation between said parts.

5. In a gun-mount, elevating mechanism embodying in its structure a two-part shaft, with a clutch interposed between and having its members respectively fixed and sliding on the parts of said shaft, a worm-gear rotating said shaft, a spring on said shaft bearing against the sliding clutch member, and the ring and sleeve having angularly-disposed engaging faces, and arranged the one in connection with the movable clutch member, and the other in abutment with a fixed part, and means for rotating said sleeve.

6. In a gun-mount, an elevating mechanism holding the gun in adjusted firing position and embodying a clutch between its driving and driven parts; a shaft having a crank-arm providing a movable support for the breech of the gun, independent of the elevating mechanism, and connections between the shaft and the clutch.

7. In a gun-mount, an elevating mechanism holding the gun in adjusted firing position embodying a clutch between its driving and driven parts; and a shaft having a crank-arm providing a movable support for the breech of the gun, independent of the elevating mechanism, and a counterbalance-spring on said shaft tending to rotate the crank in a direction to raise the gun-breech.

8. In a gun-mount, an elevating mechanism embodying a clutch between its driving and driven parts, and a shaft having a crank-arm providing a movable support for the breech of the gun, and a crank-and-rod connection between the shaft and clutch moving the latter into and out of engagement as the supporting-crank moves.

9. In a gun-mount, the combination of the toothed arc, connected with the gun, the toothed gear engaging said arc, the two-part shaft, one part of which carries said toothed gear, the clutch interposed between the two parts of said shaft, the ring and sleeve having inclined engaging faces, and connected the one to the movable member of the clutch and the other to a fixed part, and disengaging the clutch when they are relatively rotated, the shaft near the breech of the gun carrying a lever which raises and lowers said breech and with a hand-lever for manipulating it, and the lever-and-rod connection between the last-named shaft and the clutch-operating sleeve; a lost motion being provided between the manipulating hand-lever and the breech-supporting crank, whereby upon movement of the hand-lever in one direction the clutch is first disengaged and the gun-breech moved, and upon movement of the hand-lever in the opposite direction the gun-breech is moved and the hand-lever is reengaged.

708,152. DIFFERENTIAL-GEAR PULLEY-BLOCK. RENARD LAVERY, Boston, Mass. Filed Mar. 20, 1901. Serial No. 52,442. (No model.)

Claim.—1. In a pulley-block, in combination, a differential-gear operating-wheel, a lifting sheave or set of sheaves, and means adapted to automatically throw off the differential power and allow the use of the lifting sheave or sheaves as a direct simple pulley, substantially as specified.

2. In a pulley-block, in combination, a differential-gear operating-wheel, a lifting sheave or set of sheaves, means adapted to automatically throw off the differential power and allow the use of the lifting sheave or sheaves as a direct simple pulley, and means whereby the load may be held suspended at any point when the differential power is so thrown off, substantially as specified.

3. In a pulley-block, in combination, a differential-gear operating-wheel, a lifting sheave or set of sheaves, means adapted to automatically throw off the differential power and allow the use of the lifting sheave or sheaves as a direct simple pulley, and means for braking the said lifting sheave or sheaves, substantially as specified.

4. In a pulley-block, in combination, a differential-gear operating-wheel, a lifting sheave or set of sheaves, means adapted to automatically throw off the differential power and allow the use of the lifting sheave or sheaves as a direct simple pulley, means whereby the load may be held suspended at any point when the differential power is so thrown off, and means for braking the said lifting sheave or sheaves, substantially as specified.

5. In a pulley-block, in combination, a differential-gear operating-wheel, a lifting sheave or set of sheaves, a ratchet and pawl adapted to automatically throw off the differential power and allow the use of the lifting sheave or sheaves as a direct simple pulley, substantially as specified.

6. In a pulley-block, in combination, a differential-gear operating-wheel, a lifting sheave or set of sheaves, a ratchet and pawl adapted to automatically throw off the differential power and allow the use of the lifting sheave or sheaves as a direct simple pulley, and means for braking said lifting sheave or sheaves, substantially as specified.

7. In a pulley-block, in combination, a differential-gear operating-wheel, a lifting sheave or set of sheaves, a ratchet and pawl adapted to automatically throw off the differential power and allow the use of the lifting sheave or sheaves as a direct simple pulley, and means adapted to lock said pawl in said ratchet until said ratchet is given a slight reverse impulse, substantially as specified.

8. In a pulley-block, in combination, a differential-gear operating-wheel, a lifting sheave or set of sheaves, a ratchet and pawl adapted to automatically throw off the differential power and allow the use of the lifting sheave or sheaves as a direct simple pulley, means adapted to lock said pawl in said ratchet until said ratchet is given a slight reverse impulse, and means for braking said lifting sheave or sheaves, substantially as specified.

9. In a pulley-block, in combination, a differential-gear operating-wheel, a chain-pocketed lifting-sheave, accessory unpocketed lifting-sheaves, and a ratchet and pawl, the said ratchet being secured to a gear meshing with one side of the aforesaid differential gearing, substantially as specified.

10. In a pulley-block, in combination, a differential-gear operating-wheel, a chain-pocketed lifting-sheave, accessory unpocketed lifting-sheaves, a ratchet and pawl, the said ratchet being secured to a gear meshing with one side of the aforesaid differential gearing, a friction-wheel secured to one of the lifting-sheaves, and a hand-brake bearing upon said friction-wheel, substantially as specified.

11. In a pulley-block, in combination, a differential-gear operating-wheel, a chain-pocketed lifting-sheave, accessory unpocketed lifting-sheaves, a ratchet and pawl, the said ratchet being secured to a gear meshing with one side of the aforesaid differential gearing, the ratchet-notches adapted to lock said pawl in said ratchet until said ratchet is given a slight reverse impulse, substantially as specified.

12. In a pulley-block, in combination, a differential-gear operating-wheel, a chain-pocketed lifting-sheave, accessory unpocketed lifting-sheaves, a ratchet and pawl, the said ratchet being secured to a gear meshing with one side of the aforesaid differential gearing, ratchet-notches adapted to lock said pawl in said ratchet until said ratchet is given a slight reverse impulse, a friction-wheel secured to one of the lifting-sheaves, and a hand-brake bearing upon said friction-wheel, substantially as specified.

13. In a differential-power pulley-block, means adapted to automatically throw off the differential power and allow the use of the lifting sheave or sheaves as a direct simple pulley.

708,153. OAR ATTACHMENT. MOSES A. LESSER, Pullman, Ill. Filed Dec. 11, 1901. Serial No. 85,515. (No model.)

Claim.—1. The combination with an oar, of an auxiliary flexible power-transmitting device connected at one end to the oar at a point outboard from the loom, and an engaging loop disposed at the opposite end of said device.

2. The combination of an oar, flexible means attached to said oar at a point outboard from the loom for directly transmitting auxiliary force thereto, said means being provided with a loop for engagement by an assistant.

3. The combination of an oar, an adjustable strap for directly transmitting auxiliary force to said oar, said strap being attached at one end to said oar at a point outboard from the loom and having a loop at its other end provided with a stirrup.

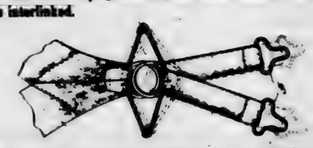
4. An oar attachment comprising a strap provided with means at one end for removably engaging an eye on an oar at a point outboard from the loom, and at the other end with an adjustable loop having a stirrup.

5. The combination of an oar, a plate attached to said oar outboard from the loom and having a series of eyes disposed thereon, and a strap provided with means for removably engaging said eyes.

6. The combination of an oar, a plate attached to said oar outboard from the loom and having a series of eyes disposed thereon, and a strap provided with means for removably engaging said eyes, said strap also having a stirrup attached thereto.

708,154. SUSPENDERS. CHARLES O. LEAH, Brandon, Vt. Filed Jan. 2, 1902. Serial No. 88,602. (No model.)

Claim.—1. In a pair of suspenders, a draft-evener for connecting the shoulder and button straps, comprising two separate coiled springs, having their terminals projected beyond their coils and the ends of the terminals interlinked.



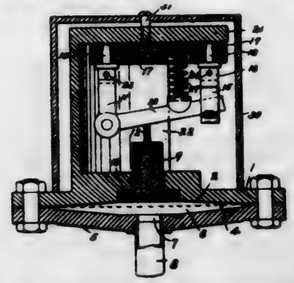
2. In a pair of suspenders, a draft-evener for connecting the shoulder and button straps, comprising two separate coiled springs, the terminals of which are oppositely disposed and projected beyond the coils, and interlinked at their extremities.

3. In a pair of suspenders, a draft-evener for connecting the shoulder and button straps, comprising two separate springs having the extremities of their terminals connected and their intermediate portions provided with whirls disposed intercurrent.

4. In a pair of suspenders, a draft-evener comprising two separate coiled springs having their terminals projected beyond the coils and the ends of the terminals interlinked, button-straps secured to the coils of the lower member, and a flexible band secured to the coils of the upper member and to the shoulder-strap buckle.

5. In a pair of suspenders, a draft-evener for connecting the shoulder and button straps comprising two oppositely-operable coiled springs having their terminals projecting beyond their coils and connected at their extremities.

708,155. ELECTRIC ATTACHMENT. JONATHAN C. HILOSE, Providence, R. I., assignor to the General Fire Extinguisher Company, New York, N. Y., a Corporation of New York. Filed Mar. 1, 1898. Serial No. 672,102. (No model.)



Claim.—1. The combination with a pressure-chamber, of a diaphragm therein, a plunger operated thereby, a block of insulating material, binding-posts depending therefrom and supported thereby, an overhanging arm to which said block is secured, a contact-blade pivoted to one of said posts and engaged by said plunger, and plates secured to the other post between which said blade passes.

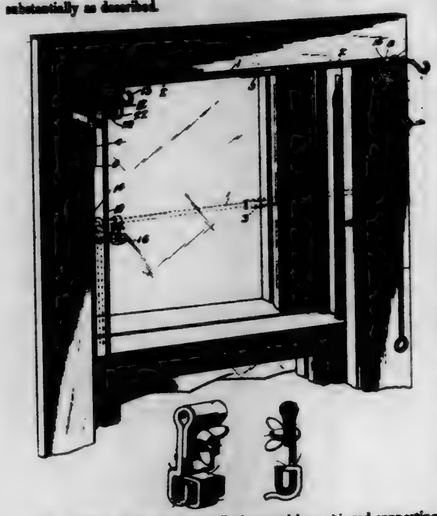
2. The combination with two dished plates, a diaphragm clamped between said plates, an inlet through one plate, a plunger extending through the second plate and engaging the diaphragm, a standard projecting from the second plate, an arm extending laterally from said standard, a block of insulating material secured to the under face of said arm, binding-posts depending from said block, and a contact-blade engaged by said plunger for connecting said posts.

3. The combination with dished plates 1 and 5, of a diaphragm 3 clamped between said plates, an inlet 7 to the chamber 6 below the diaphragm, a standard 22 rising from plate 1, an arm 21 extending laterally from said standard, a block 17 of insulating material secured to the under side of said arm, binding-posts 11 and 16 supported by said block, a contact-blade 12 pivoted to post 11, plates 15 carried by post 16, and a plunger 9 engaging diaphragm 3 and contact-blade 12.

708,156. WINDOW-SHADE HANGER. JAMES B. HEREN, Hattenburg, Miss. Filed Nov. 22, 1901. Serial No. 83,310. (No model.)

Claim.—1. A device of the class described comprising a supporting-frame designed to be hinged to a window-frame and adapted to swing upward and downward, brackets carried by the frame and adapted to support a curtain-shade, and rods forming handles and provided with eyes receiving the frame, said rods being also provided with arms arranged to support a curtain-pole, substantially as described.

2. A device of the class described comprising a supporting-frame provided with arms designed to be hinged to a window-frame at opposite sides thereof and capable of swinging upward and downward, brackets carried by the frame and adapted to support a curtain-shade, rods hinged to the frame and forming handles for operating the same and provided with arms arranged to support a curtain-pole, a catch arranged at one side of the frame in position for engaging the same and adapted to hold the said frame in an elevated position, and a support located below the catch and arranged to receive the frame when the latter is swung downward, substantially as described.



3. A device of the class described comprising a hinged supporting-frame arranged to swing upward and downward, means for holding the frame in an elevated position, brackets carried by the frame, one of the brackets being provided with an eye and the other bracket having a substantially U-shaped bearing portion, and a resilient clamp detachably mounted on the bearing portion of the bracket and extending across the said bearing portion from the exterior of one side and terminating at the inner face of the opposite side, substantially as described.

4. A device of the class described comprising a frame, a bracket carried by the frame and provided with an approximately U-shaped bearing portion, and a resilient clamp extending across the top of the bearing portion of the bracket and having a hook-shaped lower portion engaging the bottom of the bracket, substantially as described.

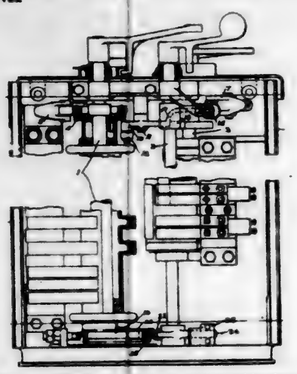
5. A device of the class described comprising a frame, a bracket carried by the frame and provided with an approximately U-shaped bearing portion and having a shoulder at the top thereof, and a resilient clamp interlocked with the bracket at the bottom thereof and having an upper portion extending across the bearing portion of the bracket from the exterior of one side and terminating at the inner face of the opposite side and engaging the shoulder, substantially as described.

708,157. CONTROLLER FOR ELECTRIC MOTORS. FRANK A. MERRICK and HERBERT W. STULL, Johnstown, Pa., assignors to the Lorain Steel Company, a Corporation of Pennsylvania. Filed Jan. 2, 1902. Serial No. 88,691. (No model.)

Claim.—1. In a controller for electric motors, the combination of a rheostatic switch, a series-parallel switch, a lock for the series-parallel switch temporarily released by the movement of the rheostatic switch to a predetermined running position, and a second lock for the series-parallel switch released by the return of the rheostatic switch to its open-circuit position.

2. In a controller for electric motors, the combination with separately-operable rheostatic and series-parallel switches, of a lock for the series-parallel switch controlled by the rheostatic switch and released by the movement of the latter through its operative position and back to its open-circuit position.

3. In a controller for electric motors, the combination with a rheostatic switch, and a separately-operable series-parallel switch, of a lock for the series-parallel switch controlled by the operation of the rheostatic switch and released by a movement of the latter through its operative positions and back to its open-circuit position, and means connected with said lock and operating automatically to render it again effective after a short interval.



4. In a controller for electric motors, the combination of a rheostatic switch, a series-parallel switch, separate means for operating the two switches, and a spring tending to hold the series-parallel switch at its series position, of a locking-pawl engaging the said series-parallel switch, means on the rheostatic switch for disengaging said pawl when the rheostatic switch is moved to its off position, a spring for returning said pawl to locking position after such disengagement, and a retarding device opposing the action of said spring.

5. In a controller for electric motors, the combination with a rheostatic switch, a separate series-parallel switch, means for normally holding the series-parallel switch at its series position, of a locking device for locking said switch in that position, and means operated by the rheostatic switch for disengaging said locking device, a spring tending to reengage said locking device, and a retarding device opposing the action of said spring.

6. In a controller for electric motors, the combination with a rheostatic switch, a separate series-parallel switch, means for normally holding the series-parallel switch at its series position, of a locking device for locking said switch in that position, and means operated by the rheostatic switch for disengaging said locking device, a spring tending to reengage said locking device, and a retarding device opposing the action of said spring, together with a second locking device also engaging the series-parallel switch, and released only when the rheostatic switch is at its open-circuit position.

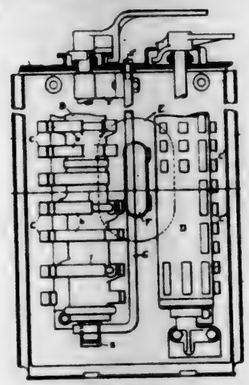
7. In a controller for electric motors, the combination of a rheostatic switch, a separately-operative series-parallel switch, a spring normally holding said series-parallel switch at its series position, a locking-pawl for locking said series-parallel switch in both series and parallel positions, means on the rheostatic switch whereby at its open-circuit position said lock is released, a second locking-pawl engaging the series-parallel switch and locking it in series position, means on the rheostatic switch for releasing said pawl when the rheostatic switch is at its last running position, a spring tending to reengage the last-named pawl, and a retarding device acting in opposition to the said spring.

8. In a controller for electric motors, the combination with separate rheostatic and series-parallel switches, and locking devices for the series-parallel switch controlled by the rheostatic switch, of an electromagnetic device operated by current generated by one or more of the motors for modifying the action of said lock under certain conditions.

9. In a controller for electric motors, the combination with separate rheostatic and series-parallel switches, and locking devices for the series-parallel switch controlled by the rheostatic switch and normally requiring a full operation of the rheostatic switch for their release, of a magnet-coil, means whereby the movement of the rheostatic switch to its off position places said coil in circuit with the armature of one of the motors, and an armature for said magnet arranged, when the magnet is energized, to restrain the normal action of the locking devices.

10. In a controller for electric motors, the construction of separate rheostatic and series-parallel switches, a spring tending to hold the series-parallel switch at its series position, a lock for holding the series-parallel switch at multiple position, means whereby said lock is normally released when the rheostatic switch is at open-circuit position, a magnet, a circuit for the coil of said magnet including one of the motor-armatures, and closed by the rheostatic switch at its off position, and an armature for said magnet arranged to engage the series-parallel switch when the latter is at its multiple position and prevent its return to series position so long as the magnet remains sufficiently energized.

708,158. CONTROLLER FOR ELECTRIC MOTORS. FRANK A. MERRICK and HERBERT W. STULL, Johnstown, Pa., assignors, by mesne assignments, to Westinghouse Electric and Manufacturing Company, Pittsburg, Pa., a Corporation of Pennsylvania. Filed Jan. 2, 1902. Serial No. 88,692. (No model.)



Claim.—1. In a controller for electric motors, the combination with a casing formed in part of magnetic material, and a controller-drum whose body and shaft are also of magnetic material, of a blow-out coil, a core supporting said coil, and a pole-piece carried by said core and carrying the bearings for the said shaft.

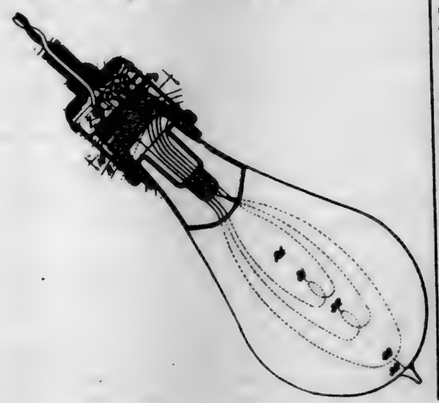
2. In a controller for electric motors, the combination with a contact-carrying drum having a body of magnetic material, of a blow-out coil adjacent to the central portion of said drum, a pole-piece carried by the said core, and carrying the bearings for the shaft of said drum, and a casing arranged to complete the magnetic circuit through the said drum.

3. In a controller for electric motors, a blow-out coil adjacent to a contact-carrying drum of the controller, a pole-piece carried by the core of said coil, and bearings for the shaft of said drum carried by the said pole-piece.

4. In a controller for electric motors, the combination of a casing having its body portion formed of magnetic material, a contact-carrying drum having its body and shaft of magnetic material, a blow-out coil adjacent to the central portion of said drum, a core for said coil carried by the said casing, a pole-piece for said coil carried by the casing and itself carrying the bearings for the said shaft.

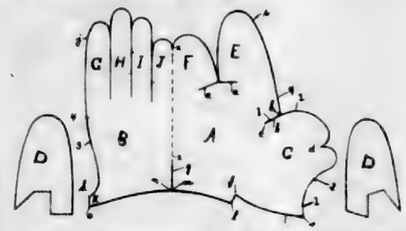
5. In a controller for electric motors, the combination with a contact-carrying drum having its shaft and body portion composed of magnetic material, a blow-out coil, and a pole-piece secured to the core of said coil and extending in opposite directions therefrom parallel with and adjacent to the said drum, and bearings for the drum-shaft carried by the said pole-piece.

708,159. INCANDESCENT LAMP. HENRY E. REYNER, Butte, Mont. Filed Aug. 19, 1901. Serial No. 73,603. (No model.)



Claim.—An incandescent lamp, comprising a casing, a cap therefor, a sleeve in the cap, a screw-plug in the sleeve, an insulating-collar at the lower end of the casing, a threaded metallic socket in the collar, an insulating-plate secured to said socket, a conductor extending through the plug and electrically connected through said plate to said metallic socket, a series of spring-contacts, below said plate, electrical conductors connected thereto, a globe, a threaded plug, an insulating-lining for the plug and securing the globe in position, filaments in the globe electrically connected at one end to said plug, and segmental contact-strips embedded in and projecting upward from said lining, and connected to the opposite ends of said filaments, each of which is adapted to engage, once in each revolution, one of said spring-contacts, substantially as described.

708,160. GLOVE. DANIEL F. MORGAN, Toledo, Ohio. Filed Mar. 17, 1902. Serial No. 98,587. (No model.)



Claim.—1. A hand-covering comprising front and back portions and a thumb portion formed from a single blank said thumb portion consisting of a convex portion and an ogee-curved portion, said convex portion being adapted to be fastened to said ogee-curved portion in such a manner as to form a perfect-fitting thumb.

2. A hand-covering comprising front, back and thumb portions in one piece, said thumb portion commencing at a point near the apex of the angle formed by the thumb and index-finger and consisting of an outwardly, downwardly and inwardly extending convex portion; a second outwardly, downwardly and inwardly extending convex portion, which gradually changes to a prolonged inwardly, downwardly and outwardly extending concave portion, said convex portions meeting at a curvilinear angle; and a third inwardly and slightly upwardly extending portion which joins the lower point of said second portion at an angle, the outlines of said first and second portions being such as to form a perfect-fitting thumb when properly joined together.

3. In a hand-covering comprising front and back portions, a thumb portion integral with said front portion and consisting of an outwardly, downwardly and inwardly extending convex portion, a second outwardly, downwardly and inwardly extending convex portion which gradually changes to a prolonged inwardly, downwardly, and outwardly extending concave portion, said convex portions meeting at an angle, and a third inwardly and slightly upwardly extending convex portion, which joins the lower point of said second portion at an angle; said back portion having its outer edge concave near its lower extremity and adapted to join with said inwardly and slightly upwardly extending convex portion to provide a perfect fit around the wrist and heel of the thumb.

4. A hand-covering comprising front, back and thumb portions, the said back portion having the edge *j k* which tapers gradually inwardly and downwardly and suddenly outwardly near its lower portion, thereby forming the tongue K, the said edge *j k* being adapted to join with the edges *f e* and *h i* and the edge *k o* with the edge *l f*.

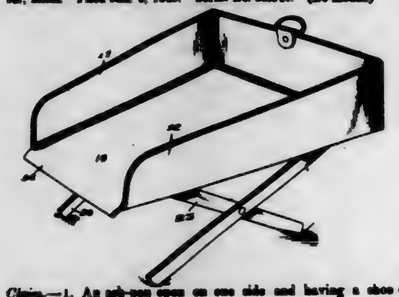
5. In a hand-covering comprising front, back and thumb portions formed from a single blank, and a wrist portion, said front and back portions being hollowed out adjacent to said wrist portion in such manner that when said front and back portions are folded upon each other said wrist portion joins said front and back portions at a slight angle, substantially as described.

708,161. TOOL FOR BANDING BOXES. PATRICK W. MULLANY, Amberg, Wis. Filed Nov. 15, 1901. Serial No. 82,629. (No model.)

Claim.—A tool for banding boxes comprising a bar or member 1 provided at one end with a recess, a steel plate detachably secured to the bar or member 1 adjacent to the said recess and provided with a cutting edge at one side and having a cam edge at its outer end, said bar or member 1 being also provided with a terminal cam edge located opposite the cam edge of the detachable plate, and the bar or member 2 pivoted between the plate and the bar or member 1 and provided at the inner side of the pivotal point with a cutting edge to cooperate with that of the plate, said bar or member 2 being enlarged beyond the cam edges to form

supporting side shoulders and having diverging arms arranged in the same longitudinal planes as the said shoulders and adapted to straddle a strap or band, substantially as described.

708,162. SAFETY ASH-PAN. TIMOTHY F. O'CONNOR, Sauk Center, Minn. Filed Jan. 6, 1902. Serial No. 88,647. (No model.)



Claim.—1. An ash-pan open on one side and having a shoe or guideway 50 on the under side of its bottom, two pairs of supporting-legs, crossed and pivotally connected together, fixed bearings pivotally connecting one pair of said legs to the bottom of the pan, a cross-bar having downwardly-extending bearings for the other pair of legs, and a bar 42, extending inwardly from the cross-bar, operating in the shoe or guideway and having means to adjustably secure it therein, substantially as described.

2. An ash-pan having two pairs of supporting-legs crossed and pivotally connected together, fixed bearings pivotally connecting one pair of said legs to the bottom of said pan, slidable bearings pivotally connecting the other pair of said legs to said pan, a guide for said slidable bearings, means to secure the latter when adjusted, and laterally-extending ears 24 at the outer ends of one pair of said legs, at the under sides thereof, substantially as described.

708,163. SEAT-HINGE. LEWIS D. PEYER, Chicago, Ill. Filed May 22, 1901. Serial No. 61,449. (No model.)

Claim.—1. In a seat-hinge, an immovable part A having a central opening B and provided with a stud *a*; a seat-arm provided with a projection *d* having groove E and track F in its circumferential face, said projection of seat-arm resting upon stud *a* of immovable part A within groove E; movable abutment C having a track H therein; a spring K interposed between movable abutment C and side *a'* of immovable part A; a ball I interposed between the movable abutment C and projection *d* within tracks H and F in each respectively, substantially as specified.

2. The combination of a seat-arm provided with a projection having track and groove therein, an immovable part having a central opening and a recess therein and also provided with a stud extending into said central opening and upon which stud the projection of seat-arm rests and turns within said groove in the circumferential face of the projection of seat-arm, a movable abutment having a V-shaped track therein for a ball placed in said recess in immovable part, a ball interposed between the circumferential face of projection of seat-arm and movable abutment in tracks in each respectively, a spring yieldingly holding movable abutment in working position, substantially as specified.

3. The combination of a seat-arm having a projection with a groove and track in the circumferential face of such projection, an immovable part provided with a central opening and a recess and a stud having a concave top surface upon which the projection of seat-arm rests and turns, a movable abutment set in said recesses in the opening of said immovable part and provided with a track therein for a ball, a ball interposed between the projection of seat-arm and the movable abutment in said tracks in each respectively, and a spring yieldingly holding movable abutment in a working position and confined in its limit of operation by immovable part, substantially as specified.

4. An immovable part having a central opening and a recess and provided with a stud having a concave top surface; a seat-arm provided with a projection having a groove in its circumferential face and also having a V-shaped track, each track being lenticular in form, the sides thereof converging at either end at an acute angle, and placed on the opposite circumferential face of such projection to said groove; a movable abutment placed in said recess in immovable part and provided with a lenticular V-shaped track the sides of which track converge at either end at an acute angle; a ball interposed between the projection of seat-arm and the movable abutment within said tracks in the circumferential face of such projection and movable abutment respectively, and a spring yieldingly holding the movable abutment in a working position, substantially as specified.

5. An immovable part molded as part of a seat-standard, having a central opening and a recess, also a stud having a concave top; a seat-arm provided with a projection, such projection having a groove within which the stud of the immovable part is placed, and upon which stud the projection turns, such groove being concentric throughout its greater part to the concave top of such stud, said projection also provided with a V-shaped track placed in the circumferential edge of said projection opposite to such groove, said track being lenticular in shape the sides thereof converging at either end at an acute angle; a movable abutment placed in said recess in immovable part of hinge, said abutment having a track therein which track is lenticular in form, the sides thereof converging at either end at an acute angle, said abutment being so placed in immovable part that the track therein shall be opposite to and facing the track in the projection of seat-arm; a spring yieldingly holding abutment in working position, and a ball interposed between movable abutment and the circumferential face of projection of seat-arm, substantially as specified.

708,164. MEANS FOR LOADING AUTOMATIC PHOTOGRAPHIC APPARATUS. GEORGE H. PEYER, Cleveland, Ohio, assignor to the American Automatic Photograph Company, Cleveland, Ohio, a Corporation of Ohio. Filed Oct. 25, 1901. Serial No. 79,994. (No model.)

Claim.—1. Means for loading photographic apparatus, comprising the combination of a receptacle adapted to carry a column of photographic plates, a removable closure at one end of said receptacle, and means embodied in said receptacle for removing such closure.

2. Means for loading photographic apparatus comprising the combination of a receptacle, adapted to carry a column of photographic plates, a removable closure at one end of said receptacle, and means embodied in said receptacle for moving said column of plates in said receptacle, whereby said closure may be removed.

3. Means for loading photographic apparatus comprising the combination of a receptacle, adapted to carry a column of photographic plates, a removable closure at one end of said receptacle, and a movable cap at its opposite end whereby said closure may be removed by the movement of said cap when a column of plates is in said receptacle.

4. Means for loading photographic apparatus, comprising the combination of a receptacle adapted to carry a column of photographic plates, a removable closure at one end of said receptacle having a flexible peripheral portion, and means embodied in said receptacle for removing said closure.

5. Means for loading photographic apparatus, comprising the combination of a receptacle adapted to carry a column of photographic plates, a removable closure at one end of said receptacle, and a movable cap at its other end whereby said column may be removed by the movement of said cap when a column of plates is in said receptacle.

6. Means for loading photographic apparatus, comprising the combination of a receptacle, adapted to carry a column of photographic plates, a removable closure at one end of said receptacle, a movable cap at its other end, and a separator adapted to rest intermediately of said cap and said column of plates, whereby said closure may be removed by the movement of said cap when a column of plates is in said receptacle.

7. In means for loading photographic apparatus, the combination of a receptacle adapted to carry a column of photographic plates, a movable cap at one end of said receptacle and a detached member adapted to rest intermediately of said cap and a column of plates, and adapted to pass through said receptacle.

8. In means for loading photographic apparatus, a receptacle adapted to carry a column of photographic plates, a removable light-tight closure adapted to fit within the interior of one end of said receptacle, a movable cap at the other end of said receptacle and means embodied in said receptacle for removing said closure.

708,165. PHOTOGRAPHIC PLATE. GEORGE H. PEYER, Cleveland, Ohio, assignor to the American Automatic Photograph Company, Cleveland, Ohio, a Corporation of Ohio. Filed Oct. 26, 1901. Serial No. 79,993. (No model.)

Claim.—1. A photographic sensitive plate having a mount permanently confined thereto and flanged so as to overlap the edge of the plate both in front and rear, substantially as specified.

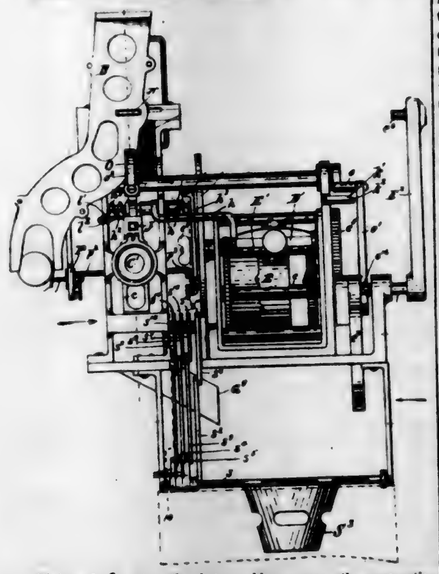
2. A photographic sensitive plate having a mount consisting of a backing-plate with edge flange lapped around the edge of the sensitive plate and permanently confined thereto, substantially as specified.

3. A photographic sensitive plate having a mount permanently secured thereto and forming at the edge of the plate flanges projecting both forwardly and rearwardly therefrom, substantially as specified.

4. A photographic sensitive plate having a mount permanently secured thereto and forming flanges projecting beyond the plate both in front and rear and an attaching device secured to said mount and projecting therefrom to a less extent than the rear flange, substantially as specified.

5. A photographic sensitive plate having a mount permanently secured thereto and consisting of a sunken back plate with edge flange overlapping the edge of the sensitive plate, and an attaching device secured to said back plate and contained within the sunken portion of the same, substantially as specified.

708,166. AUTOMATIC PHOTOGRAPHIC APPARATUS. GEORGE H. PEYER, Cleveland, Ohio, assignor to the American Automatic Photographic Company, Cleveland, Ohio, a Corporation of Ohio. Filed Dec 13, 1901. Serial No. 86,736. (No model.)



Claim.—1. In automatic photographic apparatus, the combination of a photographic magazine, a motor, means for energizing said motor, means for feeding a plate from said magazine, such energizing and plate-feeding means being operatively connected whereby a plate may be fed simultaneously with the energizing of the motor.

2. In automatic photographic apparatus, the combination of a plate-magazine, a motor, an operating-lever for energizing said motor, and a reciprocatory slide positively connected with said lever for feeding a plate from said magazine.

3. In automatic photographic apparatus, the combination of a plate-magazine, a motor, an operating-lever for energizing said motor, and means for feeding a plate from said magazine and positively connected with said lever.

4. In automatic photographic apparatus, the combination of a motor, a plate-magazine, an operating-lever for energizing said motor, means for feeding a plate from such magazine and controlled by the operation of said lever, and plate exposing and finishing means controlled by such lever.

5. In automatic photographic apparatus, the combination of a motor, a plate-magazine, an operating-lever for energizing said motor, means for feeding a plate from said magazine and controlled by the operation of said lever, and plate exposing and finishing means controlled by said lever and operated by said motor.

6. In automatic photographic apparatus, the combination of a motor, a plate-magazine, an operating-lever for energizing said motor, means for feeding a plate from said magazine and controlled by the operation of said lever, plate exposing and finishing means operated by said motor, and an electric circuit containing means for controlling the action of the motor, such circuit being controlled by said operating-lever.

7. In automatic photographic apparatus, the combination of a motor, a plate-magazine, an operating-lever for energizing said motor, means for feeding a plate from said magazine, plate exposing and finishing means operated by said motor an electric circuit containing a magnet, means for interrupting the action of such motor controlled by said magnet, and circuit-closing means operated by said operating-lever.

8. In automatic photographic apparatus, the combination of a motor, a plate-magazine, an operating-lever for energizing said motor, means for feeding a plate from said magazine, a shutter for exposing a plate and means for operating same, plate-finishing means operated by said motor, an electric circuit containing means for controlling the opening of said shutter, means for closing the latter, means for interrupting the action of the motor, means in said circuit for controlling such interrupting means, such circuit being controlled by said operating-lever, and means operated by the motor for actuating the finishing means subsequently to the opening and closing of the shutter.

9. In automatic photographic apparatus, the combination of a motor, a plate-magazine, an operating-lever for energizing said motor, means for feeding a plate from said magazine and operated by said lever, a shutter for exposing a plate and means for opening same, an operating-wheel connected with said motor, plate-finishing means, an electric circuit containing a magnet, an armature controlled by said magnet, means for interrupting said motor's action controlled by said armature, said operating-wheel adapted to actuate the finishing means and close the shutter, and said lever adapted to control said circuit.

10. In automatic photographic apparatus, the combination of a series of receptacles for holding material for finishing a photographic plate, an operating-wheel, and means for transferring a plate from one receptacle to another, said wheel provided with means for successively operating such transferring means.

11. In automatic photographic apparatus, the combination with a series of receptacles for holding materials for finishing a photographic plate, each said receptacle provided with a movable carrier for receiving a plate, such carrier adapted to transfer such plate from its respective receptacle to the next carrier, of means for successively actuating such carriers.

12. In automatic photographic apparatus, the combination with a series of receptacles for holding material for finishing a photographic plate, each such receptacle provided with a tilting carrier adapted to transfer a plate from its respective receptacle to the next, of means for successively tilting said carriers.

13. In automatic photographic apparatus, the combination of a series of receptacles for holding material for finishing a photographic plate, each such receptacle provided with a carrier for receiving and holding such plate, such carrier being movable and adapted to transfer such plate from its respective receptacle to another carrier.

14. In automatic photographic apparatus, the combination of a series of receptacles for holding material for finishing a photographic plate, each such receptacle provided with a carrier depending therein for receiving and holding such plate, such carrier adapted to transfer a plate from its respective receptacle to another carrier.

15. In automatic photographic apparatus, the combination of a series of tanks, a series of movable carriers, a carrier being located in each tank, and an operating wheel and motor therefor, said wheel provided with means for actuating said carriers successively.

16. In automatic photographic apparatus, the combination of a se-

ries of tanks, a series of movable carriers, a carrier being located in each tank, a series of lever systems connected with said carriers and adapted to actuate same, and an operating wheel and motor therefor, said wheel provided with means for actuating said lever systems successively.

17. In automatic photographic apparatus, the combination of a series of tanks, a series of movable carriers, a carrier being located in each tank, a series of lever systems connected with said carriers and adapted to actuate same, and an operating wheel and motor therefor, said wheel provided with a series of projecting studs, each stud adapted to engage and actuate one of said lever systems.

18. In automatic photographic apparatus, the combination of a series of juxtaposed tanks, a series of tiltable carriers, a carrier being located in each tank, a series of lever systems connected with said carriers and adapted to tilt same, said systems including a row of alined trip members; an operating wheel and motor therefor, said wheel being provided with a series of projecting studs having a path of movement intersecting said trip members, whereby the latter may be engaged and said carriers tilted successively.

19. In automatic photographic apparatus, the combination of a tank, a plate-carrier mounted upon a support permanently located relatively to said tank so as to be movable into and out of the latter, and means for automatically actuating such carrier.

20. In automatic photographic apparatus, a discharging-duct of tubular form having its receiving-end opening located in the lateral wall of the upper portion thereof.

21. In automatic photographic apparatus, a discharging-duct consisting of a tube having a receiving-opening in the lateral wall of the upper tube portion and a lower portion removed from and projecting transversely of the tube-bore.

22. In automatic photographic apparatus, a discharging-duct consisting of a tube having a receiving-opening at its upper end, a discharge-opening at its lower end, and a lower portion removed from said opening and projecting transversely of the tube-bore.

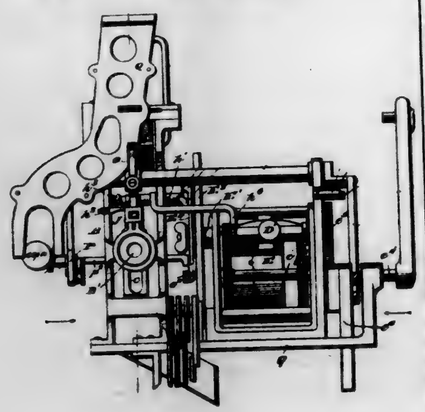
23. In automatic photographic apparatus, the combination of a bath for developing a photographic plate, means for removing said plate from said bath, and an operating-wheel provided with an angularly-adjustable arm for actuating said removing means, said wheel being provided with marks indicating angular intervals of wheel travel, said arm provided with an indicating-pointer located in the vicinity of the marked portion of said wheel.

24. In automatic photographic apparatus, the combination of a camera, a shutter therefor, and means for operating same, plate-feeding means and means for operating same, plate finishing means, a motor, and means actuated by the shutter-operating means for controlling the operation thereof, said finishing means operated by said motor.

25. In automatic photographic apparatus, the combination of a camera, a shutter therefor and means for operating same, plate feeding and finishing means, a motor, means actuated by the shutter-operating means for controlling the operation of the motor, said finishing means operated by said motor, said shutter-operating means controlled by the energizing means.

708,187. COIN-CONTROLLED PHOTOGRAPHIC APPARATUS.

GEORGE H. PIPER, Cleveland, Ohio, assignor to the American Automatic Photographic Company, Cleveland, Ohio, a Corporation of Ohio. Filed Mar. 3, 1902. Serial No. 97,206. (No model.)



Claim.—1. In coin-controlled, automatic photographic apparatus, the combination of a motor, a coin-duct, an operating-lever connected with said motor, and an electrical-circuit-containing means for controlling the operation of said motor, and two pairs of electrical contacts for opening and closing such circuit, a member of one pair being located in the coin-path of said duct and a member of the other being located in the lever-path.

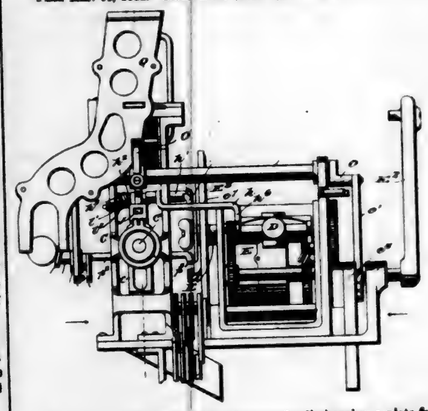
2. In coin-controlled, automatic photographic apparatus, the combination of a motor, a coin-duct, an operating-lever for energizing such motor, and an electrical-circuit-containing means for controlling the operation of said motor, and two pairs of contacts for opening and closing said circuit, a member of one pair being located in the coin-path of said duct, and a member of the other being located in the lever-path at the end of its energizing stroke.

3. In a coin-controlled automatic photographic apparatus, the combination of a motor, a coin-duct, means for controlling the operation of said motor, including a pair of electrical contacts one of which is movable and adapted while in contact with the other to hold same in the coin-path of said duct, and means for actuating said movable contact to disengage the other contact, whereby the latter may be removed from the coin-path.

4. In coin-controlled automatic photographic apparatus, the combination of a motor, a coin-duct, an operating-lever connected with said motor; and an electrical circuit including means for controlling the operation of said motor, three pairs of electrical contacts for opening and closing such circuit, a member of one pair being located in the coin-path of said duct, a member of a second pair being located in the lever-path, and a member of the third pair being capable of being manually operated.

708,168. SHUTTER FOR AUTOMATIC PHOTOGRAPHIC APPARATUS.

GEORGE H. PIPER, Cleveland, Ohio, assignor to American Automatic Photographic Company, Cleveland, Ohio, a Corporation of Ohio. Filed Mar. 11, 1902. Serial No. 97,735. (No model.)



Claim.—1. The combination of means for discharging a plate from a focal plane, a lens-controlling shutter, and an operating-wheel embodying means for operating said discharging means and for closing said shutter, said operating means and closing means being relatively fixed.

2. The combination of means for discharging a plate from a focal plane, a lens-controlling shutter, and an operating-wheel provided with relatively fixed lips respectively adapted to operate said discharging means and to close said shutter.

3. The combination of a shutter, a motor-operated wheel, and an angularly-adjustable arm on said wheel for closing said shutter.

4. The combination of a shutter, a motor-operated wheel, and an angularly-adjustable arm on said wheel for closing said shutter, said wheel being provided with a series of indicating-marks, whereby the angularity of said arms and hence the time of exposure may be indicated.

5. The combination of means for discharging a plate from a focal plane, a lens-controlling shutter, and a motor-operated angularly-adjustable arm, one end of said arm being adapted to close said shutter and the other to engage and operate said discharging means.

6. The combination of an operating-wheel and motor therefor, a shutter, a spring-actuated shaft connected with and adapted to open said shutter, a sleeve, a step-arm for controlling the operation of said wheel mounted upon said sleeve, the latter forming a bearing for said shaft, said sleeve provided with means for engaging said shaft when moved in one direction and for disengaging same when moved in the opposite direction, said wheel provided with means for engaging said shaft whereby said shutter may be closed independently of said stop-arm.

7. The combination of an electrical circuit containing a magnet, armature and means for opening and closing the circuit, a spring-actuated arm, a shutter connected with such arm, said armature adapted to hold such shutter in a closed position against the action of the spring, whereby upon the movement of the armature said spring may be caused to actuate the shutter to open.

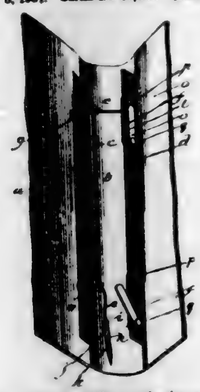
8. The combination of an electrical circuit containing a magnet, armature and means for opening and closing the circuit, a motor, a spring-actuated arm, a shutter and motor-controlling means connected with such arm, said armature adapted to hold such shutter in a closed position against the action of the spring, and means connected with the motor for closing such shutter.

9. In automatic photographic apparatus including a motor, the combination with means for controlling the operation of the motor and embodying an exterior movable element, of a light-circuit, said movable element adapted to control said light-circuit.

10. In automatic photograph apparatus including a motor, the combination with an electric-light circuit, of electrical means for controlling the operation of said motor, and embodying an exterior movable element which is provided with means for controlling the electrical circuit in said motor-controlling means, said movable element being adapted to control said light-circuit.

708,169. PERIODICAL-FILE.

CORYDON L. PRIBBLE, Evanston Ill. Filed July 5, 1901. Serial No. 67,147. (No model.)



Claim.—1. In a binding or filing mechanism a needle with the eye extending longitudinally from the head to a notched opening in the side, said opening forming a recessed shoulder to retain the knotted end of the binding-cord, in combination with the cord *c*, stays *c* and *d* and locking device *f*, substantially as described.

2. In a binding or filing mechanism a needle having adjacent to the eye an inwardly-diminishing slot in the side, said slot being adapted to have the binding-cord drawn securely therein, in combination with the locking device *f*, cord *c* and stays *c* and *d*, substantially as described.

3. In a binding or filing mechanism the locking device *f*, consisting of a fixed inner plate *l* having an aperture *m* for the insertion of the needle, a pocket *n* to inclose the needle, and a movable cap *o* to confine and conceal the needle, in combination with the stays *c* and *d*, and the needle *h* and cord *c*, said needle being adapted to the adjustment of the cord immovably thereon, substantially as described.

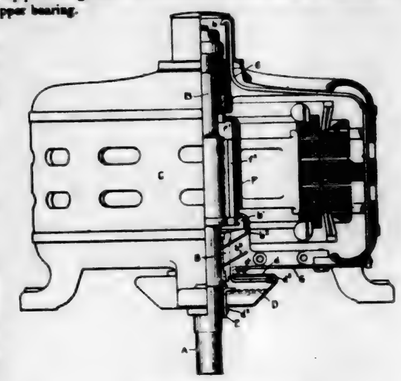
4. In a binding or filing mechanism the combination of the eyelets *r s*, adapted to be inserted through the folds of a signature and engage the binding-cord, the cord *c* and stays *c* and *d*, with the needle *h* and lock *f*, said needle and lock cooperating to secure to the stay *d* the free end of the binding-cord, substantially as described.

708,170. LUBRICATING DEVICE.

HENRY G. REISS, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Jan. 23, 1901. Serial No. 44,398. (No model.)

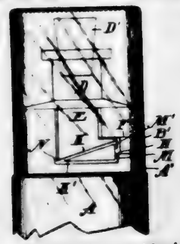
Claim.—In a dynamo-electric machine, the combination, with the rotatable member thereof mounted on an upright shaft, of upper and lower bearings for said shaft, there being a passage or duct in said member joining said bearings, an oil-cup for the upper bearing, a centrifugally-operated oiling device secured to the rotating member beneath the lower bearing and arranged to receive the oil flowing therefrom, and a trans-

for-pipe leading from said device out around the rotating member to the upper bearing.



708,171. NON-REFILLABLE BOTTLE.

HORACE B. REUBELT Franklin, Tenn. Filed Jan. 3, 1902. Serial No. 88,265. (No model.)



Claim.—1. A non-refillable bottle, comprising in combination with the body portion of the bottle, having an annular shoulder on its outer wall, a recess in the outer wall, said recess having a laterally-projecting portion, a spring having its ends bent at right angles and seated within said recess, a cap having a flange upon its inner wall, said flange adapted to enter the recess in the outer wall of the bottle, and to be turned with the cap so as to enter said laterally-projecting portion of the recess, and to be held therein, by the end of said spring, the cap adapted to rest upon said annular shoulder, as set forth.

2. A non-refillable bottle, comprising in combination with the bottle, having an annular flange in its outer wall, below the neck portion of the bottle, a recess E and a V-shaped recess N at the bottom of the latter, a laterally-projecting recessed portion F extending horizontally at a location near the bottom of the recess E, a shoulder H intermediate said recessed portion F and recess E, a spring bent upon itself and fastened in said V-shaped recess, the ends of said spring being bent at right angles, a frangible cap, a segment-flange on the inner wall of said cap, adapted to be pushed down through the recess E, against the arm of the spring, and to be turned into said recessed portion F, and held therein by an arm of said spring, as set forth.

708,172. SPINNING-MACHINE FOR CHEWING-TOBACCO.

WILLIAM SCHERTIGER, Aalborg, Denmark. Filed Apr. 21, 1902. Serial No. 104,088. (No model.)

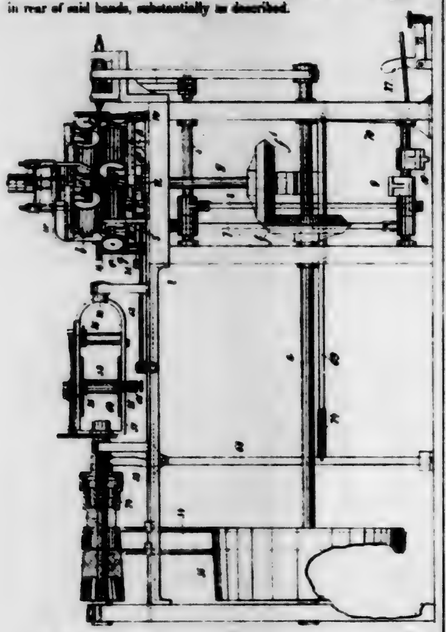
Claim.—1. In a machine for spinning chewing-tobacco, a twisting-needle with means for continuously rotating the same, a pair of superposed endless bands in proximity to the point of said needle with means for operating them, and a winding-drum in rear of said belts, substantially as described.

2. In combination, an initial twisting-needle, a pair of endless bands arranged at an angle to each other, the said needle projecting into proximity to the crossing-point of said bands, means for driving said bands, and a winding-drum in rear of said bands, substantially as described.

3. In combination, an initial twisting-needle, a pair of endless bands arranged at an inclination to each other and in proximity to the point of said needle, means for varying the inclination of said bands with relation to each other, and a winding-drum in rear of said bands, substantially as described.

4. In combination, an initial twisting-needle, upper and lower bear-

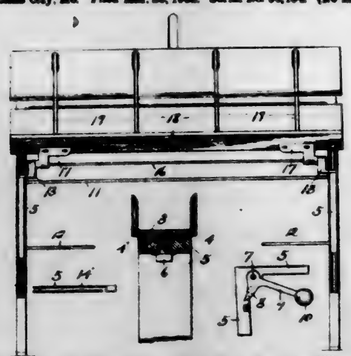
ing-plates, means for adjusting said plates in a circular manner, a pair of rollers carried by each plate, an endless band carried by each pair of rollers, means for driving one of the rollers of each pair, and winding means in rear of said bands, substantially as described.



3. In combination, a vertical shaft, with means for operating it, upper and lower plates capable of oscillating on an axis coincident with said shaft, a pair of rollers journaled in each plate, endless bands carried by said rollers, a gear-wheel carried by the vertical shaft, small gears meshing therewith, vertical shafts extending upward from said small gears into proximity to the rollers, worms on said shafts, worm-wheels connected with the rollers engaging said worms, means for oscillating said plates to vary the inclination of the bands, means for feeding tobacco between the bands on one side and coiling or winding means on the other, substantially as described.

4. In combination, an initial twisting-needle, a pair of endless bands arranged at an inclination to each other with means for operating them, a winding-drum in rear of said bands and friction means for driving said winding means, substantially as described.

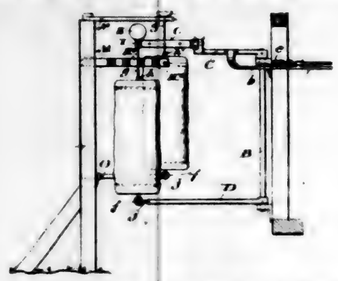
708,173. ADJUSTABLE BOTTLE-REST. RUDOLPH SCHMIDT, Kansas City, Mo. Filed Mar. 20, 1902. Serial No. 99,154. (No model.)



Claim.—1. The combination with the front legs of a filling-tank, of a pair of ratchets secured to said legs respectively, a bracket mounted slidably on each of said ratchets, a pawl secured to each bracket in position to engage the adjacent ratch, means for holding the pawls yieldingly against the ratchets, a bearing mounted slidably on the top of each bracket, a rod connecting said bearings, and an angular bottle-rest supported indirectly by said rod; substantially as described.

2. The combination, with the front legs of a filling-tank, of a pair of ratchets secured to said legs respectively, a bracket mounted slidably on each of said ratchets, the base of each bracket having a vertical slot therein, a cap-screw passing through each of said slots and entering one of said ratchets, a pawl secured to each bracket in position to engage the adjacent ratch, means for holding said pawls yieldingly against the ratchets, a bearing mounted slidably on the top of each bracket, a rod connecting said bearings, and an angular bottle-rest supported indirectly by said rod; substantially as described.

708,174. POSTAL CAR AND STATION APPLIANCE. LOUIS SCHLENDER, Theresa, Wis., assignor of one-half to John Gerlach, Theresa, Wis. Filed June 9, 1902. Serial No. 110,723. (No model.)



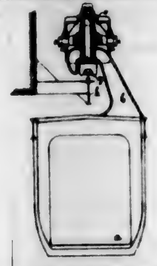
Claim.—1. A postal-car appliance comprising a lever-controlled swing-frame adjacent to a side doorway of the car, a latch on the lever, keepers for the latch arranged with respect to holding the swing-frame in different positions of adjustment, means in connection with said swing-frame for releasable suspension of a mail-bag, as well as for catching and detaching such a bag from suspending devices at a station, and other means at the station for catching and holding the former bag.

2. A postal-car appliance comprising a swing-frame adjacent to a side doorway of the car, a pivotally-adjustable upper outer bar in connection with the swing-frame, a yielding catch extending in one direction from the outer end of the bar for the engagement of a flexible device connecting one end of a mail-bag with a step designed to overlie the catch, a swivel-hook in connection with the outer end of a lower swing-frame arm in alinement to said catch to engage with a ring in connection with the other end of the mail-bag and other yielding catches alined on said bar to extend therefrom in the direction opposite the former catch to be one or the other thereof engaged by a stop-attached flexible device in connection with a mail-bag suspended from a station-frame passed by said car.

3. A railway-postal-station frame having an upper horizontal beam thereof provided with a pair of bars each adjustable on vertical pivots to stand at a right angle to the frame, yielding catches alined on sides of the bars, those of one bar being extended in an opposite direction to those of the other bar, a forked-end arm in connection with a vertical pivot on an upper frame-timber the plane of this pivot being intermediate of those aforesaid, another arm adjustable on a horizontal pivot in connection with a lower frame-timber to stand with the other arm at a right angle to said frame, and a swivel-hook in connection with the free end of the lower arm; the catches aforesaid being singly for automatic engagement of a flexible device connecting one end of a mail-bag with a catch-overlying stop, the bag being normally suspended from a swung-out postal-car appliance provided with other yielding catches for engagement of a similar flexible device engageable with the forked-end frame-arm and connecting an overlying stop with a mail-bag having a lower ring engaged by the swivel-hook of the other frame-arm.

708,175. SUSPENDED RAILWAY-VEHICLE. WILHELM SCHMITZ, Elberfeld, Germany, assignor to the Continentale Gesellschaft für Elektrische Unternehmungen, Nuremberg, Germany. Filed Nov. 5, 1901. Serial No. 81,228. (No model.)

Claim.—1. In monorail elevated railways with suspended vehicles a connection between the wheel-trucks and the vehicle-box consisting of a universal joint above the rails composed of a vertical axis and a horizontal axis parallel to the truck-wheel axles in combination with an arrangement of the masses and the area exposed to air resistance, of the trucks and the vehicle-box so as to have their lines of gravity passing through the center of the rail-head, as and for the purpose set forth.



2. In monorail elevated railways with suspended vehicles a connection between the wheel-trucks and the vehicle-box consisting of a universal joint above the rails composed of a vertical axis and a horizontal axis parallel to the truck-wheel axles in combination with an arrangement of the masses and the area exposed to air resistance, of the trucks and the vehicle-box so as to have their lines of gravity passing through the center of the rail-head, and a safety-catch connected to the truck-frame, embracing the rail-carrier, as and for the purpose set forth.

3. In monorail elevated railways a vehicle provided with universal-joint connections for supporting said vehicle at two or more points above the rail, the arrangement being such that the vehicle will adapt itself for variable curves and gradients, substantially as described.

4. In monorail elevated railways a vehicle provided with universal-joint connections for supporting said vehicle at two or more points above the rail; in combination with one or more safety-catches located below the rail-support, substantially as described.

708,176. TOOL-HOLDER. CHARLES T. SHAFER, Springfield, Ohio, assignor to the Western Manufacturing Company, Springfield, Ohio, a Corporation of Ohio. Filed Apr. 11, 1901. Serial No. 55,289. (No model.)

Claim.—1. A tool-holder having a lateral recess or seat in its head, terminating at the bottom in a shoulder or flange, undercut to receive and prevent lateral movement of the lower edge of the tool, in combination with a cap supported on said head, extending over the top of said recess or seat, and provided with a depending flange to engage the outer face of the tool at its upper edge, and means for adjustably securing said cap on said head, said means comprising engaging surfaces on the head and cap, one of which is inclined to the face of the seat or recess, whereby, when the cap is moved longitudinally on the head, its depending flange will be pressed against the upper edge of the tool, substantially as described.

2. A tool-holder having in one side of its head a lateral recess or seat, terminating at the bottom in a shoulder or flange, undercut to receive and prevent lateral movement of the lower edge of the tool, the opposite side of the head being provided with a bearing-surface inclined to the plane of the recess or seat in the first-mentioned side, a cap adjustably supported on said head and extending beyond both sides thereof, being provided on the recessed side with a depending flange to engage the outer face of the tool at its upper edge, and having on the opposite side of the head a depending flange to engage the inclined bearing-surface of said side, and means for securing said cap in position on the head after adjustment, substantially as described.

3. A tool-holder having in one side of its head a lateral recess or seat, terminating at the bottom in a shoulder or flange, undercut to receive and prevent lateral movement of the lower edge of the tool, the opposite side of the head being provided with a bearing-surface inclined to the plane of the recess or seat in the first-mentioned side, a cap adjustably supported on said head and extending beyond both sides thereof, being provided on the recessed side with a depending flange to engage the outer face of the tool at its upper edge, and having on the opposite side of the head a depending flange to engage the inclined bearing-surface of said side, and means for securing said cap in position on the head after adjustment, said means comprising a slot in the cap parallel with the inclined bearing-surface, and a stamping-screw passing through said slot into the head, substantially as described.

4. A tool-holder comprising a head and shank, both having formed in them a continuous lateral recess or seat, terminating at the bottom in an undercut shoulder or flange to receive and prevent lateral movement of the lower edge of the tool, in combination with a clamping-cap mounted on the head and adapted to grip the upper edge of the tool, and a flat wearing-plate, of harder material than the shank, permanently secured on the top of the shank and extending laterally beyond the same over the top of the recess or seat therein immediately above the tool, substantially as described.

708,177. BORING-MACHINE. WILLIS S. SHERMAN, Milwaukee, Wis. Filed Jan. 6, 1902. Serial No. 88,563. (No model.)

Claim.—1. In a boring-machine, rotatably-mounted drill-heads disposed opposite to each other and arranged to be rotated together, each head carrying a drilling-tool extending beyond the outer rim thereof.

2. In a boring-machine, rotatably-mounted drill-heads disposed opposite to each other and arranged to be rotated together, and each head carrying a plurality of drilling-tools extending beyond the outer rim thereof.

3. In a boring-machine the combination with rotatably-mounted drill-heads disposed opposite to each other and arranged to rotate together, and each head carrying a drilling-tool, extending beyond the outer rim thereof, of means for adjusting one of the heads so as to bring its tool out of transverse line with the tool of the other head.

4. In a boring-machine, the combination with rotatably-mounted drill-heads disposed opposite to each other, and arranged to rotate together, and each head carrying a plurality of drilling-tools extending beyond the outer rim thereof, of means for adjusting one of the heads so as to bring its tools out of transverse line with the tools of the other head.

5. In a boring-machine, the combination with rotatably-mounted drill-heads disposed opposite to each other, and arranged to rotate together, each head carrying a drilling-tool extending beyond the outer rim thereof, of means for adjusting one of the heads closer to or farther away from the other head.

6. In a boring-machine, pivotally and rotatably mounted drill-heads disposed opposite to each other, and arranged to be rotated together, each head carrying a drilling-tool extending beyond the outer rim thereof.

7. In a boring-machine, the combination of pivotally and rotatably mounted drill-heads disposed opposite to each other, and arranged to rotate together, each head carrying a drilling-tool extending beyond the outer rim thereof, of means for adjusting one of said heads closer to or farther away from the other head.

8. In a boring-machine, the combination of rotatably-mounted drill-heads disposed opposite to each other, and one of said heads provided with a plurality of openings, a pin secured to one of the heads and adapted to extend into one of the openings of the other head, in accordance with the extent to which said head is rotatably adjusted, and a drilling-tool carried by each head and extending beyond the outer rim thereof.

9. In a boring-machine, the combination of rotatably-mounted drill-heads disposed opposite to each other, and one of said heads provided with a plurality of openings, pins secured to one of the heads and adapted to extend into any of the openings of the other head, in accordance with the rotatable adjustment of said head, and a drilling-tool carried by each head and extending beyond the outer rim thereof.

10. In a boring-machine, the combination of rotatably-mounted drill-heads disposed opposite to each other and one of said heads provided with a plurality of openings, a pin secured to one of the heads and adapted to extend freely into one of the openings of the other head, in accordance with the extent to which said head is rotatably adjusted, means for adjusting the latter head closer to or farther away from the other head, and

a drilling-tool carried by each head and extending beyond the outer rim thereof.

11. In a boring-machine, the combination of rotatably-mounted drill-heads disposed opposite to each other, said one of said heads provided with a plurality of openings, a pin adjustably secured to one of the heads and adapted to extend into one of the openings of the other head, in accordance with the extent to which said head is rotatably adjusted, and a drilling-tool carried by each head and extending beyond the outer rim thereof.

12. In a boring-machine, the combination of standards or bearings, a shaft supported therein, arms pivotally mounted on said shaft, drill-heads rotatably carried at the forward ends of the arms, means for causing said heads to rotate together, and a drilling-tool carried by each head and extending beyond the outer rim thereof.

13. In a boring-machine, the combination of standards or bearings, one of said standards or bearings being adjustably secured so as to be brought closer to or farther away from the other standard or bearing, a shaft supported in the standards or bearings, arms extending from the shaft, drill-heads rotatably carried at the opposite ends of said arms, means for causing the heads to rotate together, and a drilling-tool carried by each head and extending beyond the outer rim thereof.

14. In a boring-machine, the combination of standards or bearings, the upper ends thereof being bifurcated, and the furcate arms provided at their extremities with boxes, sleeves arranged within said boxes, a shaft supported in the sleeves, arms provided at their ends with eyes surrounding the sleeves between the boxes of the furcate arms of the standards, drill-heads rotatably carried at the opposite ends of the arms, means for causing said heads to rotate together, and a drilling-tool carried by each head and extending beyond the outer rim thereof.

15. In a boring-machine, the combination of a bed-piece or support, standards or bearings extending therefrom, the upper ends of said standards being bifurcated, and the furcate arms provided at their extremities with boxes, and one of said standards being adjustably secured to the bed-piece or support so as to be brought closer to or farther away from the other standard or bearing, sleeves arranged within the boxes, a shaft supported in the sleeves, means for securing the sleeves and boxes together, arms provided at their ends with eyes surrounding the sleeves between the boxes of the furcate arms of the standards, drill-heads carried at the opposite ends of the arms, means for causing said heads to rotate together, and a drilling-tool carried by each head and extending beyond the outer rim thereof.

16. In a boring-machine, the combination of standards or bearings, a drive-shaft mounted in the upper ends thereof, means for rotating the shaft, arms pivotally mounted on said shaft, the opposite ends of the arms provided with boxes, driven shafts mounted in said boxes, drill-heads disposed opposite to each other and arranged to rotate together, a drilling-tool carried by each head and extending beyond the outer rim thereof, a gearing between said drilling-tool and each driven shaft, and connections between the driven shafts and the drive shaft, whereby the rotation of the latter is imparted to the former.

17. In a boring-machine, the combination of standards or bearings, a drive-shaft mounted in the upper ends thereof, means for rotating the shaft, pulleys mounted on the shaft, one of said pulleys being adjustable thereon, arms pivotally mounted on the shaft, the opposite ends of said arms provided with boxes, drill-heads provided with outwardly-extending journals which pass through said boxes of the arms, one of said drill-heads being adjustable toward and from the other, driven shafts mounted in said journals, a drilling-tool carried by each drill-head and extending beyond the outer rim thereof, a gearing between each drilling-tool and each driven shaft, pulleys mounted on the driven shafts, and endless belts connecting said pulleys with the pulleys of the drive-shaft.

18. In a boring-machine, the combination of a bed-piece or support, standards or bearings extending therefrom, the upper ends of said standards being bifurcated, and the furcate arms provided at their extremities with boxes, and one of said standards being adjustably secured to the bed-piece or support so as to be brought closer to or farther away from the other standard, sleeves arranged within the boxes, means for securing the boxes to the sleeves, a drive-shaft supported in the sleeves, means for rotating said shaft, pulleys mounted on the drive shaft, one of said pulleys being adjustable thereon, arms provided at their ends with eyes surrounding the sleeves between the boxes of the furcate arms, drill-heads disposed opposite to each other and provided with outwardly-extending tubular journals, a drilling-tool carried by each head and extending beyond the outer rim thereof, driven shafts mounted in the said journals, a gearing between each of said shafts and the drilling-tool of the head rotating thereto, a pulley mounted on each of said shafts, endless belts connecting said pulleys with the pulleys of the drive-shaft, and means for adjusting one of the drill-heads toward or from the other.

19. In a boring-machine, the combination of rotatably-mounted drill-heads disposed opposite to each other and arranged to be rotated together, rotatable shafts each carrying at its inner end a beveled gear, and a drilling-tool carried by each drill-head and provided with a beveled pinion meshing with the beveled gear of each shaft the outer end of said tool projecting beyond the outer rim of the head.

20. In a boring-machine, the combination of rotatably-mounted drill-heads disposed opposite to each other and arranged to be rotated together, each head provided with an outwardly-extending journal, a rotatable shaft in each journal, each shaft carrying at its inner end a beveled gear, and a drilling-tool carried by each drill-head and provided with a beveled pinion meshing with the beveled gear of each shaft the outer end of said tool projecting beyond the outer rim of the head.

21. In a boring-machine, the combination of rotatable carriers, a drilling-tool carried by each carrier, the axes of the tools lying in the plane of rotation of the carriers, and means for adjusting the distance apart laterally of said carriers.

22. In a boring-machine, the combination of rotatable carriers, a drilling-tool carried by each carrier, the axes of the tools lying in the plane of rotation of the carriers, means for adjusting the distance apart laterally of said carriers, and means for adjusting one of the carriers so as to advance its tool with relation to the tool of the other carrier.

708,178. METHOD OF PRODUCING VARNISH-OILS. WILLIAM A. SMITH, Cleveland, Ohio. Filed Oct. 23, 1901. Serial No. 79,632. (No specimens.)

Claim.—1. A method of producing a substitute for linseed-oil, consisting of: first, boiling resin in concentrated sulfuric acid until the mixture ceases to foam, by which sulfonic acids of the constituents of resin are formed, whose lead salts are not of a curdy nature, and secondly, thinning down with a refined illuminating-oil.

2. A method of producing a substitute for linseed-oil, consisting of: first, boiling resin in sulfuric acid until the mixture ceases to foam, by which sulfonic acids of the constituents of resin are formed, whose lead salts are not of a curdy nature, and secondly, thinning down with refined second-grade illuminating-oil.

3. A composition of matter, consisting of substantially one-half refined petroleum-oil, and one-half abietic sulfonic acid and the sulfonic acids of other constituents of resin.

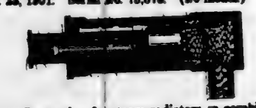
4. A substitute for linseed-oil, consisting of a mixture of substantially equal parts of refined petroleum oil and the sulfonic derivatives of the constituents of resin.

5. A substitute for linseed-oil, consisting of a mixture of substantially one-half abietic sulfonic acid and other chemical products formed when resin is boiled in sulfuric acid, and one-half some lighter oil.

6. A substitute for linseed-oil, consisting of a mixture of substantially equal parts of refined second-grade illuminating-oil, and the chemical products formed when resin is boiled in sulfuric acid.

7. A substitute for linseed-oil, which has the same gravity as linseed-oil, consisting of a mixture of substantially equal parts of refined second-grade illuminating-oil, and the chemical products formed when resin is boiled in concentrated sulfuric acid.

708,179. AUTOMATIC VALVE. HENRY R. STAGER, Chicago, Ill. Filed Aug. 23, 1901. Serial No. 73,073. (No model.)

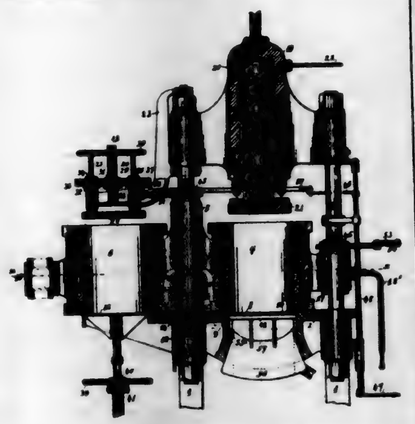


Claim.—1. In a valve for steam-radiators, in combination, an outer shell or casing having an inlet-opening and an air-escape opening; a tubular body portion formed integral with one of the ends of said shell or casing, projecting into the interior thereof and being provided at its inner end with an opening; an air-bell within said outer casing, having a projection adapted to close the opening in said body portion; and a pencil expansible by heat, mounted in said body portion and adapted to close the opening therein.

2. In a valve for steam-radiators, in combination, a bottom cap provided with a screw-threaded plug for connecting said valve with a radiator, said plug having an opening extending therethrough and communicating with the interior of the bottom cap; a casing-shell secured to said bottom cap; an air-bell in said bottom cap and said casing-shell, the bottom of said air-bell being normally below the mouth of the opening through said plug; a projection on said air-bell; a cap secured to the upper end of said casing-shell; a tubular body portion supported within said casing-shell by said cap, said body portion having an opening in its lower end adapted to be closed by the projection on said air-bell; a pencil expansible by heat, also adapted to close said opening; a plug in said tubular body portion, for supporting said pencil, said plug having a screw-thread engagement with the body portion; and a closure for the upper end of said tubular body portion.

3. In a valve for steam-radiators, in combination, a bottom cap provided with a screw-threaded plug for connecting said valve with a radiator, said plug having an opening extending therethrough and communicating with the interior of the bottom cap; a casing-shell secured to said bottom cap; an air-bell in said bottom cap and said casing-shell, the bottom of said air-bell being normally below the mouth of the opening through said plug; a projection on said air-bell; a cap having a screw-thread engagement with the upper end of said casing-shell; a tubular body portion formed integral with said cap and extending into said casing-shell, said body portion having an opening in its lower end adapted to be closed by the projection on said air-bell; a raised rim around the opening in said body portion; a pencil expansible by heat, adapted when expanded to contact said raised rim to close said opening; a plug in said tubular body portion, for supporting said pencil, said plug having a screw-thread engagement with the body portion; and a closure for the upper end of said tubular body portion.

708,180. HYDRAULIC PRESS FOR THICK FLUID SUBSTANCES. GOTTFRIED VON SÜSKIND, St. Georgen, Switzerland. Filed Feb. 24, 1902. Serial No. 96,467. (No model.)



Claim.—1. In a hydraulic press for thick fluid masses, rotatable receptacles, a divided mold in communication with said receptacles, means for lifting the said rotatable receptacles out of a recess in the table, mechanism for adjustably securing the receptacles to their support, and means for heating the mold and the substances under pressure.

2. In a hydraulic press for thick fluid masses, rotatable receptacles, a plurally-divided mold placed in the table and secured in position by the receptacles and screws, a hydraulic pressure device concentric to the axis of rotation of the receptacles and adapted to lift the rotatable receptacles out of the recess in the table, means for adjustably securing the receptacles to their support, a perforated heating-body having a system of passages and placed beneath the mold for heating the same and the substances under pressure.

3. In a hydraulic press for thick fluid masses, in combination the posts 3 and 4, the center piece 5 the receptacles 6 and 7, the mold 8, the funnel 56, the plate 42, the grating 57, the steam-passages 59 and 60, the inlet-pipes 63 and 64 the outlets 65 and 66, mechanism for raising said receptacles 8 and mechanism for adjustably securing the receptacles to their support.

708,181. SEPARABLE BUTTON OR STUD. JOHN L. VREDENBURGH, Austin, Tex. Filed June 11, 1902. Serial No. 111,177. (No model.)

Claim.—1. In combination in a separable button, a base provided with a stem, a locking projection thereon and a head provided with a plate having an opening therein to permit of the passage of the stem and projection, said parts being adapted to be turned to couple the head and stem, and oppositely-disposed lugs struck up from the plate designed to coact with said projection to prevent the relative rotation of the parts when in coupled position.

2. In a separable button or stud of the type described, a back or base member, a stem extending therefrom, a locking member projecting laterally from the stem having two radial locking edges, a head, a plate carried thereby designed to interlock with said projection, and two interlocking lugs on said plate adapted to provide a bearing for the projection on the stem in the relative turning movement of the parts, and to confine said projection between the same when in locked position with the radial edges of said projection abutting said lugs, and a tension-spring interposed between said head and said base member, substantially as described.

3. In a separable button, a base having a stem, an arc-shaped lateral projection carried by the stem of slightly less area than a half-circle, a head, a base-plate secured thereto having an opening therethrough of the contour of the end of said stem and projection, to permit of the passage of the same when in register, and lugs arranged on the plate on diametrically opposite sides of the opening for the stem, said lugs being adapted to coact with the radial edges of the lateral projection to lock the head and stem against relative turning movement, substantially as described.

4. In a separable button, a back or base member having a stem, a flat arc-shaped projection extending laterally therefrom having radial locking edges, a head, a plate secured thereto having an opening therein conforming in contour to the end of the stem and said projection, and oppositely-arranged vertical lugs struck up from said plate on the inner face thereof, said projection being adapted to ride upon the upper edges of the lugs in the relative turning movement of the parts and to drop behind the lugs and abut thereagainst to prevent said relative turning movement, substantially as described.

5. In a separable button or the like, a head, a stud projecting axially therefrom, a base-plate for the head secured thereto and having an axial opening therein, and an arc-shaped concentric extension thereof, lugs projecting from the inner face of the plate at the juncture of the main opening and the extension of the same and extending from the wall of one to the wall of the other, a back or base member having an axial stem secured thereto provided with a central bore, a spring housed therein adapted to be compressed by said stud, and a laterally-projecting arc-shaped projection on said stem forming a locking member, substantially as described.

6. In a separable stud or the like, the combination with a back or base member having an axial stem and a projection thereon, of a head including a plate having an opening therethrough conforming in contour to the end of the stem and the projection carried thereby, and lugs struck up from the metal displaced from said opening and extended at right angles to the plate on the inner face thereof, said lugs coacting with said projection to provide a lock, and a spring for seating the projection behind said lugs, substantially as described.

708,182. CIRCUIT-INTERRUPTER. MILO S. WALKER, Chicago, Ill., assignor to the General Electric Company, a Corporation of New York. Filed Nov. 6, 1899. Serial No. 736,804. (No model.)

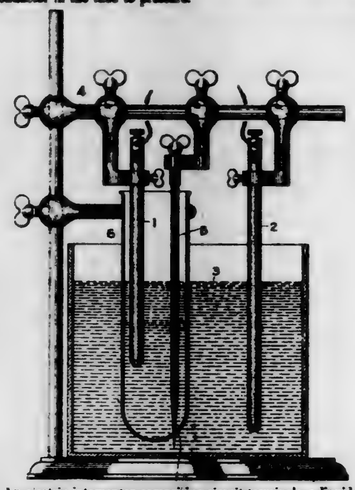
Claim.—1. The herein-described mode of maintaining electric vibration in a circuit, consisting of causing the current to traverse a narrow thread or film of conducting liquid, and maintaining at the sides of said film or thread a larger body of conducting liquid whereby the vibration is maintained by the sole action of the current.

2. An electric interrupter comprising two terminals, an electric conducting liquid between the same and in continuous open relation to the electrodes, a spot of reduced current-carrying capacity in the electric path between the electrodes, and an adjusting device for varying its carrying capacity.

3. An electric interrupter, comprising two circuit-terminals, a liquid-conductor between them and in continuous open relation to them, a perforated wall of insulating material between them, and an adjusting device for varying the size of the opening in the wall.

4. An electric interrupter comprising two circuit-terminals, one in-

closed in an insulating-tube, an opening of small cross-section establishing communication between the electrodes by a conducting liquid, means for permitting the escape of gases or vapors, and means for subjecting the liquid-conductor in the tube to pressure.

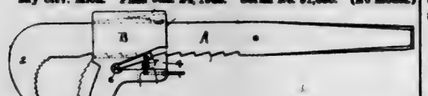


5. An electric interrupter comprising circuit-terminals, a liquid-conductor between the same, and a vertically-adjustable separating-wall of insulating material provided with a plurality of vertically-disposed openings of small cross-section.

6. An electric interrupter comprising circuit-terminals, a liquid-conductor between the same, a vertically-adjustable separating-wall of insulating material provided with a plurality of vertically-disposed openings of small cross-section, and a bed of oil above the liquid-conductor.

7. An electric interrupter comprising circuit-terminals, a liquid-conductor between the same, a separating-wall of insulating material provided with a plurality of vertically-disposed openings of small cross-section and means for including or excluding the openings from the circuit.

708,183. WRENCH. MICHAEL WALSH and JOSEPH H. ADGERS, Bay City, Mich. Filed Jan. 24, 1902. Serial No. 91,055. (No model.)



Claim.—1. In combination with the movable jaw, the wedge-shaped opening in one side thereof, said opening having a contracted lower end; the transverse part-cylindrical recess; the central vertical slot; the pivoted lever mounted therein; the upwardly-extending link; the spring on said link; the pawl having a cylindrical lower end and pivotally connected near its upper end with the upper end of the link, all arranged substantially as described and for the purposes set forth.

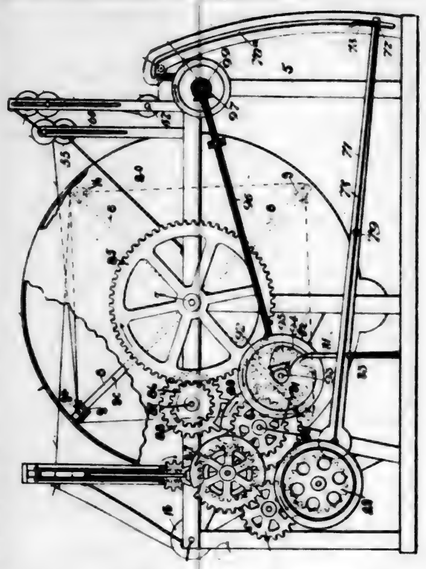
2. In a wrench of the class described, the combination of the shank having shallow depressions in its face, with the sliding jaw; and a spring mounted within said jaw and having its end adapted to slightly engage said depressions when the jaw is slid along the shank, for the purpose set forth.

3. In a wrench of the class described, the combination of a sliding jaw having a part-cylindrical transverse recess; a pawl; a link and lever for depressing said pawl; a wrench-shank having shallow depressions in its face; and a spring carried by the sliding jaw, the end of said spring being arranged to engage said depressions, all arranged for the purposes set forth.

708,184. DRYING-REEL. CHARLES D. WEAVER, McPherson, Kans., assignor to the Clark-Weaver Manufacturing Company, Greeley, Colo. Filed Apr. 1, 1902. Serial No. 100,974. (No model.)

Claim.—1. In a machine of the class described, the combination of a drying-reel, brackets adjustably mounted on the reel-arms, sprocket-wheels mounted on the brackets, and means mounted on the sprocket-wheels for automatically shifting the convolutions wound on the reel.

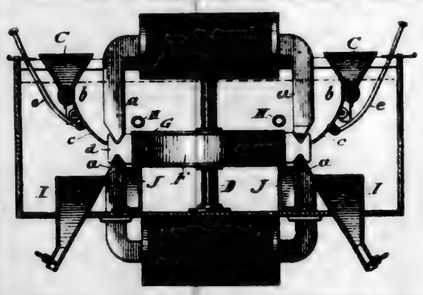
2. The combination with the reel, of brackets mounted on the reel-arms, sprocket-wheels mounted on the brackets, chains carried by the sprockets, worm-wheels fast on the sprocket-spindles, a worm engaging each worm-wheel, a star-wheel mounted on the worm-spindle, and means for automatically actuating each star-wheel as the reel is rotated, whereby the chains are actuated for the purpose set forth.



3. The combination with the reel, of sprocket-wheels mounted on the reel-arms, endless chains mounted on the sprocket-wheels and extending substantially parallel to the axis of the reel, said chains being provided with notches for the convolutions wound on the reel, and means for actuating the chains as the reel is rotated.

4. In a machine of the class described, the combination with the reel, of sprocket-wheels mounted on the reel-arms, endless chains carried by the sprocket-wheels, and provided with notches, pins also mounted on the chains in line with the notches, and means for automatically actuating the chains as the reel is rotated.

708,185. MAGNETIC SEPARATOR. JOHN P. WETHERILL, South Bethlehem, Pa. Filed Aug. 20, 1901. Serial No. 73,297. (No model.)



Claim.—1. A magnetic separator comprising magnet-poles spaced apart to form an intervening gap traversed by the magnetic lines of force, means for feeding into said gap the material to be separated, means for washing out the non-attracted particles from the particles detained by magnetic attraction in said gap, and a scraper for removing the attracted particles, said scraper having projections which scrape both pole-pieces; substantially as described.

2. A magnetic separator comprising an upper magnet-pole and a lower magnet-pole spaced apart to form an intervening gap traversed by the magnet lines of force, means for feeding into said gap the material to be separated, means for washing out the non-attracted particles from the particles detained by magnetic attraction in said gap, and a scraper having its path of movement through the gap, and provided with a series of scraper-blades extending transversely of the gap in such manner as to scrape both pole-pieces; substantially as described.

3. A magnetic separator, comprising an upper magnet-pole and a lower magnet-pole spaced apart to form an intervening gap, said magnet-poles being pointed or wedge-shaped at their ends to concentrate the lines of force across the gap, means for feeding into said gap the material to be separated, means for washing out the non attracted particles from the particles detained by magnetic attraction in the gap, and a scraper having its path of movement through the gap and provided with scraper-blades of a configuration conforming to the outline of the pole ends, substantially as described.

4. A magnetic separator, comprising magnet-poles separated by an intervening gap traversed by the magnetic lines of force, means for feeding into said gap the material to be separated, a jet-pipe for expelling the non-attracted particles from the particles detained by magnetic attraction in said gap, and a scraper for removing the attracted particles, said scraper having projections which scrape both pole-pieces; substantially as described.

5. A magnetic separator, comprising magnet-poles separated by an intervening gap traversed by the magnetic lines of force, means for feeding into said gap the material to be separated, a jet-pipe for expelling the non-attracted particles from the particles detained by magnetic attraction in said gap, a scraper for removing the attracted particles, and a water vat or tank in which the magnet-poles and jet-pipe are immersed; substantially as described.

6. A magnetic separator, comprising an upper magnet and a lower magnet, of substantially U shape in cross-section and having their opposing poles so related as to form with the core a magnetic circuit with two gaps, means for feeding into said gaps the material to be separated, jet-pipes for expelling the non-attracted particles from the particles detained by magnetic attraction in the gaps, and a scraper consisting of an endless belt provided with a series of scraper-blades having a path of movement successively through the gaps and extending transversely of the gap in such manner as to scrape both pole-pieces; substantially as described.

7. A magnetic separator, comprising an upper magnet-pole and a lower magnet-pole spaced apart to form an intervening gap, means for feeding into said gap the material to be separated, a vat or tank containing water in which the magnet-poles are submerged, a scraper operating within the gap, a jet-pipe having its jet-openings directed through the gap, laterally-disposed hoppers to receive the non-attracted particles, and an end hopper to receive the attracted particles as they are conveyed to it by the scraper; substantially as described.

8. A magnetic separator, consisting of upper and lower U-shaped magnets whose poles are so arranged as to form a magnetic circuit with two gaps, outlying hoppers for supplying to said gaps the material to be separated, jet-pipes whose jets are directed through the gaps on the opposite side to the feed, an endless belt carrying scraper-blades having a path of movement successively through the gaps, laterally-disposed hoppers to receive the non-attracted particles, and an end hopper to receive the attracted particles as they are conveyed to it by the scraper; substantially as described.

9. A magnetic separator, provided with an interpolar gap, means for feeding into said gap the material to be separated, a water-containing tank within which the separator-poles are submerged, a jet-pipe whose jets are directed through the gap, and means for removing the particles detained in the gap by magnetic attraction; substantially as described.

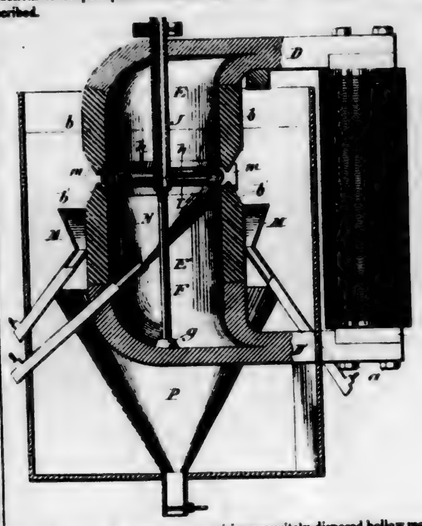
10. A magnetic separator, provided with an interpolar gap, means for feeding laterally into said gap the material to be separated, a water-containing tank within which the separator-poles are submerged, a jet-pipe whose jets are directed laterally through the gap, and a longitudinally-moving scraper; substantially as described.

708,186. MAGNETIC SEPARATOR. JOHN P. WETHERILL, South Bethlehem, Pa. Filed Aug. 20, 1901. Serial No. 73,298. (No model.)

Claim.—1. A magnetic separator, comprising oppositely-disposed hollow magnet-poles, separated by an interpolar space or gap traversed by the magnetic lines of force, means for feeding into said gap the material to be separated, means for washing out the non-attracted particles from the particles detained by magnetic attraction in said gap, and a scraper for removing the attracted particles beyond the detaining influence of the magnetic field; substantially as described.

2. A magnetic separator, comprising oppositely-disposed hollow magnet-poles, separated from each other by an interpolar space or gap traversed by the magnetic lines of force said poles having alternate magnetic and non-magnetic zones or sections along their peripheries, means for feeding into the interpolar space or gap the material to be separated, means for washing out the non-attracted particles from the particles detained by magnetic attraction in said gap, and a scraper having its path of movement successively through the gaps, laterally-disposed hoppers to receive the non-attracted particles, and an end hopper to receive the attracted particles as they are conveyed to it by the scraper; substantially as described.

3. A magnetic separator, comprising oppositely-disposed hollow magnet-poles, separated by an interpolar space or gap traversed by the magnetic lines of force, said poles having alternate magnetic and non-magnetic zones or sections along their peripheries, feeding-hoppers for supplying the material to be separated to the magnetic portions of the gap between the magnetic zones or sections, a water-jet pipe having its jet-apertures directed through the gap, and a series of scraper-blades operating within the gap; substantially as described.



4. A magnetic separator, comprising oppositely-disposed hollow magnet-poles, separated by an interpolar space or gap traversed by the magnetic lines of force, said poles having alternate magnetic and non-magnetic zones or sections along their peripheries, the non-magnetic zones or sections being of approximately the form of triangular prisms so as to concentrate the lines of force through the magnetic zones or sections, means for feeding the material to be separated to the magnetic portions of the gap, means for washing out the non-attracted particles from the particles detained by magnetic attraction in the gap, and a scraper operating in the gap for removing the attracted particles from the magnetic to the non-magnetic sections of the pole-pieces and releasing them thereat; substantially as described.

5. A magnetic separator, comprising oppositely-disposed hollow magnet-poles, separated by an interpolar space or gap traversed by the magnetic lines of force, said poles having alternate magnetic and non-magnetic zones or sections, hoppers for feeding the material to be separated into the magnetic portions of the gap, a rotatory hollow shaft within the magnet-poles, an annular jet-pipe carried by said shaft and in communication with its hollow interior, and scraper-blades operating in the interpolar gap and mounted upon said annular pipe; substantially as described.

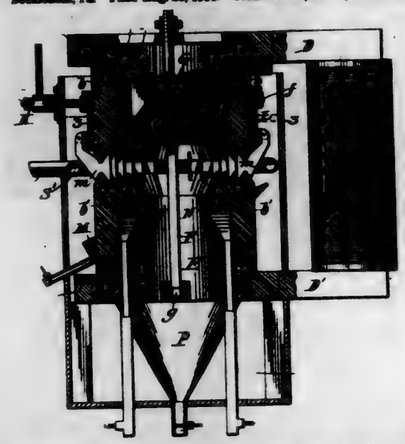
6. A magnetic separator, comprising oppositely-disposed hollow magnet-poles, separated by an interpolar space or gap traversed by the magnetic lines of force, said poles having alternate magnetic and non-magnetic zones or sections, hoppers for feeding the material to be separated into the magnetic portions of the gap, a rotatory hollow shaft within the magnet-poles, an annular jet-pipe, carried by said shaft and in communication with its hollow interior, scraper-blades operating in the interpolar gap and mounted upon said annular pipe, receiving-hoppers for heads arranged opposite the non-magnetic sections of the pole-pieces, and a separate receiving-hopper for tailings; substantially as described.

7. A magnetic separator, comprising oppositely-disposed hollow magnet-poles, separated by an interpolar space or gap traversed by the magnetic lines of force, said poles having alternate magnetic and non-magnetic zones or sections, hoppers for feeding the material to be separated into the magnetic portions of the gap, a rotatory hollow shaft within the magnet-poles an annular jet-pipe carried by said shaft and in communication with its hollow interior, scraper-blades operating in the interpolar gap and mounted upon said annular pipe, receiving-hoppers for heads arranged opposite and outside of the non-magnetic sections, an additional receiv-

ing-hopper for heads arranged within the lower magnet-pole, and a separate receiving-hopper for tailings; substantially as described.

8. A magnetic separator, provided with an electromagnet having a flattened core and flattened lateral projections from said core, said flattened projections terminating in hollow tubular pole-pieces, separated from each other by an interpolar space or gap traversed by the magnetic lines of force; substantially as described.

708,187. MAGNETIC SEPARATOR. JOHN P. WETHERILL, South Bethlehem, Pa. Filed Aug. 26, 1901. Serial No. 73,290. (No model.)



Claim.—1. A magnetic separator, comprising hollow tubular magnet-poles, separated by an interpolar space or gap traversed by the magnetic lines of force, a distributing-cone within the upper pole for directing the material to be separated into said gap, a water-jet pipe whose jet-orifices are directed into the gap, and a scraper operating in the gap; substantially as described.

2. A magnetic separator, comprising hollow tubular magnet-poles, separated by an interpolar space or gap traversed by the magnetic lines of force, a distributing-cone within the upper pole for directing the material to be separated into said gap, a water-jet pipe whose jet-orifices are directed into the gap, and a scraper operating in the gap, said scraper consisting of a series of scraper-blades mounted upon a rotatable carrier-ring; substantially as described.

3. A magnetic separator, comprising hollow tubular magnet-poles, separated by an interpolar space or gap traversed by the magnetic lines of force, a distributing-cone within the upper pole for directing the material to be separated into said gap, a water-jet pipe whose jet-orifices are directed into the gap, and a scraper operating in the gap, said scraper consisting of a series of scraper-blades mounted upon a rotatable carrier-ring, said ring being carried by the upper tubular magnet and the scraper-blades being hinged thereto; substantially as described.

4. A magnetic separator, comprising hollow tubular magnets, separated by an interpolar space or gap traversed by the magnetic lines of force, said poles being provided with alternate magnetic and non-magnetic zones or sections along their peripheries, a distributing-cone within the upper pole for directing the material to be separated into the magnetic portions of the gap, a water-jet pipe exterior to the gap and whose jet-orifices are directed inwardly into the gap, and scraper-blades operating within the gap; substantially as described.

5. A magnetic separator, comprising hollow tubular magnets, separated by an interpolar space or gap traversed by the magnetic lines of force, said poles being provided with alternate magnetic and non-magnetic zones or sections along their peripheries, a distributing-cone within the upper pole for directing the material to be separated into the magnetic portions of the gap, a water-jet pipe exterior to the gap and whose jet-orifices are directed inwardly into the gap, scraper-blades operating within the gap, a receiving-hopper for tailings arranged below the hollow interior of the magnet, and receiving-hoppers for heads arranged opposite the non-magnetic sections of the poles; substantially as described.

6. A magnetic separator, comprising two hollow tubular magnet-poles, separated by an interpolar space or gap traversed by the magnetic lines of force, means for feeding the material to be separated to said gap from within the magnet, an outlying annular water-jet pipe having its jet-orifices directed inwardly into the gap, a scraper operating within the gap, and suitable receiving-hoppers for the heads and tailings; substantially as described.

7. A magnetic separator, provided with hollow tubular magnet-poles, separated by an interpolar space or gap traversed by the magnetic lines of force, the upper of said poles serving as a feed-hopper to the gap, said poles being clamped within laterally-projecting extensions of the magnet-core; substantially as described.

708,188. LIGHTNING-ROD. JAMES O. WILSON, Canton, Mo. Filed Jan. 6, 1902. Serial No. 88,864. (No model.)

Claim.—1. A lightning-rod comprising a continuous conductor extending from an elevated point to a plurality of ground connections, and composed ground-plates to which the terminals of the conductor are electrically connected.

2. A lightning-rod comprising a continuous conductor having a plurality of ground connections, loops connected continuously to the conductor and extending therabove to form attractive points, and composed ground-plates to which the terminals of said conductor are electrically connected.

3. A lightning-rod comprising a continuous conductor extending from an elevated point to a ground-plate, said conductor being branched or divided, and a ground-plate to which the branched or divided portions of the conductor are connected.

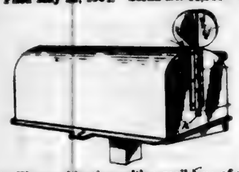
4. A grounding connection for a lightning-rod comprising a bed of charcoal arranged below the surface of the ground, and a composite plate embedded in the charcoal and electrically connected to the conductor.

5. A grounding-plate for a lightning-rod, comprising superposed sheets of galvanized iron, zinc, lead and copper, arranged in the order named.

6. A grounding-plate for lightning-rods, comprising a series of superposed plates of different electrical properties, the outer of said plates having its edge portions folded over the edges of the remaining plates and binding the same together.

7. The combination with a lightning-rod, of a ground-plate to which said rod is connected, the terminals of said rod extending through and below said plate, substantially as specified.

708,189. SIGNALING-TARGET. GEORGE A. WIRT, Pugit township, Ind. Filed May 29, 1901. Serial No. 61,560. (No model.)

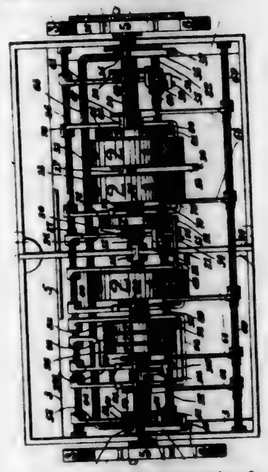


Claim.—1. The combination, with a mail-box, of a signaling-target therefor comprising a socket or bearing, a stem bearing the signaling-target on its upper end mounted to extend through and slide and turn in said bearing, being provided with a head below said bearing for limiting the movement of said stem, and a detent with which said target is adapted to engage and be thereby held in adjusted position, substantially as set forth.

2. The combination, in a target, of a suitable vertically-arranged bearing, a stem adapted to be inserted and revolve in said bearing and provided with a head on the lower end thereof, wings secured to the upper end of said stem, and a keeper having a notch therein into which an edge of one of the wings may enter, said stem being of sufficient length to permit a longitudinal movement in the bearing, substantially as set forth.

3. The combination, in a target, of a bearing, a stem mounted therein, wings secured on said stem, and a V-shaped keeper secured alongside of said stem and adapted to receive an edge of one of the wings, substantially as and for the purposes set forth.

708,190. CASH-REGISTER. AUGUSTUS L. WOOD, Cincinnati, Ohio, assignor of one-half to Edward C. Bidmann, Cincinnati, Ohio. Filed June 18, 1898. Serial No. 683,825. (No model.)



Claim.—1. In a cash-register, the combination of a shaft, sales indicating and registering mechanisms mounted thereon, a cash-drawer, operating-wheels arranged in position at one end of the shaft to be engaged and moved by the hand of the operator in actuating said mechanism, a latch for holding the cash-drawer in closed position, a movable part arranged adjacent the wheels to be struck by the hand, and a link connection between said latch and said movable part, substantially as set forth.

2. In a cash-register, the combination of a series of indicating-disks, shafts whereon said disks are mounted, operating-wheels for said shafts, a cash-drawer, a latch arranged to hold said drawer closed and mechanism for releasing the cash-drawer and limiting the movement of said shafts, said mechanism comprising a cranked shaft connected to the latch and having its end in the path of the hand of the operator in turning said operating-wheels, substantially as set forth.

3. In a cash-register, the combination of indicating mechanisms comprising indicating-disks having shafts and provided with means for turning them to indicate sales, dog-and-ratchet devices for holding the disks, when turned, against back rotation, arms adapted, when the dogs are disengaged from their ratchets, to engage and hold said dogs out of operation, fingers on the shaft to move said arms out of engagement with the dogs when the shaft is turned, a cash-drawer, and mechanism, actuated from the movement of the cash-drawer, for moving the dogs to disengage them from their ratchets, substantially as set forth.

4. In a cash-register, the combination of indicating mechanism comprising indicating-disks and means for turning same to indicate sales, dog-and-ratchet devices for holding the disks, when turned, against back rotation, a cash-drawer, mechanism, actuated from the movement of the cash-drawer, for throwing said dog-and-ratchet devices out of operation to permit the indicating-disks to be returned to their normal positions, and means actuated from the movement of the indicating-disks, when turned to indicate a sale, for placing said dog-and-ratchet devices in operation, substantially as set forth.

5. A cash-register comprising a shaft, indicating and registering disks arranged thereon, a series of pivoted yokes embracing the indicating-disks, and each provided with arms pivoted at opposite sides of the respective indicating-disk, means for actuating each registering-disk from a corresponding indicating-disk, means for actuating the yokes from the registering-disks, and mechanism for actuating registering-disks from the movement of the yokes, substantially as set forth.

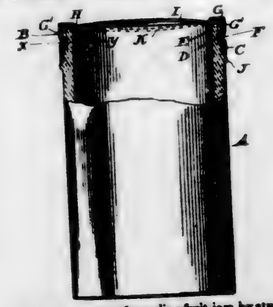
6. A cash-register comprising a sales-indicating device, a dog and ratchet-wheel to hold said device, when actuated to indicate a sale, a cash-drawer, mechanism actuated by the movement of the cash-drawer for disengaging said holding means to permit the sales-indicating device to be retracted, and mechanism to retain said holding means out of operative position when disengaged from the sales-indicating device, substantially as set forth.

7. A cash-register comprising a sales-indicating device, means to hold said device, when actuated to indicate a sale, a cash-drawer, mechanism to disengage the holding means of the sales-indicating device when the cash-drawer is moved and mechanism controlled by the sales-indicating device for retaining said holding means out of operation when disengaged from the sales-indicating device, substantially as set forth.

8. A cash-register comprising a sales-indicating device, means to hold said device, when actuated to indicate a sale, a cash-drawer, mechanism to disengage the holding means of the sales-indicating device when the cash-drawer is moved, a part arranged to engage the holding means and retain the same out of operation when disengaged from the sales-indicating device, and mechanism for releasing said part from engagement with the holding means of the sales-indicating device, substantially as set forth.

9. In a cash-register, the combination of a shaft, two indicating-disks arranged side by side thereon, and provided with actuating devices, a registering-disk on said shaft at each side of said indicating-disks, means to actuate each registering-disk from a corresponding indicating-disk, a movable yoke having arms embracing the two indicating-disks, said yoke being pivoted at the ends of its arms, means for moving the yoke through one of its arms from one of the registering-disks and means for actuating the other registering-disk from the other arm of the yoke, substantially as set forth.

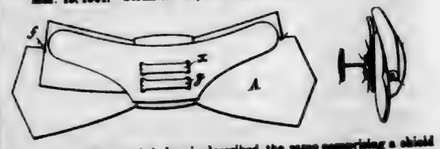
708,191. VACUUM FRUIT-JAR-SEALING DEVICE. SAMUEL ADLAM, New York, N. Y. Filed Nov. 22, 1901. Serial No. 83,313. (No model.)



Claim.—1. In an apparatus for sealing fruit-jars by atmospheric pressure, the combination consisting of neck of the jar, provided with the recess as D; the compressible ring as C, located in recess D; the barrel of the sealing-cap as B, provided with an inwardly-formed depression as *V*, constructed to engage with ring C; a top surface turned inwardly from barrel B and provided with a recess G; a packing G', located therein; the top surface of the cap being formed with a spring stamped in the metal, all constructed, arranged and combined to operate substantially as hereinbefore specified.

2. As an article of manufacture, a vacuum fruit-jar cover, constructed with a vertical rim provided with a depression in it, the top surface of said cover being formed with a convex central portion, struck up in the metal and forming a spring, substantially as and for the purposes specified.

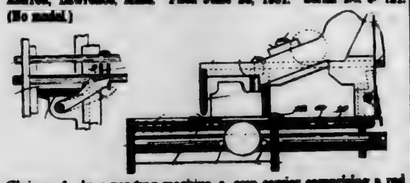
708,192. NECKTIE. FREDERICK A. ARENDS, Hoboken, N. J. Filed Mar. 15, 1901. Serial No. 51,236. (No model.)



Claim.—The necktie herein described, the same comprising a shield having centrally disposed upon its rear surface, a series of strips parallel with each other, attached at each of their extremities to the shield, but

free between said extremities, whereby a collar hook-button may be inserted, as herein shown and described, between the strips and the shield.

708,198. COIN-CONTROLLED VENDING APPARATUS. GEORGE ARTHUR, Lawrence, Mass. Filed June 26, 1901. Serial No. 67 121. (No model.)



Claim.—1. In a vending-machine, a coin-carrier comprising a rod having projections extended therefrom substantially at right angles to the longitudinal axis of said rod to sustain the edge of a coin at two points, a plate having a slot and provided with a depending guide independent of said coin-carrier to act on one side of a coin as it passes through said throat to enter the space between and to be sustained by said projections.

2. In a vending-machine, a coin-carrier comprising a rod having projections extended therefrom substantially at right angles to the longitudinal axis of said rod to sustain the edge of a coin at two points, a plate having a slot and provided with a depending stationary guide to act on one side of a coin as it passes through said throat to enter the space between and to be sustained by said projections, a package-holder containing packages to be delivered, a package-delivering device having a projection located above the projections of the coin-carrier whereby as the coin-carrier is moved toward the package-holder the coin sustained by the projections of said carrier will move the package-delivering device in unison with it to meet and deliver a package.

3. In a vending-machine, a coin-receiving throat, a coin-carrier composed of a sliding rod having lateral coin-supporting projections extended from one side thereof substantially at right angles to the longitudinal axis of the coin-carrier and being separated for a distance less than the diameter of the coin which must be used to effect the delivery of a package, combined with a stationary guide located at one side said coin-carrier and acting upon one side of the coin entering the space between said projections, and means to actuate said coin-carrier to slide one face of the coin along the face of the guide.

4. In a vending-machine, a coin-receiving throat, a coin-carrier composed of a sliding rod having lateral coin-supporting projections extended from one side thereof substantially at right angles to the longitudinal axis of the coin-carrier and being separated for a distance less than the diameter of the coin which must be used to effect the delivery of a package, combined with a stationary guide located at one side said coin-carrier and acting upon one side of the coin entering the space between said projections, means to actuate said coin-carrier to slide one face of the coin along the face of the guide, a package-delivering device having a projection to be engaged by the coin sustained by the coin-carrier, and a spring-controlled pick-off acting upon the face of the coin which was in contact with the guide to thereby aid in maintaining the coin in operative position in the coin-carrier.

5. In a vending-machine, a coin-receptacle, a coin-throat, a stop set counting therewith to engage and arrest a false coin of magnetic material, a coin-carrier provided with projections extended therefrom substantially at right angles to the longitudinal axis of said carrier to sustain a good coin, and a clearer, said clearer being located sufficiently behind the projection of said carrier to have a space between said projections and carrier through which the false coin detached by said clearer may drop into the coin-receptacle.

6. In a vending-machine, a coin-carrier having lateral projections to sustain the edges of a coin at two points, a coin-throat to receive a coin and guide the same into position between said projections, a magnet located in the direction of travel of the coin to engage and arrest a false coin of magnetic material, a clearer operatively connected with said coin-carrier, and means to actuate the coin-carrier and the clearer, the clearer acting upon the edge of a false coin held by the magnet and detaching it from the magnet that it may continue its movement through the throat, the projections of the coin-carrier having been moved out of the range of the descent of the false coin so that the coin is not arrested by the coin-carrier.

7. In a vending-machine, a coin-carrier having extended from it lateral projections separated for a distance less than the diameter of the coin required to enable a package to be delivered, a spring-controlled coin pick-off located at one side of the coin-carrier and kept pressed normally against one face of the moving coin as the carrier is moved to carry the coin past the position of the pick-off and to effect the discharge of a package.

8. In a vending-machine, a coin-carrier having lateral projections to sustain a coin by its edge, a package-delivering device located above said coin-carrier and having a projection to be acted upon by the edge of said coin, a presser to act upon the upper edge of said coin and keep the same seated on said projections, a spring-controlled pick-off located at one side of said coin-carrier and having a heel to prevent the coin-carrier from returning to its normal position until said carrier has been moved sufficiently far to cause the delivery of a package.

9. In a vending-machine, a coin-carrier having lateral projections between its ends extended therefrom at substantially right angles to the longitudinal axis of said carrier to sustain a coin of the proper diameter, combined with a coin-throat having a guide coöperating therewith to guide the coin as it is being seated on the projections of the coin-carrier.

10. In a vending-machine, a coin-carrier having projections to sustain the edge of a coin of proper diameter, a spring-controlled coin pick-off acting in a yielding manner upon the exposed side of the coin being moved by the coin-carrier, the spring moving the free end of the coin pick-off into a position across the path of movement of the coin as the coin passes the free end of the pick-off whereby as the coin-carrier is retracted the coin pick-off meets the edge of the coin and discharges it from said projections.

11. In a vending-machine, a coin-carrier having projections to sustain a coin of the proper diameter, an inclined throat to receive a coin and lead it into position between said projections, a yielding spring-sustained clearer located in said throat and having an inclined acting edge whereby said edge meeting an obstruction stuffed into the slot may remove the same.

12. In a vending-machine, a coin-carrier having projections to sustain a coin, a throat having an inclined guideway to receive a coin and conduct it between the projections of the coin-carrier, a yielding clearer carried by said coin-carrier and movable in said throat as the coin-carrier is moved, whereby the breaking of the clearer may be obviated in case of a fixed obstruction placed in said throat.

13. In a vending-machine, a coin-carrier having lateral projections between its ends to sustain and carry a coin, a separate slotted throat to receive and direct coin in position between the projections of the coin-carrier, a package-delivering device sustained independently of said carrier and located between said coin-carrier and said throat and adapted to be moved by a coin sustained by the coin-carrier, combined with a guard-plate interposed between said throat and said package-delivering device to prevent the movement of the package-delivering device by an instrument inserted through the slot in said throat.

14. In a vending-machine, a sliding coin-carrier having extended from its side between its ends projections separated for a distance less than the diameter of the coin required, to enable a package to be delivered, an independently-sustained package-delivering device surrounded by a spring and having a projection adapted to be acted upon by the coin sustained by the coin-carrier, said coin causing the package-delivering device to be moved in unison with the coin-carrier.

15. In a vending-machine, a frame, a series of connected coin-carriers, and an actuating device to slide the series of coin-carriers in said frame, combined with a series of package-delivering devices sustained in said frame above the coin-carrier, a spring for each of said devices to normally retract it from its operative position, each delivering device being adapted to be moved independently of the other by a coin in the coin-carrier below it.

708,194. TILING. GEORGE H. BENNETT, New York, N. Y. Filed Jan. 13, 1902. Serial No. 90,228. (No model.)

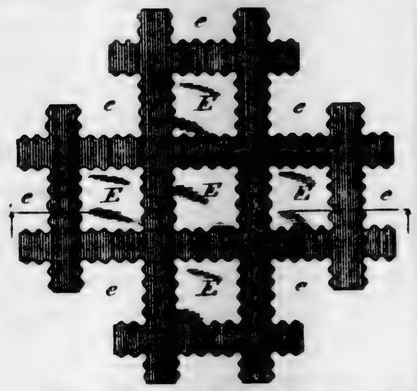
Claim.—1. A floor-covering, comprising the combination of tiles having arms, formed with corrugated or serrated edges, said arms arranged in juxtaposition to form spaces between them, and block-tiles the edges of which are correspondingly corrugated or serrated fitting within and filling the spaces between the arms.

2. A floor-covering, comprising the combination of a plurality of removable cross and block tiles, the cross-tiles having arms, the extremities of which are arranged in juxtaposition to form spaces between them, and the block-tiles fitting within and filling the spaces between the arms, the edges of all of the tiles being formed with corresponding corrugations or serrations adapted to engage and intermesh.

3. A tile floor covering, consisting of a plurality of removable tiles, all of the tiles being formed with corrugated or serrated edges, the corrugations or serrations being symmetrical in form, their central axes extending at right angles from the edges of the tiles, and being at right angles to their surfaces, the formation of the edges in all the tiles corresponding and being adapted to engage and intermesh throughout.

4. The combination with a block-tile of two tiles, each in the form of a double heraldic cross, the adjoining arms of the crosses forming spaces adapted to receive and contain various-formed block-tiles, and all being removable.

5. The combination with block-tiles of tiles, each in the form of a double heraldic cross, the adjoining arms of the crosses forming spaces adapted to receive and contain the block-tiles, the edges or margins of all of the tiles being formed with corrugations or serrations of equal dimensions, and adapted to intermesh, engage and be removable.

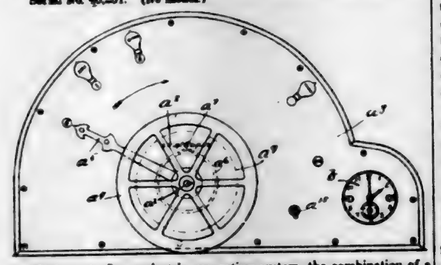


6. A floor-tile comprising cross-tiles, the arms of which are arranged in juxtaposition to each other forming inclosed spaces, and block-tiles adapted to fit into and fill said spaces, the edges of all of the tiles being formed with corresponding and engaging corrugations or serrations arranged at right angles to the surfaces of the tiles.

7. A floor-covering, comprising the combination of tiles having arms, the extremities of which are arranged in juxtaposition to one another to form spaces between them and a plurality of subdivided block-tiles fitting within and filling the spaces between the arms, and all being removable.

8. A floor-covering, comprising the combination of cross-tiles having arms the extremities of which are arranged in juxtaposition to form spaces between them, and a plurality of block-tiles fitting within and filling the spaces between the arms, said block-tiles uniting to fill the space between the said arms and formed with corrugated or serrated outer edges, the serrations in the block-tiles corresponding and adapted to intermesh with the serrations in the arms.

708,195. CONTROLLING DEVICE FOR ELECTRIC GENERATING SYSTEMS. JOHN H. RICKFORD, Salem, Mass. Filed Dec. 18, 1900. Serial No. 40,251. (No model.)



Claim.—1. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it a starting device for starting said power generating and converting apparatus and a device for closing the dynamo-circuit containing the translating devices having an operating device by which it is operated, substantially as described.

2. In an electric generating system, the combination of a dynamo a power generating and converting apparatus for operating it, a starting device for starting said power generating and converting apparatus, a device for closing the dynamo-circuit containing the translating devices and an operating device for operating said starting device and also said circuit-closing device, substantially as described.

3. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a starting device for starting said power generating and converting apparatus and a device for cutting out the resistances of the shunt field-circuit of the dynamo and for closing the dynamo-circuit containing the translating devices, having an operating device by which it is operated, substantially as described.

4. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a starting device for starting said power generating and converting apparatus and a device for closing the dynamo-circuit, having an operating device by which it is operated, and an automatic locking device for holding said starting device while the power generating and converting apparatus starts, substantially as described.

5. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a starting device for starting said power generating and converting apparatus and a device for closing the dynamo-circuit containing the translating devices, having an operating device by which it is operated, and automatic means for preventing the starting device from closing the dynamo-circuit until after the power generating and converting apparatus starts, substantially as described.

6. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a starting device for starting said power generating and converting apparatus and a device for cutting out the resistances of the shunt field-circuit of the dynamo and for also closing the dynamo-circuit containing the translating devices having an operating device by which it is operated, and an automatic locking device for preventing said device from cutting out the resistances of the shunt field-circuit of the dynamo and for closing the dynamo-circuit until after said power generating and converting apparatus has started, substantially as described.

7. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it, and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for also starting said power generating and converting apparatus, having an operating device by which it is operated, substantially as described.

8. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it, and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for starting said power generating and converting apparatus and a device for closing the dynamo-circuit containing the translating devices, having an operating device by which it is operated, substantially as described.

9. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for starting said power generating and converting apparatus and a device for closing the dynamo-circuit containing the translating devices, and an operating device for operating said starting device and also said circuit-closing device, substantially as described.

10. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it, and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for starting said power generating and converting apparatus and a device for cutting out the resistances in the shunt field-circuit of the dynamo and for closing the dynamo-circuit containing the translating devices, having an operating device by which it is operated, substantially as described.

11. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it, and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power and converting apparatus and for starting said power generating and converting apparatus, means for cutting out the resistances in the shunt field-circuit of the dynamo and for closing the dynamo-circuit containing the translating devices, and an operating device for operating said starting device and also said means for cutting in the dynamo and for closing the dynamo-circuit, substantially as described.

12. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the

admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for also starting said power generating and converting apparatus, having an operating device by which it is operated and an automatic locking device for holding said starting device while the power generating and converting apparatus starts, substantially as described.

13. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it, and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for starting said power generating and converting apparatus and a device for closing the dynamo-circuit containing the translating devices, having an operating device by which it is operated, and automatic means for preventing it circuit-closing device from closing the dynamo-circuit until after the power generating and converting apparatus has started, substantially as described.

14. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it, and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for starting said power generating and converting apparatus, and a device for cutting out the resistances in the shunt field-circuit of the dynamo and for closing the dynamo-circuit containing the translating devices, having an operating device by which it is operated, and an automatic locking device for preventing the device from cutting out the resistances of the shunt field-circuit of the dynamo and for closing the dynamo-circuit until after said power generating and converting apparatus has started, substantially as described.

15. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it, and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for also starting said power generating and converting apparatus, having an operating device by which it is operated, and an automatic locking device for holding said starting device while the vaporizer acts to vaporize the liquid hydrocarbon, substantially as described.

16. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it, and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for also starting said power generating and converting apparatus, having an operating device by which it is operated, an automatic locking device for holding said starting device while the vaporizer acts to vaporize the liquid hydrocarbon, and another automatic locking device for holding said starting device while the power generating and converting apparatus starts, substantially as described.

17. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a starting device for starting said power generating and converting apparatus comprising a battery, circuits leading therefrom including the operating devices for starting said power generating and converting apparatus, and means for operating said circuits, and a switch for closing the dynamo-circuit containing the translating devices and means for operating it, substantially as described.

18. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a starting device for starting said power generating and converting apparatus comprising a battery, circuits leading therefrom including the operating devices for starting said power generating and converting apparatus, means for operating said circuits, and a switch for closing the dynamo-circuit containing the translating devices, and an operating device for operating said starting device and also said switch, substantially as described.

19. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a starting device for starting said power generating and converting apparatus, comprising a battery, circuits leading therefrom including the operating devices for starting said power generating and converting apparatus, means for operating said circuits, and means for cutting out the resistances of the shunt field-circuit of the dynamo, a switch for closing the dynamo-circuit including the translating devices and means for operating it, substantially as described.

20. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it, and a starting device for starting said power generating and converting apparatus comprising a battery, circuits leading therefrom including the operating devices for starting said power generating and converting apparatus, and means for operating said circuits, combined with an automatic locking device for holding the starting device while the power generating and converting apparatus starts, substantially as described.

21. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a starting device for starting said power generating and converting apparatus comprising a battery, circuits leading therefrom including the operating devices for starting said power generating and converting apparatus, and means for operating said circuits, and a switch for closing the dynamo-circuit containing the translating devices, means for operating it, and means for preventing the operation of said switch until after the power generating and converting apparatus starts, substantially as described.

22. In an electric generating system, the combination of a dynamo a power generating and converting apparatus for operating it, a starting device for starting said power generating and converting apparatus comprising a battery, circuits leading therefrom including the operating devices for starting said power generating and converting apparatus, and means for operating said circuits, a device for cutting out the resistances of the shunt field-circuit of the dynamo, a switch for closing the dynamo-circuit containing the translating devices, means for operating it, and an automatic locking device for holding said device to prevent cutting out the resistances of the shunt field-circuit of the dynamo, and for holding the switch to prevent closing the dynamo-circuit until after the power generating and converting apparatus starts, substantially as described.

23. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, and a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for also starting said power generating and converting apparatus, comprising a battery, circuits leading therefrom including the operating devices which control said vaporizer and start said power generating and converting apparatus, switches for said circuits, and means for operating said switches successively, substantially as described.

24. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus and a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for starting said power generating and converting apparatus, comprising a battery, circuits leading therefrom including the operating devices which control said vaporizer and start said power generating and converting apparatus, and switches for said circuits, and a switch for closing the dynamo-circuit, and means for operating said switches successively, substantially as described.

25. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus and a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for starting said power generating and converting apparatus comprising a battery, circuits leading therefrom including the operating devices which control said vaporizer and start said power generating and converting apparatus, and switches for said circuits, and means for cutting out the resistances of the shunt field-circuit of the dynamo, a switch for closing the dynamo-circuit, and means for successively operating said battery-circuit switches, resistances and dynamo-circuit switch, substantially as described.

26. In an electric generating system, the combination of a dynamo a power generating and converting apparatus for operating it, a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus and a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for also starting said power generating and converting apparatus, comprising a battery, circuits leading therefrom including the operating devices which control said vaporizer and start said power generating and converting apparatus, switches for said circuits, and means for operating said switches successively, and an automatic locking device for holding said starting device while the vaporizer acts to vaporize the liquid hydrocarbon, substantially as described.

27. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus and a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for starting said power generating and converting apparatus, comprising a battery, circuits leading therefrom including the operating devices which control said vaporizer and start said power generating and converting apparatus, and switches for said circuits, and a switch for closing the dynamo-circuit, means for operating said switches successively, and automatic means for preventing the switch from closing the dynamo-circuit until after the power generating and converting apparatus has started, substantially as described.

28. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus and a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus and for starting said power generating and converting apparatus, comprising a battery, circuits leading therefrom including the operating devices which control said vaporizer and start said power generating and converting apparatus, and switches for said circuits, and a switch for closing the dynamo-circuit, means for operating said switches successively, an automatic locking device for holding said starting device while the vaporizer acts to vaporize the liquid hydrocarbon, and another automatic locking device for holding said starting device until the power generating and converting apparatus starts, substantially as described.

29. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it, and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus, having an operating device by which it is operated, and an automatic locking device for holding the starting device while the vaporizer acts to vaporize the liquid hydrocarbon, substantially as described.

30. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it, and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus, having an operating device by which it is operated, and a locking device for holding the starting device while the vaporizer acts to vaporize the liquid hydrocarbon, and a thermal device operated by the vaporizer for operating said locking device to release the starting device, substantially as described.

31. In an electric generating system, a dynamo, a power generating and converting apparatus for operating it, and a vaporizer for vaporizing liquid hydrocarbon which is delivered to said power generating and converting apparatus, combined with a starting device for controlling the admission of liquid hydrocarbon to the vaporizer and for controlling the delivery therefrom to the power generating and converting apparatus, comprising a battery, circuits leading therefrom, including the operating devices which control said vaporizer, switches for said circuits, means for operating them, and a locking device for holding the starting device while the vaporizer acts to vaporize the liquid hydrocarbon, and a thermal device operated by said vaporizer for operating said locking device to release the starting device, substantially as described.

32. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, and a starting device for starting said power generating and converting apparatus comprising an electromagnetically-operated device for controlling the admission of hydrocarbon to the burner of said power generating and converting apparatus, and an automatic igniting device for said burner, a battery, circuits leading therefrom including said electromagnetically-operated controlling device and said igniting device, and means for operating said circuits, substantially as described.

33. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, and a starting device for starting said power generating and converting apparatus comprising a vaporizer, a heating-coil therefor, an electromagnetically-operated device for controlling the admission of hydrocarbon to the burner of said power generating and converting apparatus, and an automatic igniting device for said burner, a battery, circuits leading therefrom including the heating-coil of the vaporizer, the electromagnetically-operated controlling device and said igniting device, and means for operating said circuits, substantially as described.

34. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, and a starting device for starting said power generating and converting apparatus comprising a vaporizer, a heating-coil therefor, an electromagnetically-operated device for controlling the admission of hydrocarbon to the burner of said power generating and converting apparatus, and an automatic igniting device for said burner, a battery, circuits leading therefrom including the heating-coil of the vaporizer, the electromagnetically-operated controlling device and said igniting device, means for operating said circuits, and means for disconnecting said heating-coil from the battery, and for connecting it with the dynamo-circuit, substantially as described.

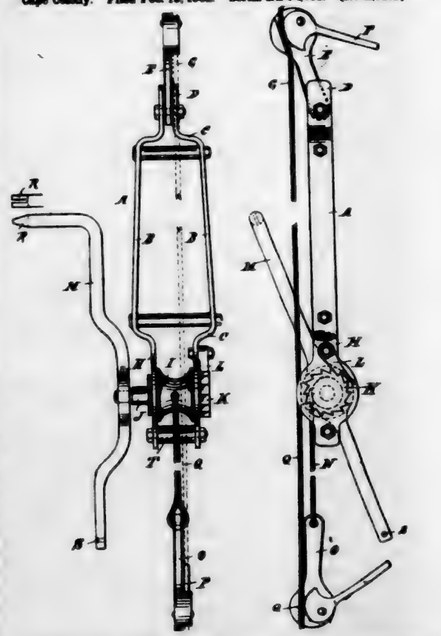
35. In an electric generating system, the combination of a dynamo, a power generating and converting apparatus for operating it, and a starting device for starting said power generating and converting apparatus comprising a battery, circuits leading therefrom including the operating devices for starting said power generating and converting apparatus, means for operating said circuits, a circuit containing the translating devices, a switch for connecting said battery with said circuit, and means for opening said switch and for connecting said circuit with the dynamo-circuit, substantially as described.

36. The combination with a movable contact-pen, of two separated contact-strips insulated from each other adapted to be successively engaged by said contact-pen, a switch for closing an electrical connection between said contact-strips, and means for closing said switch while the contact-pen traverses the gap between said contact-strips, which thereafter opens and breaks the connection, substantially as described.

37. In an electric generating system, a dynamo, a power generating and converting apparatus, a starting device for starting said power generating and converting apparatus, having an operating device by which it is operated, a detent for engaging said starting device and for holding it in its abnormal position, means for operating said detent to release the starting device and means for returning said starting device to its normal position, substantially as described.

38. In an electric generating system, a dynamo, a power generating and converting apparatus, a starting device for starting said power generating and converting apparatus, having an operating device by which it is operated, a detent for engaging said starting device and for holding it in its abnormal position, means for automatically operating said detent to release the starting device, and means for returning said starting device to its normal position, substantially as described.

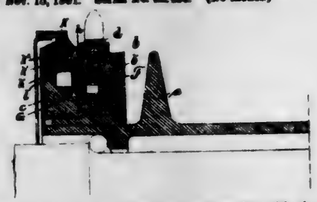
708,196. WIRE-TIGHTENER. SAMUEL W. BRADBURY, Cape Town, Cape Colony. Filed Feb. 19, 1902. Serial No. 94,733. (No model.)



Claim.—In an apparatus of the character described, the combination of two sides similar in configuration spaced apart to form an elon-

gated central space and terminating in a double eye and a secondary frame, a clamp P, pivoted in said double eye, a winch-and-ratchet mechanism mounted in said secondary frame, a clamp O, a flexible connection between said clamp O and said winch, an antifriction-roller carried by said secondary frame between said winch and said clamp and a detachable double lever-handle M whereby said winch may be actuated, substantially as described.

708,197. BRAKE FOR CYCLES. WLADIMIR BRANKOWITSCH, Paris, France, assignor to Compagnie Albert Menthé and Co., Paris, France. Filed Nov. 15, 1901. Serial No. 82,432. (No model.)



Claim.—In brakes for cycles, the combination with the driving-wheel hub and two rings, as *b* and *c*, threaded thereon, of the sprocket-wheel having diametrically opposite cam-surfaces, and a loose ring provided with correspondingly-located inclines adapted to engage said cam-surfaces when the sprocket-wheel is rotated forward, and a second loose ring having inclined surfaces located relatively to those of the first ring in such position as to engage, when the sprocket is rotated backward, cam-surfaces of the sprocket-wheel alternating with those engaged by the inclines of the first-mentioned wheel, substantially as described.

708,198. TROLLEY. JAMES W. BROOKS, Indianapolis, Ind. Filed Jan. 16, 1901. Serial No. 43,437. (No model.)

Claim.—1. In a trolley, the combination of the pivoted head part having the blades provided with the openings therein, the springs having the slots at the free ends thereof and extending through the openings in the blades, the axle extending through said slots and secured to said blades, and the trolley-wheel mounted on said axle between the ends of said springs that have the slots therein, said springs being secured at their opposite ends, substantially as set forth.

2. In a trolley, the combination of the pivoted head part having the blades provided with the openings therein, the springs having the slots at the free ends thereof and extending through the openings in said blades, the axle extending through said slots and secured to said blades near said openings, the trolley-wheel mounted between the ends of said springs that have the slots therein, and the linings between the hub of said wheel and said spring ends, the opposite ends of said springs being secured to the lower part of the head, substantially as set forth.

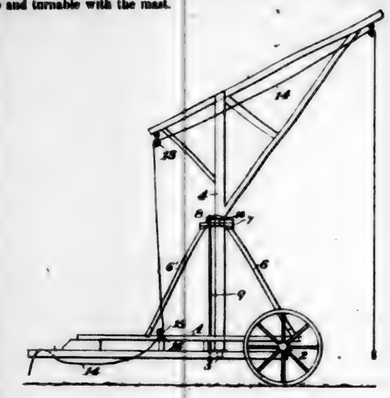
3. In a trolley, the combination with the two-part pivoted head having the trolley-wheel mounted in the pivoted upper part thereof, of the combined guide-springs and electric conductors having bearing connections with the wheel-hub and extending through the sides of the pivoted part to the other part of said head, substantially as set forth.

708,199. PORTABLE HAY-LOADING DERRICK. EDWARD BIXBY, Davisville, Cal. Filed Mar. 27, 1902. Serial No. 100,156. (No model.)

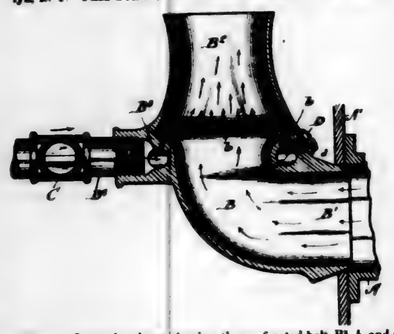
Claim.—1. The combination in a portable derrick of a horizontal A-frame, trapezoidal frames disposed transversely of said frame, divided blocks upon the upper ends of said last-named frames, a journaled mast embraced by said blocks, and having an arm rigid with it, a truss-rod extending through said blocks, and a lower fixed support for said rod.

2. The combination in a portable hay-derrick of a horizontal A-frame, a pillar or mast pivotally supported in relation thereto, trapezoidal frames extending transversely of said A-frame, oppositely-disposed journal-blocks in which the mast is turnable carried on the upper convergent ends of said trapezoidal frames, a vertical truss-rod connecting said blocks and the base of the apparatus whereby the structure is rigidly united, and a jib or arm secured to and turnable with said mast.

3. The combination in a portable hay-derrick, of a base-frame mounted on wheels, said frame having the rear axle rigid therewith and its forward end adapted to be attached to the front axle of an ordinary wagon a mast, trapezoidal frames carried upon the base-frame and supporting said mast, a truss-rod passing vertically between the latter frames, having one end connected therewith and the other end fixed to the base, means for tightening said rod, and an arm secured intermediate of its ends to and turnable with the mast.

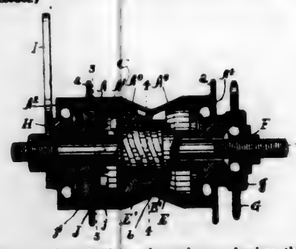


708,200. TUBE-CLEANING DEVICE. JOHN S BRENNELL, Brooklyn, N. Y. Filed Dec. 20, 1901. Serial No. 86,635. (No model.)



Claim.—In a tube-cleaner having the perforated belt B^3, *b*, and provisions B^4 for supplying steam under pressure thereto, a liberal orifice *d* in such belt and means for controlling it adapted to allow the blowing of steam forcibly through such belt past the smaller orifices *b* at intervals to clean the belt, all substantially as herein specified.

708,201. DRIVING, BRAKING, AND COASTING MECHANISM. FRANK B. CASE, Rochester, N. Y., assignor to Riggs-Spencer Company, Rochester, N. Y., a Corporation. Filed June 28, 1901. Serial No. 66,406. (No model.)



Claim.—1. In a driving and coasting mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism extending within the hub; external threads upon the part extending within the hub; surfaces upon the hub adapted to be engaged by an expansible clutch-ring; a self-centering expansible clutch-ring adapted to engage such surfaces; and a clutch-nut upon the threaded portion of the driving mechanism whereby the clutch-ring is expanded into engagement with the hub, substantially as described.

2. In a driving and coasting mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism extending within the hub; external threads upon the part extending within the hub; a part of the hub adapted to be engaged by a clutch-ring; an expansible clutch-ring; and a clutch-nut upon the threaded portion of the driving mechanism whereby the clutch-ring is expanded so as to engage the hub, said nut having a shoulder adapted to support the clutch-ring when said ring is out of engagement, substantially as described.

3. In a driving and coasting mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism extending within the hub; external threads upon the part extending within the hub; conical surfaces A^4 within the hub adapted to be engaged by a clutch-ring; the expansible clutch-ring B^7; and the clutch-nut C upon the threaded portion of the driving mechanism, having conical and cylindrical surfaces c^3, c^4, whereby the clutch-ring is expanded so as to engage the hub, and is supported when out of engagement therewith, substantially as described.

5. In a driving and coasting mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism extending within the hub; external threads upon the part extending within the hub; a part of the hub adapted to be engaged by a clutch-ring; an expansible clutch-ring comprising shoes; a clutch-nut upon the threaded portion of the driving mechanism, whereby the clutch-ring is expanded so as to engage the hub, substantially as described.

6. In a driving and coasting mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism extending within the hub; surfaces upon the hub adapted to be engaged by an expansible clutch-ring; an expansible clutch-ring; a clutch-nut upon the threaded portion of the driving mechanism, whereby the clutch-ring is expanded to engage the hub on forward driving; and projections from the nut whereby the clutch-ring is prevented from rotating with reference to the nut, substantially as described.

7. In a coaster and brake mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism having a part extending within the hub and having threads thereon; a part of the hub adapted to be engaged by a clutch-ring; an expansible clutch-ring; a clutch-nut upon the threaded portion of the driving mechanism, whereby the clutch-ring is expanded so as to engage the hub in forward driving, and a brake mechanism adapted to engage the hub on back pedaling, substantially as described.

8. In a coaster and brake mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism having a part extending within the hub; and having threads thereon; a part of the hub adapted to be engaged by a clutch-ring, and also a part adapted to be engaged by a brake-clutch; a block H within the hub secured against turning; projections h' upon the surfaces of the block H; brake-shoes J notched to receive the projections h', upon the block H; teeth h upon the block H; the spring j; and a clutch-nut upon the threaded portion of the driving mechanism, having the tooth c' on its side, and adapted in forward pedaling to expand the clutch-ring so as to engage the hub, and on back pedaling both to expand the clutch-shoes, and to turn them upon the projections h' so as to brake the hub, substantially as described.

708,202. CUSHION-FRAME FOR BICYCLES. FRANK B. CASE, Rochester, N. Y., assignor to Riggs-Spencer Company, Rochester, N. Y., a Corporation of New York. Filed Aug. 6, 1901. Serial No. 71,088. (No model.)

Claim.—1. In a bicycle, the combination of a rigid front frame, a rear-wheel fork flexibly connected thereto at or near the crank-hanger, a brace flexibly connected to the rear portion of the front frame and comprising as one section concentric tubes, a tube fitting air-tight the space between said concentric tubes whereby the two sections may telescope one into the other, a spring within said tubes for extending said sections

whereby the clutch-ring is expanded so as to engage the hub, substantially as described.

2. In a driving and coasting mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism extending within the hub; external threads upon the part extending within the hub; surfaces upon the hub adapted to be engaged by an expansible clutch-ring; a self-centering expansible clutch-ring adapted to engage such surfaces; and a clutch-nut upon the threaded portion of the driving mechanism whereby the clutch-ring is expanded into engagement with the hub, substantially as described.

3. In a driving and coasting mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism extending within the hub; external threads upon the part extending within the hub; a part of the hub adapted to be engaged by a clutch-ring; an expansible clutch-ring; and a clutch-nut upon the threaded portion of the driving mechanism whereby the clutch-ring is expanded into engagement with the hub, substantially as described.

4. In a driving and coasting mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism extending within the hub; external threads upon the part extending within the hub; conical surfaces A^4 within the hub adapted to be engaged by a clutch-ring; the expansible clutch-ring B^7; and the clutch-nut C upon the threaded portion of the driving mechanism, having conical and cylindrical surfaces c^3, c^4, whereby the clutch-ring is expanded so as to engage the hub, and is supported when out of engagement therewith, substantially as described.

5. In a driving and coasting mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism extending within the hub; external threads upon the part extending within the hub; a part of the hub adapted to be engaged by a clutch-ring; an expansible clutch-ring comprising shoes; a clutch-nut upon the threaded portion of the driving mechanism, whereby the clutch-ring is expanded so as to engage the hub, substantially as described.

6. In a driving and coasting mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism extending within the hub; surfaces upon the hub adapted to be engaged by an expansible clutch-ring; an expansible clutch-ring; a clutch-nut upon the threaded portion of the driving mechanism, whereby the clutch-ring is expanded to engage the hub on forward driving; and projections from the nut whereby the clutch-ring is prevented from rotating with reference to the nut, substantially as described.

7. In a coaster and brake mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism having a part extending within the hub and having threads thereon; a part of the hub adapted to be engaged by a clutch-ring; an expansible clutch-ring; a clutch-nut upon the threaded portion of the driving mechanism, whereby the clutch-ring is expanded so as to engage the hub in forward driving, and a brake mechanism adapted to engage the hub on back pedaling, substantially as described.

8. In a coaster and brake mechanism, the combination of a hollow hub having bearings at its ends; a driving mechanism having a part extending within the hub; and having threads thereon; a part of the hub adapted to be engaged by a clutch-ring, and also a part adapted to be engaged by a brake-clutch; a block H within the hub secured against turning; projections h' upon the surfaces of the block H; brake-shoes J notched to receive the projections h', upon the block H; teeth h upon the block H; the spring j; and a clutch-nut upon the threaded portion of the driving mechanism, having the tooth c' on its side, and adapted in forward pedaling to expand the clutch-ring so as to engage the hub, and on back pedaling both to expand the clutch-shoes, and to turn them upon the projections h' so as to brake the hub, substantially as described.

708,202. CUSHION-FRAME FOR BICYCLES. FRANK B. CASE, Rochester, N. Y., assignor to Riggs-Spencer Company, Rochester, N. Y., a Corporation of New York. Filed Aug. 6, 1901. Serial No. 71,088. (No model.)

Claim.—1. In a bicycle, the combination of a rigid front frame, a rear-wheel fork flexibly connected thereto at or near the crank-hanger, a brace flexibly connected to the rear portion of the front frame and comprising as one section concentric tubes, a tube fitting air-tight the space between said concentric tubes whereby the two sections may telescope one into the other, a spring within said tubes for extending said sections with reference to each other, a collar upon one tube of each section, and a spring between said collars tending to cause said sections to telescope one into the other when they are extended beyond the normal limit, substantially as described.

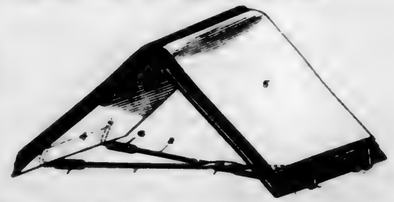
2. In a bicycle, the combination of a rigid front frame, a rear-wheel fork flexibly connected to said front frame at or near the crank-hanger, a brace flexibly connected with the rear portion of the rear-wheel fork and having a section flexibly connected to the upper rear portion of the front frame, said brace comprising a cap having two concentric tubes, the inside one being longer than the other, and having an outside collar, and another section having a tube provided with an internal collar and fitting air-tight the space between the said concentric tubes, a coiled spring within the second section and extending within the inner tube of the first section for extending the two sections, and a second coiled spring between said collars for contracting the sections when they are extended beyond the normal limit, substantially as described.

3. In a bicycle, the combination of a rigid front frame, a crank-hanger hinged thereto, a rear-wheel fork rigidly connected to the crank-hanger, a brace flexibly connected to the rear portion of the front frame and to the rear-wheel fork and comprising as one section concentric tubes, and as the other section a tube fitting air-tight the space between the said concentric tubes, said sections containing a spring adapted to extend said sections and a spring for contracting said sections when they are extended beyond the normal limit, substantially as described.

4. In a bicycle, the combination of a rigid front frame, a crank-hanger hinged thereto, a rear-wheel fork rigidly connected to the crank-hanger, a brace flexibly connected to the rear portion of the front frame and to the rear-wheel fork and comprising as one section concentric tubes, a tube fitting air-tight the space between said concentric tubes whereby the two sections may telescope one into the other, a coiled spring within said tubes for extending said sections with reference to each other, a collar upon one tube of each section, and a spring between said collars tending to cause said sections to telescope one into the other when they are extended beyond the normal limit, substantially as described.

5. In a bicycle, the combination of a rigid front frame, a crank-hanger hinged thereto, a rear-wheel fork rigidly connected to the crank-hanger, a brace flexibly connected with the rear portion of the rear-wheel fork and having a section flexibly connected to the upper rear portion of the front frame, said brace comprising as one section a cap having two concentric tubes, the inside one being longer than the other and having an outside collar, and another section having a tube provided with an internal collar and fitting air-tight the space between the said concentric tubes, a coiled spring within the second section and extending within the inner tube of the first section for extending the two sections, and a second coiled spring between said collars for contracting the sections when they are extended beyond the normal limit, substantially as described.

708,203. COPY-HOLDER. THOMAS P. CHANDLER, Rochester, Pa. Filed Mar. 17, 1902. Serial No. 98,627. (No model.)



Claim.—1. As an article of manufacture, a copy-holder, comprising two arms crossing each other and pivotally joined, and turned-up end portions on each arm, substantially as set forth.

2. As an article of manufacture, a copy-holder, comprising two arms crossing each other and each having turned-up end portions, and rests or supports on each arm, substantially as set forth.

3. As an article of manufacture, a copy-holder, comprising two arms crossing each other and pivotally joined, each provided with turned-up end portions, and rests or supports on each arm, substantially as set forth.

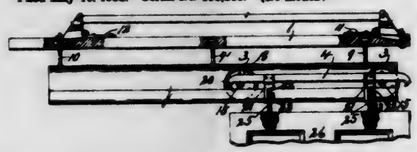
708,204. CASTER. GEORGE D. CLARK, Plainville, Conn. Filed Dec. 24, 1901. Serial No. 87,063. (No model.)

Claim.—1. In a caster, a sheet-metal frame comprising a solid top, a perforation therein to form an upper bearing for a pintle the sides and back of said top being bent down and contracted to form a lower bearing for the pintle, wheel-supporting horns extending downwardly from the solid top and forwardly from the depressed sides thereof.

2. In a caster, a sheet-metal frame comprising a solid top, a perforation therein to form an upper bearing for a pintle the sides and back of said top being bent to form a lower bearing for the pintle, wheel-supporting horns extending downwardly from the solid top and forwardly from the depressed sides thereof, and corrugations between the depressed sides and said horns, said corrugations being deeper at the bottom than at the top.

3. In a caster, a sheet-metal frame comprising a solid top, a perforation therein to form an upper bearing for a pintle, the sides and back of said top being bent to form a lower bearing for the pintle, wheel-supporting horns extending downwardly from the solid top and forwardly from the depressed sides thereof, and a bushing secured in place by the back and sides of said top portion.

708,205. DOOR-HANGER. JOSEPH F. CLIFT, Syracuse, N. Y. Filed May 10, 1902. Serial No. 106,808. (No model.)



Claim.—1. In a door-hanger, the combination with a track, rocking members located at the ends of the track, a link connecting the members, one of said members being connected to one end of the track, means for rocking the other member, separate means for raising and lowering the other end of the track, and a carriage for the door mounted on the track.

2. In a door-hanger, a bell-crank, a track having one end connected to one arm of the bell-crank, means at the other end of the track connected to the other arm of the bell-crank for rocking the bell-crank, and a carriage for the door mounted on the track and separate means for adjusting said other end of the track.

3. In a door-hanger, two bell-cranks and supports therefor, a link connecting corresponding arms of the bell-cranks, a track having one end connected to the adjacent bell-crank and raised and lowered thereby, adjusting means connected to rock the other bell-crank, separate adjusting means for the other end of the track, and a carriage for the door mounted on the track.

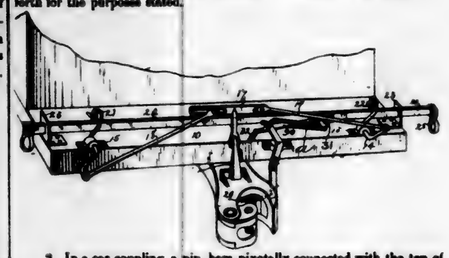
4. In a door-hanger, a fixed support and a track beneath the support, in combination with a bell-crank hinged to the support at one end of the track and having one arm adjustably connected to the opposite end of the track for raising and lowering the same, adjusting means connected to the other arm of the bell-crank for rocking the same, separate means for adjusting said one end of the track vertically, and a carriage for the door mounted on the track.

5. In a door-hanger, the combination of a support, a track, bell-cranks pivotally mounted on the support, at opposite ends of the track, a link connecting corresponding arms to the bell-cranks, adjusting-screws connected to the other arms and engaged respectively with the support and track, separate means engaged with the support and track for adjusting the same vertically, and a carriage for the door mounted on the track.

6. A door-hanger, the combination of a support, levers mounted on the support, an adjusting-screw connecting one of the levers to the support for rocking the lever, a link connecting the levers to transmit rocking motion from one to the other, a track having one end adjustably connected to the other lever and its other end adjustably connected to the support in proximity to the former adjusting-screw, and a carriage for the door mounted on the track.

708,206. AUTOMATIC CAR-COUPLING. SOLOMON GEE and GEO. W. WARNER, Granger, Iowa. Filed Nov. 20, 1901. Serial No. 83,262. (No model.)

Claim.—1. In a car-coupling, two crank-shafts in bearings fixed to the side portions of a car-platform, a pin, two bars pivotally connected with the top of the pin and means for jointly actuating the crank-shafts for lifting the pin, arranged and combined to operate in the manner set forth for the purposes stated.

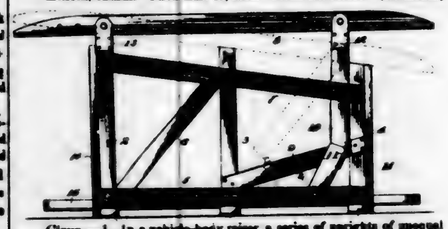


2. In a car-coupling, a pin, bars pivotally connected with the top of the pin, crank-shafts mounted on the platform and connected with the ends of said bars, a straight bar slidably mounted on the platform, bridles projecting vertically from the sliding bar to admit the inner ends of the crank-shafts and means for moving the slidable bar, arranged and combined to operate in the manner set forth, for the purposes stated.

3. In a car-coupling, a draw-head connected with the platform at the end of a car, a spring-actuated elbow-shaped lever pivoted to the platform and one end of the lever extended through a slot in the draw-head, a bar slidably mounted on the platform to extend from one side to the other, bridles projecting upward from the slidable bar, crank-shafts mounted on the platform and their inner arms extended through said bridles, a bar pivotally connected with each outer arm of the crank-shafts and a pin pivotally connected with the ends of said bars, arranged and combined to operate in the manner set forth for the purposes stated.

4. In a car-coupling, a pin-operating mechanism comprising a pin, two bars pivotally connected with the top of the pin to extend laterally in reverse ways, crank-shafts mounted on the car-platform and their outer ends pivotally connected with the ends of said bars, a bar mounted on the platform to slide in reverse ways and provided with bridles projecting upward therefrom to be traversed by the inner ends of the crank-shafts, a shoulder on the slidable bar, a spring-actuated elbow-shaped lever fulcrumed to the platform and one end extended through a slot in the draw-head and a pawl pivoted to its other end to engage the shoulder on the slidable bar, all arranged and combined to operate in the manner set forth for the purposes stated.

708,207. VEHICLE-BODY RAISER. JAMES E. CRYDERMAN, Edmonton, Canada. Filed Mar. 15, 1902. Serial No. 98,413. (No model.)



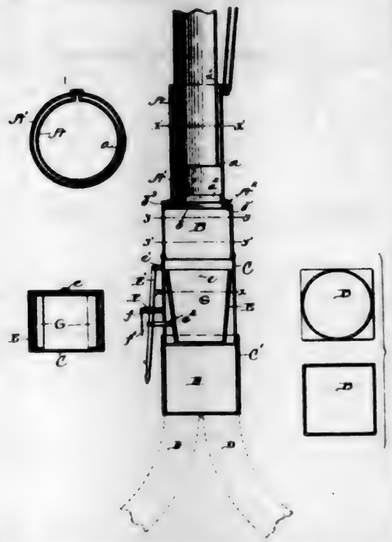
Claim.—1. In a vehicle-body raiser, a series of uprights of unequal length on each side forming a driveway, a lever adjustably pivoted to each of the highest uprights and supporting-standards comprising two sections hinged together, the meeting ends of said sections being oppositely beveled to swing past a line drawn through the pivots of the opposite ends of said sections.

2. In a vehicle-body raiser, a frame suitably supported, said frame being portable, a series of uprights of unequal length, a lever pivoted to the highest upright of each series, supporting-standards pivoted to each lever, the said standards swinging into engagement with the short uprights on each side whereby the weight is supported, as and for the purpose described.

3. In a vehicle-body raiser, a portable structure, levers pivoted thereto, said levers being adjustable to project a greater or less degree beyond the lower end of the structure, standards pivoted to the levers; said standards being in two sections having oppositely-beveled meeting ends, hinges connecting the sections, the said standards being so positioned as to contact with the end upright of the structure, as and for the purpose described.

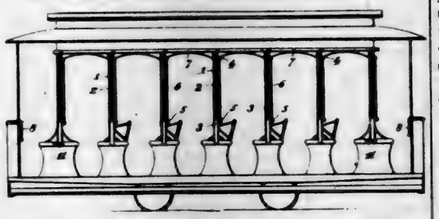
708,208. GRAIN-SPOUT. WILLIAM D. DOZIER, Peoria, Ill. Filed Nov. 18, 1899. Renewed July 26, 1902. Serial No. 117,203. (No model.)

Claim.—1. A device of the character described comprising the telescopic sections A, A', hood B, rotatably mounted on the section A', sections C, C', the bifurcated sections D, D, an equaliser E, pivotally mounted in the section C, means for adjusting the equaliser, and means for elevating the structure, substantially as described.



2. A device of the character described, comprising the telescopic sections A, A', splined together, hood B, rotatably mounted on the section A', bifurcated sections D, D, a section intermediate the hood and bifurcated sections, an equaliser adjustably mounted in said intermediate section, and means for securing the equaliser in its adjusted positions, substantially as described.

708,209. SIDE GUARD FOR CARS. JAMES H. DONNELLY, Philadelphia, Pa., assignor of one-half to William W. Ruley, Philadelphia, Pa. Filed May 15, 1902. Serial No. 107,672. (No model.)



Claim.—1. A side guard for cars, comprising a series of guard-arms, a series of independent bell-cranks, connections between said guard-arms and bell-cranks, and a reciprocating connecting-rod for said bell-cranks, substantially as described.

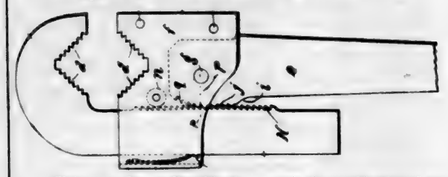
2. A side guard for cars, comprising a series of guard-arms pivoted to the uprights of the car, a series of bell-cranks also pivoted to said uprights, connecting rods or links for said guard-arms and bell-cranks, and a reciprocating connecting-bar for said bell-cranks, whereby said guard-arms and bell-cranks are movable simultaneously to open and close the entrances to the car, substantially as described.

3. A side guard for cars, comprising a series of guard-arms pivoted to the uprights of the car, a series of bell-cranks also pivoted to said uprights, connecting rods or links for said guard-arms and bell-cranks, a reciprocating connecting-bar for said bell-cranks, whereby said guard-arms and bell-cranks are movable simultaneously to open and close the entrances to the car, and catches for holding said parts in open position, substantially as described.

4. A side guard for cars, comprising a series of guard-arms pivotally secured to the car by the handle-bar fastenings, a series of bell-cranks also pivotally secured to the car by the said fastenings, connecting rods or links for said guard-arms and bell-cranks, and a reciprocating connecting-bar for said bell-cranks, whereby all of said bell-cranks and guard-arms are movable simultaneously to open and close the entrances to the car, substantially as described.

5. A side guard for cars, comprising a series of guard-arms pivotally secured to the car by the handle-bar fastenings, a series of bell-cranks also pivotally secured to the car by said fastenings, connecting rods or links for said guard-arms and bell-cranks, and a reciprocating connecting-bar for said bell-cranks, whereby all of said bell-cranks and guard-arms are movable simultaneously to open and close the entrances to the car, the free ends of said guard-arms when in the closed position adapted to engage the adjacent handle-bars, substantially as described.

708,210. WRENCH. AXEL DAHL, North Tarrytown, N. Y. Filed Apr. 30, 1902. Serial No. 105,264. (No model.)

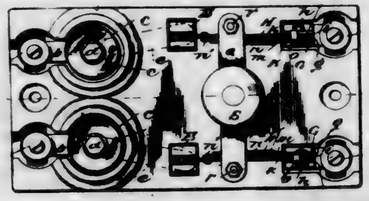


Claim.—1. In an adjustable pipe-wrench, the combination of two jaws each having a notched and serrated face formed in two parts having angular relation to each other adapting the two jaws to have biting effect at four points in the circumference of the pipe, the lever pivoted at one end in the space between the cheeks of one of said jaws, a shank of the other jaw sliding in the said space, clutching-teeth on said shank and lever respectively adapted to be unclutched for adjusting the jaws and a spring for normally maintaining the clutched condition of the shank and lever.

2. In an adjustable pipe-wrench, the combination of two jaws each having a serrated face adapted to have biting effect on the pipe, the lever pivoted at one end in the space between the cheeks of one of the jaws, a shank of the other jaw sliding in the said space, clutching-teeth on said shank and lever respectively adapted to be unclutched for adjusting the jaws, a spring for normally maintaining the clutched condition of the shank and lever and a fulcrum for the jaw-shank located in the space between the cheeks of the jaw wherein the lever is pivoted and in advance of the pivot to facilitate unclutching said jaws.

3. In an adjustable pipe-wrench, the combination of two jaws each having a serrated face adapted to have biting effect on the pipe, the lever pivoted at one end in the space between the cheeks of one of the jaws, a shank of the other jaw sliding in said space, clutching-teeth on said shank and lever respectively adapted to be unclutched for adjusting the jaws, a spring for normally maintaining the clutched condition of the shank and lever and a fulcrum for the said shank located in the space between the cheeks of the jaw wherein the lever is pivoted and in advance of the pivot, the toothed face of the lever being reduced radially to the pivot between the transverse axial line of the lever and the fulcrum to favor unclutching the teeth.

708,211. ELECTRIC SNAP-SWITCH. LOUIS W. DOWNES, Providence, R. I. Filed May 3, 1902. Serial No. 105,613. (No model.)

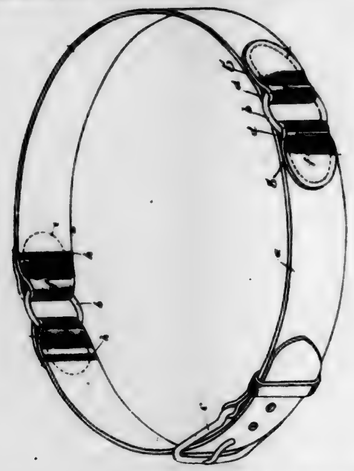


Claim.—1. In an electric snap-switch, two circuit-terminals, a switch-blade pivoted to one of the terminals and adapted to be moved on its pivot into and out of engagement with the other terminal, an actuating-lever normally extending along one side of the switch-blade and fulcrumed at one end on the pivot of said blade, a spring connected at one end to the lever and at the other end to the switch-blade, a lug on the pivoted end of the lever, and a tooth or projection on the pivoted end of the blade which the lug is adapted to engage after the actuating-lever has been moved a predetermined distance and the spring thereby put under tension.

2. In an electric snap-switch, two circuit-terminals, a switch-blade pivoted to one of the terminals and adapted to be moved on its pivot into and out of engagement with the other terminal, an actuating-lever normally extending along one side of the switch-blade and fulcrumed at one end on the pivot of said blade, a spiral spring connected at one end to the blade at a point remote from its pivot, a finger on the actuating-lever adjacent to its fulcrum said finger projecting into the other end of the spiral spring, a lug on the pivoted end of the lever projecting over the edge of the switch-blade, and a tooth or projection on the pivoted end of the blade which the lug is adapted to engage after the actuating-lever has been moved a predetermined distance and the spring thereby put under tension.

3. In a double electric snap-switch, two single switches each comprising two circuit-terminals, a switch-blade pivoted to one of the terminals and adapted to be moved on its pivot into and out of engagement with the other terminal, an actuating-lever normally extending along one side of the switch-blade and fulcrumed at one end on the pivot of said blade, a spring connected at one end to the lever and at its other end to the switch-blade, a lug on the pivoted end of the lever, and a tooth or projection on the pivoted end of the blade which the lug is adapted to engage after the actuating-lever has been moved a predetermined distance and the spring thereby put under tension; angular extensions at the free end of the actuating-levers of the several switches, and a bar of non-conducting material connecting and secured to said angular extensions so that the actuating-levers move together.

708,212. LEATHER BELT. JAMES I. FABEY, Boston, Mass. Filed Jan. 4, 1901. Serial No. 42,169. (No model.)

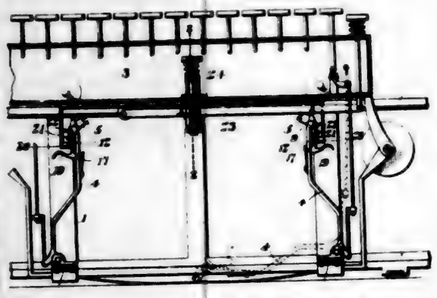


Claim.—1. A belt consisting of a plurality of main straps of uniform thickness throughout their entire length and forming the body portion, combined with a plurality of connecting-rings, and straps forming loops embracing said rings for connecting the main straps together, said loops having ends of unequal length, the shorter ends abutting against the ends of the main straps and the longer ends overlapping the outer face of the main straps, said loops suitably attached to the main straps and of substantially the same thickness.

2. A belt consisting of a plurality of main straps forming the body portion, combined with a plurality of connecting-rings, and straps forming loops embracing said rings for connecting the main straps together, said loops having ends of unequal length, the shorter ends abutting against the ends of the main straps and the longer ends overlapping the outer face of the main straps, said loops suitably attached to the main straps, substantially as herein shown and described.

708,213. TYPE-WRITING MACHINE. ROBERT J. FISHER, Athens, Tenn., assignor to the Fisher Book Typewriter Company, Cleveland, Ohio, a Corporation of Delaware. Filed Aug. 29, 1900. Serial No. 28,419. (No model.)

Claim.—1. In a type-writing machine, the combination with the type-bar, of a pivotal type-head carried by the type-bar and having a cam-ear formed with an arcuate bearing-face, a trigger carried by the type-bar and having a shifter element cooperating with said bearing-face, and means for actuating said trigger.



2. In a type-writing machine, the combination with the type-bar, and the type-head pivoted thereto, of a device carried by the type-bar for shifting the type-head to either of two positions by engaging with said head at opposite sides of its pivotal point.

3. In a type-writing machine, the combination with the type-bar, and the type-head pivoted thereto, of a device carried by the type-bar for shifting the type-head to either of two positions and locking the same in each position, said operations being effected by direct engagement with the head at opposite sides of its pivotal point.

4. In a type-writing machine, the combination with the type-bar, the type-head pivoted thereto, and means for limiting the swinging movement of the type-head beyond either of two positions, of a device carried by the type-bar for positively shifting the head to and locking the same in either position.

5. In a type-writing machine, the combination with the type-bar, and the type-head pivoted thereto, of a device carried by the type-bar directly engaging with the type-head for shifting the same to and locking said type-head in either of two positions, and means for limiting the movement of said device so as to hold it in engagement.

6. In a type-writing machine, the combination with the type-bar, and the shiftable type-head, of a device carried by the type-bar to shift the type-head to either of two positions and to lock the same, and separate trips arranged at all times outside of the path of the type-head and adapted to be brought alternately in contact with the device to cause the shifting of the type-head to one position and to restore said head to its normal position.

7. In a type-writing machine, the combination with the type-bar, and the pivoted type-head carried thereby and provided with a portion projecting beyond the pivotal point, of a device carried by the type-bar and having a shifting finger engaging with the type-head and adapted to be transferred to opposite sides of the pivot of the head to shift the same into either of two positions.

8. In a type-writing machine, the combination with the type-bar, and the pivoted type-head carried thereby and provided with a portion projecting beyond the pivotal point, of a device carried by the type-bar and having a shifting-finger engaging with the type-head and adapted to be transferred to opposite sides of the pivot of the head to shift the same into either of two positions, a resetting-arm and a tripping-tail carried by the device, and a double trip engaging with the tripping-tail and the resetting-arm.

9. In a type-writing machine, the combination with the type-bar, and a movable type-head mounted thereon and adapted to be shifted to either of two positions, of a single device carried by the type-bar and engaging with the type-head for positively shifting the head to and locking the same in each position.

10. In a type-writing machine, the combination with the type-bar, and a movable type-head mounted thereon and adapted to be shifted to either of two positions, of a single spring-actuated device carried by the type-bar and engaging with the type-head for positively shifting the head to and locking the same in each position.

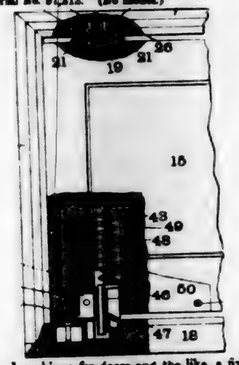
11. In a type-writing machine, the combination with the type-bar and a type-head pivoted thereto, of a device mounted on the type-bar independent of the type-head, but adapted to engage the same to shift it to either of two operative positions and also lock the same in each position.

12. In a type-writing machine, the combination with the type-bar, and a type-head pivoted thereto, of a device pivoted on the type-bar, independent of the type-head, but adapted to engage the same to shift it to either of two operative positions and also lock the same in each position.

13. The combination with the type-bar, and the type-head pivoted thereto, of a single device pivoted on the type-bar, independent of the type-head, but adapted to engage the same to shift the type-head to either of two positions and serve as a lock for the said head in each position, and a spring acting against the said device for the purposes described.

14. The combination with the type-bar, and the shiftable type-head pivoted thereto, of a single device carried by the type-bar, independent of the type-head, and constituting a combined shifting and locking means for the type-head, to shift the latter to either of two positions and lock the same in each position, and a spring for the said device.

08,214. HINGE. CHARLES H. FOSTER, Omaha, Nebr. Filed Mar. 8, 1902. Serial No. 97,212. (No model.)



Claim.—1. In a hinge for doors and the like, a fixed part, a movable part, a beveled track carried by one of said parts, and a member carried by the other of said parts and traveling on said track, said track and member being arranged to force the said movable part toward the rear.

2. In a hinge for doors and the like, a fixed part, a movable part, a beveled track carried by one of said parts, and a conical wheel carried by the other of said parts and traveling on said track, said track and conical wheel being arranged to force the said movable part toward the rear.

3. In a hinge for doors and the like, a fixed part, a movable part, one of said parts being provided with a pair of bearings and the other with a pair of bearing-pins, a beveled track carried by one of said parts, and a conical wheel carried by the other of said parts and traveling on said track, said track and wheel being arranged to force the said movable part toward the rear.

4. In a hinge for doors and the like, a fixed part, a pair of bearings carried by said fixed part, a movable part, a pair of bearing-pins carried by said movable part, a beveled track carried by said fixed part, and a conical wheel carried by said movable part and traveling on said track, said track and wheel being arranged to force the said movable part toward the rear.

5. In a hinge for doors and the like, a fixed part, a movable part, a beveled track carried by one of said parts, a member slidingly mounted on the other of said parts, a conical roller carried by said member and traveling on said track, said track and roller being arranged to force the said movable part toward the rear and a spring for forcing said roller against said track.

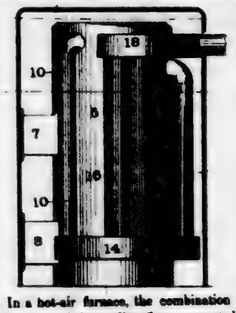
6. In a hinge for doors and the like, a fixed part, a movable part, a track carried by one of said parts, a yieldingly-mounted member carried by the other of said parts and traveling on said track, and a pair of inclines at the ends of said track for contacting with the part carrying said yieldingly-mounted member.

7. In a hinge for doors and the like, a fixed part, a movable part, a track carried by one of said parts, a yieldingly-mounted member carried by the other of said parts and traveling on said track, a pair of inclines at the ends of said track for contacting with the part carrying said yieldingly-mounted member, and a pair of stops at the ends of said inclines for limiting the movement of said movable part.

8. In a hinge for doors and the like, a fixed part, and a movable part, one of said parts being provided with a pair of bearings, a pair of intersecting curved guideways extending therefrom, and a pair of auxiliary guideways adjacent thereto, and the other of said parts being provided with a pair of bearing-posts cooperating with said bearings and traveling in said intersecting guideways, and a pair of legs adjacent to said posts and traveling in said auxiliary guideways.

9. The combination with a door, of an upper hinge consisting of a fixed part and a movable part, one of said parts being provided with a pair of projections and the other of said parts being provided with a pair of inclined rub-strips for contacting with said projections, and means for raising said door when it is opened.

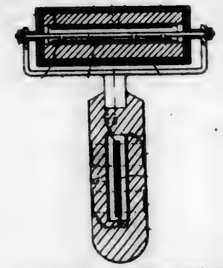
708,215. HOT-AIR FURNACE. CHARLES H. FOSTER, Omaha, Nebr. Filed Mar. 13, 1902. Serial No. 98,070. (No model.)



Claim.—1. In a hot-air furnace, the combination with a combustion-chamber, of two sets of descending flues connected with said combustion-chamber, a base-flue connecting the pipes of one of said sets, a second base-flue connecting the pipes of the other of said sets, ascending flues connected with said base-flues, a conduit connecting said ascending flues, and an outlet leading from said conduit.

2. In a hot-air furnace, the combination with a combustion-chamber, of a pair of long descending flues connected therewith, a pair of short descending flues also connected with said combustion-chamber, a pair of base-flues each connecting a long and a short descending flue, a pair of ascending flues each connected with one of said base-flues at a point nearer to the long than to the short descending flue, a conduit connecting said ascending flues and passing above said short descending flues, and an outlet leading from said conduit.

708,216. ELECTROMEDICAL APPLIANCE. JONATHAN O. POWLER, Jr., New York, N. Y., assignor to John W. Gibbs, New York, N. Y. Filed Mar. 30, 1901. Serial No. 53,644. (No model.)



Claim.—1. In a device for applying electricity, the combination of a hollow roller-shell, a handle therefor, and means for generating a current of electricity within said roller-shell, and also means for connecting the said electricity-generator with the shell, and an induction-coil located in said handle.

2. In a device for applying electricity, the combination of a roller, a handle therefor, and means for generating electricity mechanically, said electricity-generating means being constructed and arranged to be operated by the motion of the roller, and an induction-coil located in said handle.

3. In a device for applying electricity, the combination of a hollow roller-shell, a handle therefor, and means for generating a current of electricity within said roller-shell, and also means for connecting said electricity-generator with the shell, and an induction-coil located in said handle.

4. In a device for applying electricity, the combination of a roller, a handle therefor, and means for generating a series of induced currents of electricity mechanically, contained within said shell, said electricity-generating means being constructed and arranged to be operated by the motion of the roller, and an induction-coil located in said handle.

5. In a device for applying electricity, the combination with a movable roller-shell, and a handle therefor, of a relatively stationary part forming one member of the electricity-generating system, and of another mem

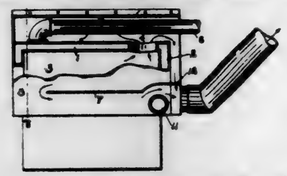
ber of the generator of electricity secured to said shell, to cause the operation of the generator of electricity by the motion of the roller, and an induction-coil located in said handle.

6. In a device for applying electricity, a roller, a handle therefor, a coil of wire contained within the roller, and means to set up in said coil an induced current of electricity by the motion of the roller, and an induction-coil located in said handle.

7. In a device for applying electricity, the combination of a roller, and a handle therefor, and a coil of wire located adjacent to the roller, and means to set up a series of induced currents of electricity in said coil by the motion of the roller, and an induction-coil located in said handle.

8. In a device for applying electricity, a roller, a handle therefor, a coil of wire, and means to set up in said coil an induced current of electricity by the motion of the roller, and an induction-coil located in said handle.

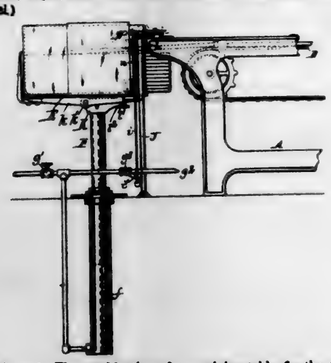
708,217. **WATER-HEATING FURNACE.** HUGH A. FRASER, Sarnia, Canada. Filed Apr. 14, 1902. Serial No. 102,797. (No model.)



Claim.—1. A water-heating furnace comprising in combination an inner water-containing shell of inverted-U section; an outer casing inclosing said shell; an opening through the top of the water-containing shell near its rear end, connecting the combustion-chamber with the space between the shell and the casing; a horizontal deflecting-plate extending around the lower part of the shell and connecting the shell and casing; openings near the front ends of said deflecting-plate; a smoke-pipe communicating with the interior of the casing below said deflecting-plate; and openings in the deflecting-plate in proximity to the smoke-pipe, for the purposes set forth.

2. In a furnace the combination of a combustion-chamber inclosed by an inverted water-containing shell of substantially U-shaped section having a water-containing end, said shell and end being formed in one piece; an opening for the passage of hot gases from the combustion-chamber through the upper part of said shell near its rear end; a distributing-pipe extending above said opening; an outer casing inclosing the distributing-pipe and shell; a horizontal deflecting-partition near the lower part of said shell, connecting the shell and casing and extending along the sides and back of the shell; and openings for the passage of hot gases near the front ends of said partition; all arranged and operating for the purposes set forth.

708,218. **APPARATUS FOR PACKING OIL-CAKES.** ALFRED W FRENCH, Piqua, Ohio. Filed Nov. 30, 1900. Serial No. 38,127. (No model.)



Claim.—1. The combination of a receiving-table for the trimmed cakes, means for holding a bag distended on said table, a support for said table, and a horizontal pivotal joint connecting said table with said support, whereby the table can be swung from its horizontal receiving position to its upright discharging position, substantially as set forth.

2. The combination of a receiving-table having an abutment, means for holding a bag distended on said table, a head on which said table is supported, a horizontal pivotal joint connecting said table with said head, and a stop provided on said head and supporting the table in its horizontal position, substantially as set forth.

3. The combination with a cake-trimming machine, of a receiving-table for the trimmed cakes, means for holding a bag distended on said table, and a support to which said table is attached by a pivotal connection which allows the table to be tilted for removing the pile of cakes and bag, substantially as set forth.

4. The combination with a cake-trimming machine, of a receiving-table for the trimmed cakes provided with an abutment at one end, means for holding a bag distended on said table, a support to which said table is attached by a transverse pivotal connection which allows the table to be tilted, and means for lowering said table-support automatically, substantially as set forth.

5. The combination of a receiving-table, a support on which the same is pivoted, and two separate bag-holding devices arranged lengthwise upon the table on opposite sides thereof, substantially as set forth.

6. The combination of a pivoted receiving-table, and two holding devices arranged lengthwise upon the table on opposite sides thereof and pivoted at their front ends to the table, substantially as set forth.

7. The combination with the receiving-table, of two bag-holders arranged lengthwise upon the table on opposite sides thereof and provided at their front ends with vertical pivotal devices by which the holders are detachably connected to the table, substantially as set forth.

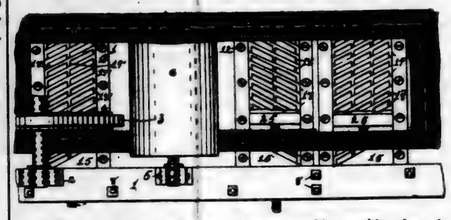
8. The combination with the receiving-table provided at its rear end with an abutment, of two bag-holders arranged lengthwise upon the table on opposite sides thereof and connected with the table at their front ends by vertical pivotal devices, substantially as set forth.

9. The combination of means for holding a bag distended, a receiving-table which supports said bag-holding means, means for feeding the cakes successively into the bag, and means for intermittently moving said table in a direction transversely of the direction of movement of the cakes by the feeding means, said receiving-table extending beneath the bag on said holder and supporting the cakes and the bag, substantially as set forth.

10. The combination of a receiving-table, and means for holding a bag thereon, said means being movable with said bag away from said table, substantially as set forth.

11. The combination of a tilting receiving-table, and a bag-holding means detachably connected with said table whereby the filled bag can be removed from the table, substantially as set forth.

708,219. **SUCTION-BOX COVER FOR PAPER-MAKING MACHINES.** WILLIAM M. GILBERT, THEODORE M. GILBERT, and WILLIAM C. HAHN, Neenah, Wis. Filed July 2, 1902. Serial No. 114,160. (No model.)



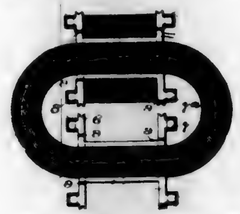
Claim.—1. A suction box cover for paper-making machines formed of a series of blocks having grooves therein of such form that when said blocks are assembled together side by side with their ends upon opposite sides of the suction-box, said grooves form a series of apertures through said cover having parallel sides and ends which are of greater length than width, suitably-shaped end pieces for each end of said cover, and means for holding said blocks and end pieces in position over the suction-box, substantially as described.

2. A suction-box cover for paper-making machines formed of a series of blocks having grooves therein of such form that when said blocks are assembled together side by side diagonally across said box with their ends upon opposite sides thereof, said grooves form a series of apertures through said cover of a rhomboidal form, suitably-shaped end pieces for each end of the cover, and means for holding said blocks and end pieces in position over said suction-box, substantially as set forth.

3. A suction-box cover for paper-making machines formed of a series of blocks having grooves therein of such form that when said blocks are assembled together side by side with their ends upon opposite sides of the suction-box, said grooves form a series of apertures through said cover having parallel sides and ends which are of greater length than width, suitably-shaped end pieces for each end of said cover, a tenon upon opposite ends of each block and end piece, and a groove upon opposite sides of the suction-box above the ends thereof for receiving said tenons and holding said blocks and end pieces in position therein, substantially as described.

4. A suction-box cover for paper-making machines formed of a series of blocks having grooves therein of such form that when said blocks are assembled together side by side with their ends upon opposite sides of the suction-box, said grooves form a series of apertures through said cover having parallel sides and ends which are of greater length than width, suitably-shaped end pieces for each end of the cover, a tenon upon the opposite ends of each block and end piece, a rail secured upon the top of the opposite longitudinal side walls of the suction-box, and a groove at the meeting edges of said rails and side walls for receiving said tenons and holding said blocks and end pieces in position over the suction-box, substantially as set forth.

708,220. **MEANS FOR WINDING CONVERTERS OR LIKE ARTICLES.** EDWIN R. GILL, New York, N. Y., assignor to Invention Developing Company, a Corporation of New Jersey. Filed Mar. 30, 1899. Serial No. 711,060. (No model.)



Claim.—1. As an article of manufacture, an electrical apparatus with a virtually-closed magnetic circuit having a practically straight portion, a divisible spool on said straight portion, and terminals for the conductors on said spool, said terminals serving also to fasten the parts of said spool together.

2. As an article of manufacture for use with electrical apparatus, a divisible insulating-spool having means for fastening the end of a conductor thereto.

3. As an article of manufacture for use with electrical apparatus, a divisible insulating-spool having terminal conducting-knobs on the outside of the flanges thereof for fastening the ends of the wires to be wound thereon.

4. As an article of manufacture for use with electric apparatus, a divisible insulating-spool having half-knobs on its half-flanges adapted to come together as described, and metallic caps fitting over said half-knobs in pairs when juxtaposed.

5. As an article of manufacture for use with electric apparatus, a divisible insulating-spool having half-knobs on its half-flanges, threaded and adapted to come together as described, and metallic caps adapted to screw onto said half-knobs in pairs when juxtaposed.

6. As an article of manufacture for use with electric apparatus, a divisible insulating-spool having half-knobs on its half-flanges, threaded and adapted to come together as described, metallic caps adapted to screw onto said half-knobs in pairs when juxtaposed, and a circumferential groove on one of said flanges.

7. In a converter, a closed-circuit subdivided core and two half-shells of iron applied to the two sides of said core for confining said laminations.

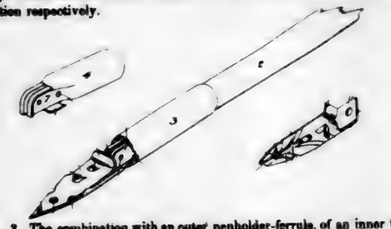
8. In a converter, a core composed of iron wire wound into shape, and two half-shells of iron applied to the two sides of said core to confine said wire.

9. In a converter, a closed magnetic circuit having a straight portion, a divisible spool revolubly mounted on said straight portion, metallic terminals on the flanges of said spool for holding said spool portions together, and primary and secondary windings on said spool terminating in said metallic terminals.

708,221. **FOUNTAIN-PEN.** ROBERT T. GILLESPIE, Rochester, Pa. Filed June 26, 1901. Serial No. 66,080. (No model.)

Claim.—1. A penholder provided with means for holding the pen, a pivoted lid provided with bearing-shoulders adapted to be raised from and to be closed upon and to form with the pen an ink-holding cavity, and a spring-controlled dog adapted to bear against the shoulders and to hold the lid in a lowered or raised position.

2. A penholder provided with an inner ferrule and adapted to form with the ferrule of the penholder a pen-retaining socket, a lid pivotally mounted in the inner ferrule provided with shoulders, and a spring-controlled dog adapted to bear against shoulders upon the lid angularly arranged with relation to each other, and to hold it in a lowered or raised position respectively.



3. The combination with an outer penholder-ferrule, of an inner ferrule, a lid pivotally mounted in the inner ferrule provided with a shoulder, a spring-controlled dog adapted to bear against the shoulder of the lid, and means for connecting the outer and inner ferrules.

4. The combination of an outer penholder-ferrule and an inner ferrule provided with forwardly-extending cheeks, an ink-retaining lid pivotally mounted between the cheeks and provided with shoulders, a spring-controlled dog adapted to bear against the shoulder, and means for securing the outer and inner ferrules together.

5. A cylindrical ferrule adapted to be inserted in the ferrule of the penholder, having forwardly-extending cheeks, a lid pivotally mounted between the cheeks provided with shoulders, and a spring-controlled dog mounted within the ferrule and adapted to bear against the shoulders and to hold the lid in a lowered or raised position respectively with relation to the pen-point.

6. A cylindrical ferrule adapted to be inserted within the ferrule of a penholder having outwardly-extending cheeks, a lid pivotally mounted between the cheeks provided with shoulders, perforations, corrugations and raised portions for the purpose described, and a spring-controlled dog adapted to bear against the shoulders and to hold the lid in a lowered or raised position respectively with relation to the pen-point.

7. A cylindrical ferrule provided with forwardly-extending cheeks, rounded and reinforced substantially as shown and described, an ink-retaining lid pivotally mounted between the cheeks, and a spring-controlled dog adapted to bear against the lid and to hold it in a lowered or raised position, respectively with relation to the pen-point.

8. A cylindrical ferrule provided with forwardly-extending cheeks rounded and reinforced substantially as described, an ink-retaining lid pivotally mounted between the cheeks, provided with bearing-shoulders, a dog adapted to bear against the shoulders, said dog having a stem and a coiled spring surrounding the stem on the dog and inclosed within the cylindrical ferrule.

9. The combination of an outer penholder-ferrule and an inner cylindrical ferrule provided with forwardly-extending reinforced cheeks, an ink-retaining lid pivotally mounted between the cheeks provided with bearing-shoulders at its inner end, a spring-controlled dog located within the inner ferrule and adapted to exert holding pressure upon the shoulders of the lid and means for connecting the parts together, substantially as set forth.

10. A penholder provided with means for holding the pen, a pivoted lid provided with bearing-shoulders adapted to be raised from and to be closed upon and to form with the pen an ink-holding cavity, provided with grooves on its under surface leading to its tip, and a spring-controlled dog adapted to bear against the shoulders and to hold the lid in a lowered or raised position.

708,222. **INCANDESCENT GAS-BURNER.** THOMAS GORDON, Philadelphia, Pa. Filed July 26, 1901. Serial No. 69,758. (No model.)

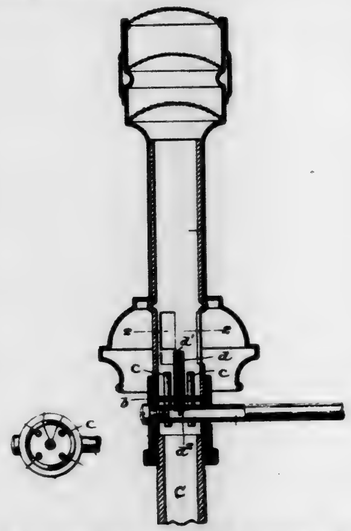
Claim.—1. In a gas-burner, the combination with an induction and mixing chamber, and a gas-supply pipe having communication therewith, of an air-supply pipe, and means at the bottom of said chamber providing an elongated annular duct connecting the chamber with said air-supply pipe, the outlet or discharge portion of said duct being open and unobstructed.

2. In a gas-burner, the combination with the induction and mixing chamber and the gas-supply pipe having communication therewith, of the air-supply pipe, a tube leading therefrom to the said chamber, and a core in said tube, affording in the latter an annular duct having an open unobstructed outlet.

3. In a gas-burner, the combination with the induction and mixing chamber and the gas-supply pipe having communication therewith, of the air-supply pipe, a tube leading therefrom to the said chamber, and a loosely-mounted stem or pin in said tube.

4. In a gas-burner, the combination with the induction and mixing chamber, and the air-supply pipe having central communication with said chamber adjacent the bottom of the latter, of the gas-supply pipe, and

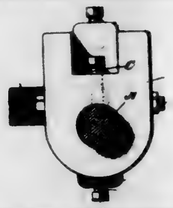
the elongated gas-ingress tubes disposed in the bottom of the said chamber independently and laterally of the point of communication between the air-supply pipe and said chamber.



5. In a gas-burner, the combination with the induction and mixing chamber, of the gas-supply pipe, the elongated gas-ingress ducts in the bottom of said chamber, the air-supply pipe, and a centrally-disposed annular duct leading therefrom to the said chamber, said duct having an open unobstructed outlet.

6. In a gas-burner, the combination with an induction and mixing chamber, a gas-supply pipe, and an air-supply pipe, of elongated gas-ingress ducts in the bottom of said chamber, an elongated air-duct leading from the air-supply pipe to said chamber, and an axially-disposed stem or pin in said air-duct.

708,223. ADJUSTABLE ECCENTRIC. HENRY GRAFF, Philadelphia, Pa. Filed Oct. 3, 1901. Serial No. 77,401. (No model.)

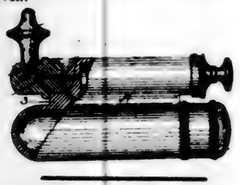


Claim.—In an apparatus of the character described, two guide-blocks secured upon the end of a power-shaft, guideways formed in said guide-blocks, slides adapted to slide within said guideways, a wrist-pin connected to each of said slides and extending between the same, slots formed through the slides, bolts secured in the guide-blocks upon each side of the slides and extending through the slot within said slide, and screws threaded through each end of the slides and adapted to bear against the bolts upon opposite sides, substantially as described and for the purpose specified.

708,224. SYRINGE. FRANK C. COUDLAGH and WILLIAM R. LUDEWIG, Pittsburg, Pa. Filed Oct. 14, 1901. Serial No. 79,134. (No model.)

Claim.—1. In a device of the character herein described, the combination of a syringe and a reservoir, one end of the syringe terminating in a socket having a centrally-disposed channel communicating with the interior of the syringe, and a channel near the edge thereof communicating with the reservoir, and a nozzle having an orifice in alinement with the central channel in the bottom of the socket and adapted when tightly seated in the socket, to close the channel between the socket and the reservoir.

2. In a device of the character herein described, the combination of a syringe, a reservoir and tablet-receptacle, one end of the syringe terminating in a socket adapted to communicate with the reservoir and the liquid-chamber of the syringe, in combination with a plug seated in said socket and adapted to control the means of communication between the socket and reservoir.



708,225. ELASTIC TIRE AND PROCESS OF MANUFACTURING SAME. FRANK E. HALL, Quincy, Mass. Filed Feb. 23, 1900. Serial No. 6,137. (No model.)

Claim.—1. The herein-described process which consists, first, in semivulcanizing the tire in a mold to give it its cross-section shape, second, in coiling said tire with a circumference less than its circumference when applied to the wheel to expand the outer periphery, and third, in fully vulcanizing said tire in its coiled position so that when applied to the wheel the outer periphery will compress.

2. The herein-described process, which consists, first, in semivulcanizing the tire in a straight mold to give it its cross-section shape, second, in coiling said tire with a circumference less than its circumference when applied to the wheel to expand the outer periphery, and third, in fully vulcanizing said tire in its coiled position so that when applied to the wheel the outer periphery will compress.

3. The herein-described process which consists, first, in semivulcanizing the tire in a mold to give it its cross-section shape with one or more continuous passages, second, in coiling said tire with a circumference less than its circumference when applied to the wheel to expand the outer periphery, and third, in fully vulcanizing said tire in its coiled position so that when applied to the wheel the outer periphery will compress.

4. The herein-described process which consists, first, in semivulcanizing the tire in a mold to give it its cross-section shape with one or more continuous passages and with a reinforced base, second, in coiling said tire with a circumference less than its circumference when applied to the wheel to expand the outer periphery, and third, in fully vulcanizing said tire in its coiled position so that when applied to the wheel the outer periphery will compress.

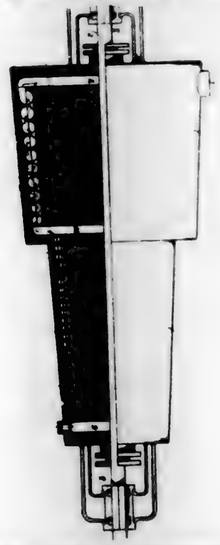
5. As an article of manufacture, an elastic tire provided with one or more continuous longitudinal passages and having a normal circumference less than its circumference when applied to the wheel and having an outer periphery longer than its inner periphery and provided with reinforcing material vulcanized in said passages and with yielding reinforcing material vulcanized to its base.

708,226. ADJUSTABLE SHADE-BRACKET. AUGUST HANSON, New Haven, Conn. Filed Jan. 20, 1902. Serial No. 90,500. (No model.)

Claim.—1. The combination with the recessed and slotted face-plate, of the shade-bracket having an apertured reduced end, a block arranged in the recess of the face-plate and having an extension fitting into the aperture of the reduced end of the shade-bracket, and means for connecting the bracket-plate and block as set forth.

2. The combination with the recessed and slotted face-plate of the shade-bracket having an apertured reduced end and a perforated angular flange and block arranged in the recess of the face-plate, and having an extension fitting into the apertured end of the shade-bracket, and a bolt passing through the perforated flange and entering the said block as and for the purpose described.

708,227. STEAM-TURBINE. ROBERT B. HEWSON, San Francisco, Cal. Filed Mar. 7, 1902. Serial No. 97,038. (No model.)



Claim.—1. The combination in a steam-turbine of a revoluble conical part having open buckets in annular successive series around its periphery, an inclosing casing within which the movable part fits and is revoluble, corresponding open buckets formed in said casing and in planes intermediate to the planes of the buckets of the cone, means for admitting an elastic medium under pressure to the smaller end of the cone, and transmitting it alternately through the buckets of the cone and those of the casing to the larger end and exhaust.

2. The combination in a steam-turbine of an approximately cylindrical or conical part, a casing within which it is journaled and revoluble, said revoluble part having open buckets arranged in annular series around its periphery and from end to end with intermediate ring or barrier surfaces, correspondingly-shaped open buckets reversed in position within the interior of the casing, intermediate between the buckets of the movable part, and also having ring or barrier stops interposed between each series of buckets.

3. The combination in a steam-turbine of a plurality of approximately cylindrical or conical parts, with offsets at the junction of each smaller and larger section, a correspondingly-shaped casing within which the first portion is turnable, open buckets formed in series around the sections and of gradually-increasing size, each series being separated from the adjacent series by rings or barriers, corresponding open buckets formed in the interior of the casing and having a reversed position from those of the revoluble part, and lying intermediate between each series of said part whereby the medium under pressure is caused to pass from end to end of the apparatus in alternate reverse curves through the stationary and movable buckets and is expanded at each successive passage.

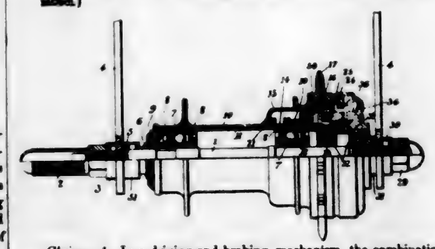
4. The combination in a steam-turbine of a part consisting of a series of frustums of cones, each larger in diameter than the preceding ones, a casing having the same shape within which said cones are journaled and revoluble, concave-convex buckets formed in series around the cones, and of successively-increasing size from the smaller to the larger end, correspondingly-shaped buckets reversed in position within the interior of the casing, each series forming a connection between the two adjacent series of the cone, and intermediate annular separating-surfaces between each series of buckets of the cone and of the casing.

5. The combination in a steam-turbine of a series of cones, each of larger diameter than the preceding and having a common axis, a casing of same shape within which the cones are journaled and turnable, buckets formed in successive series around the cone with intermediate separating barrier-surfaces, corresponding buckets reversely formed within the casing and connecting with each adjacent series of buckets of the cone, an annular chamber with which the smaller end of the first cone connects into which the medium under pressure is admitted, a second annular chamber intermediate between the first and second cone into which the medium from the first cone is exhausted and from which it is delivered to the buckets of the second cone and an exhaust-chamber into which the medium is delivered from the second cone.

6. A steam-turbine comprising a plurality of approximately cylindrical or conical parts and correspondingly-shaped casings within which they are revoluble, buckets formed in series around the revoluble part from one end to the other, said buckets being made semicircular at the deepest end and having curved diminishing lobes forming the rear ends, said lobes having a curvature corresponding with the semicircular end of the next succeeding bucket, annular barrier-surfaces interposed between each adjacent series of buckets, correspondingly-shaped buckets formed in the interior of the casing, and in reverse position to those of the revoluble part, said buckets alternating with those of the revoluble part and forming a connection between each two adjacent series thereof, the casing-buckets having corresponding barrier-surfaces between them whereby the medium under pressure is caused to act directly and with impulsive and reactionary effect as it passes through the buckets from one end to the other.

7. A steam-turbine consisting of an approximately cylindrical or conical part and a correspondingly-shaped casing within which the first portion is journaled to fit and revolve, both of said parts having reversely-disposed open buckets (interior to) the fitted contiguous surfaces with intermediate barriers, and means admitting an elastic medium under pressure to pass alternately through said buckets.

708,228. BACK-PEDALING BRAKE. ERNST G. HOFFMANN, Chelmsford, England. Filed May 10, 1900. Serial No. 16,147. (No model.)



Claim.—1. In a driving and braking mechanism, the combination with a hub having a flange on same, and a spindle on which the hub can rotate, of a free driving member, means carried by the hub for obtaining a lateral motion of such member to bring it into contact with the flange on the hub for driving purposes and means carried by the spindle for obtaining a similar lateral motion of such member to bring it also into contact with the flange on the hub for braking purposes.

2. In a driving and braking mechanism, a hub, a spindle on which same can rotate, a free driving member at the extremity of said hub having interior cam-surfaces, a projection carried by the hub having a conical face, a cage inside such free driving member and movable over such conical face, a flange on the hub coöperating with the free driving member and movable parts in such cage coöperating with the conical face and the cam-surfaces of the free driving member whereby a forward movement imparted to the free driving member will produce a movement of the cage and impart a lateral movement to said free driving member to bring it into frictional contact with the flange on the hub.

3. In a driving and braking mechanism, a hub, a spindle on which same can rotate, an abutment carried by the spindle having cam-surfaces movable parts on such cam-surfaces, a free driving member between the hub and the abutment having interior cam-surfaces, a flange on the hub coöperating with the free driving member, a projection carried by the hub having a conical face, a cage inside such free driving member and movable over such conical face, movable parts in such cage, coöperating with the conical face and the cam-surfaces of the free driving member whereby a forward movement imparted to the free driving member will produce a spiral movement of the cage and impart a lateral movement to said free driving member to bring it into frictional contact with the flange on the hub for driving while a backward movement of the free driving member causes the movable parts on the abutment to rise up the cam-

surfaces and also force the free driving member frictionally against the flange on the hub for braking.

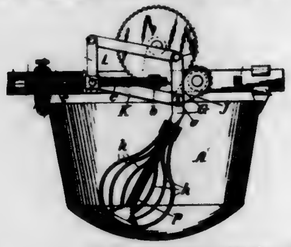
4. In a driving and braking mechanism, the combination with the hub of a free driving member, a series of cam-surfaces on the interior of same, a conical face carried by the hub, and rolling parts between the conical face and the cam-surfaces whereby a forward movement given to the free driving member will give the rolling parts a tendency to travel up the conical face the movement of the free driving member also causing them to roll on the cam-surfaces of such member the combined movement producing a spiral movement of the free driving member in the direction of the hub with which it then engages.

5. In a driving and braking mechanism, a hub, a flange on same, a spindle on which same can rotate, a disk-shaped abutment on the spindle having cam-surfaces and rolling parts thereon, a free driving member between the hub and the abutment having a series of cam-surfaces in the interior of same, a projection carried by the hub having a conical face, and rolling parts between such conical face and the cam-surfaces of the free driving member whereby a forward movement imparted to the free driving member will also act to produce in it a spiral movement to bring it into frictional contact with the flange on the hub for driving, a backward movement of the free driving member causing the rolling parts on the abutment to rise up the cam-surfaces thereof and also force the free driving member frictionally against the flange on the hub for braking.

6. In a driving and braking mechanism, and in combination, a hub having an expanded extension 15, a projection 14, a conical ring carried thereby, a spindle on which such hub can rotate, a disk-shaped abutment on the spindle having a series of cam-surfaces thereon, a rolling part for each cam-surface, a free driving member between the abutment and the hub having a series of cam-surfaces in the interior of same, balls between the cam-surfaces of such free member and the conical ring, a ball-bearing for such free member, a conical sleeve 19 adapted to slide on the projection 14 and forming part of such bearing, and a spring for pressing such sleeve 19 forwardly so that adjustment of the bearings is constantly maintained.

7. In a driving and braking mechanism, the combination with a hub, a flange on same, a spindle on which said hub can rotate, an abutment on the spindle having cam-surfaces and rolling parts thereon and a free driving member between the hub and its abutment having cam-surfaces inside same, of a projection 14 on said hub, having a conical surface 13, a loose cage between such surface and the free driving member, balls carried by such cage adapted to contact with the conical surface 13 and the cam-surfaces of the free driving member and a coil-spring engaging with the free member and with the cage whereby the latter will be kept in a position so that the balls will be forced into the narrowest point between the cams on the free driving member and the conical surface so that the free driving member is always ready for forward driving.

708,229. AERATING-AGITATOR. BENJAMIN D. HOOPER, Jamaica, N. Y. Filed Oct. 8, 1901. Serial No. 78,018. (No model.)



Claim.—1. In an aerating-agitator, the combination with the agitating member thereof, and means for bodily gyrating the same in a vertical, or nearly so, plane, of means for forcing air, or any other gas, into the mass to be agitated, during the motion of the agitated member, substantially as, and for the purposes, described.

2. In an aerating-agitator, the combination with a supporting-frame, of a wheel mounted thereon, a framework of arms pivoted together and forming a parallelogram, means for imparting motion from said wheel to the parallelogram, whereby the angles of said arms with respect to each other are altered, a pump, means for imparting motion from said framework to the pump, an agitating member carried by said framework, and means for supplying pressure from said pump to said agitating member substantially as described.

3. In an aerating-agitator the combination with the air-pump cylinder of a hollow piston and piston-rod, a hollow connecting-rod, a pin pivotally connecting the said rods provided with two annular grooves and a connecting-groove, a crank, a crank-pin provided with two annular grooves and a connecting-groove, a hollow agitator-arm, a hollow air-nozzle, and means for imparting motion to the said crank, substantially as described.

4. In an aerating-agitator, the combination with any suitable support, of a framework forming a parallelogram and having the contacting ends of all its arms pivoted together, said framework being mounted upon said support, a pump connected with said framework, means for imparting motion to said framework, whereby the angles of said arms are altered with respect to each other for operating said pump, an agitator member carried by one of the arms of said framework, and means for communicating pressure from said pump to said agitator member, substantially as described.

5. In a mechanism of the class described, the combination with a suitable support, of a crank pivotally mounted thereon, means for rotating said crank, an agitating member pivoted to said crank, means for guiding said member in its movement while following the crank, whereby said agitating member will be directed in a bodily, vertically rotatory or gyrating movement, and means for supplying atmosphere to the lower end of said member during operation thereof, substantially as described.

6. An aerating-agitator, comprising a suitable supporting-frame, a pump mounted thereon, a pinion carried by said frame, a crank operated thereby, an agitator member pivotally secured to said crank, means connecting said pump with said crank, means for rotating said pinion, and means of communication from said pump with said agitator member, whereby rotation of said pinion will gyrate said agitator member and supply gas under pressure thereto, substantially as described

---

708,230. BOOK FOR HOLDING AND FILING SALES-SLIPS, &c. JOHN F. HUBER, Rochester, N. Y., assignor to Lewis T. Huber, Lockport, N. Y. Filed June 24, 1901. Serial No. 65,765. (No model.)

Claim.—1. The combination with a plurality of leaves hinged together at one edge to form a book, of a plurality of flat spring-clips secured on each leaf inside of the free edges thereof and each adapted to hold bills, slips or cards in contact with the latter.

2. The combination of a plurality of leaves, hinged together at one edge to form a book, each leaf having a plurality of holding-clips on each side thereof, the clips on opposite sides of the same leaf being composed of a single piece of spring material extending through the leaf and having portions pressing toward the sides of the leaf.

3. The combination with the apertured leaf or support of sheet material, of a duplex clip for holding slips on both sides of the sheet embodying a piece of spring material passing through the aperture in the sheet and having its free end portions on opposite sides thereof and movable toward and from the sheet.

4. The combination with the leaf or support of sheet material, of the clips thereon composed of the single piece of spring material extending through the support and having the annular spring-arms on opposite sides thereof.

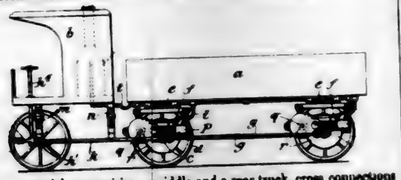
5. An article of manufacture consisting of a book for holding sales-slips, &c., embodying the covers, the rods pivotally connecting the inner edges of the covers, the leaves arranged between the covers having flexible hinge members thereon engaging the rods, and holding-clips on the leaves consisting of the spring-wire extending through the leaves and having a coil on each side thereof.

6. In a book for holding sales-slips, &c., the combination with the covers having the binding-strips at the edges, and the continuous rod extending longitudinally in the strips and between the ends of the covers, of the rods having the eyes arranged intermediate said ends and engaging the binding-strip, and the leaves having the flexible ears thereon engaging the rods and arranged between the covers.

708,231. VEHICLE. CHARLES W. HUFF, West New Brighton, N. Y. Filed June 14, 1902. Serial No. 111,627. (No model.)

Claim.—1. A vehicle comprising a middle and a rear truck, cross connections between said trucks, a forward steering-truck, and a rigid frame or reach connecting said steering-truck with the middle truck, substantially as described.

2. A vehicle comprising a middle and a rear truck, cross connections between said trucks, a forward steering truck, a rigid frame or reach connecting said steering-truck with the middle truck, and a motor applied to the wheels of one of said trucks, substantially as described.



3. A vehicle comprising a middle and a rear truck, cross connections between said trucks, a forward steering-truck, a rigid frame or reach connecting said steering-truck with the middle truck, and a motor mounted on the axle of one of said trucks and applied to the wheels of said truck, substantially as described.

4. A vehicle comprising a middle and a rear truck, cross connections between said trucks, a body mounted on said trucks, a forward steering-truck, a rigid frame or reach connecting said steering-truck with the middle truck, and an independent body mounted on the steering-truck and reach, substantially as described.

5. A vehicle comprising a middle and a rear truck, cross connections between said trucks, a body mounted on said trucks, a forward steering-truck, a rigid frame or reach connecting said steering-truck with the middle truck, an independent body mounted on the steering-truck and reach, a motor applied to the wheels of the middle or rear truck, and a source of power mounted on said independent body, substantially as described.

708,232. SPROCKET-WHEEL. DANIEL C. JACKLING, Republic, Wash. Filed Aug. 3, 1901. Serial No. 70,642. (No model.)

Claim.—In a sprocket-wheel of the class described, the combination of a main disk having a plurality of radial grooves in its inner side and a projecting hub, a second disk rotatably mounted upon such hub adjacent to the main disk and provided with a plurality of tangential cam-grooves upon its inner side extending to the periphery of such disk, a sprocket-tooth slidably mounted in each of the radial grooves of the main disk and having a projecting shoulder on the inner end thereof extending into a tangential groove of the second disk, each of such teeth being provided with projecting shoulders near its outer end for forming a chain-supporting base, and bolt-and-nut mechanism for holding the disks and thereby the sprocket-teeth in position, substantially as described

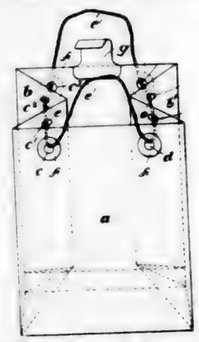
---

708,233. HOOP-LUG. PETER C. JUBA, Jr., San Francisco, Cal. Filed Mar. 24, 1902. Serial No. 99,834. (No model.)

Claim.—In a hoop-lug, a block having a longitudinal slot for the reception of the hoop-band, said slot having its upper wall concaved and approaching the lower wall abruptly at either end of the block, a longitudinal central opening for the bolt, partitions 11 on either side of the bolt, said partitions dependent from the upper wall of the band-slot and balls having a limited reciprocal movement in the space formed between said partitions and the side walls of the slot, said ball-spaces extending substantially the entire length of the block.

708,234. PAPER BAG. HUGH LAIRD, Turriston, Scotland. Filed Dec. 18, 1901. Serial No. 86,371. (No model.)

Claim.—1. A paper bag made with bellows-like sides and folded bottom, said bag being provided with two series of holes near the top, the holes, four in each series, passing through the front and back of the bag and through the folded side portions thereof, the exterior holes being protected by applied washers as explained, and a draw-string serving to close the bag when lifted and to operate as a handle, the parts being arranged and combined substantially as shown and described.



2. The herein-described paper bag, the same being made with bellows-like sides and folded bottom, provided with two series of holes near the top, the holes, four in each series, passing through the front and back of the bag and through the folded side portions thereof, the exterior holes being protected by applied washers as explained, a draw-string serving to close the bag when lifted and to operate as a handle, and a gummed tongue on the top of one side, substantially as herein set forth.

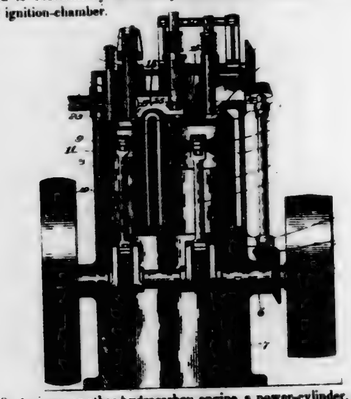
708,235. GUN-CARRIAGE. OTTO LAUBER, Essen-Altendorf, Germany, assignor to Fried. Krupp, Essen, Germany. Filed Sept. 21, 1901. Serial No. 76,013. (No model.)

Claim.—In a recoil apparatus for field-gun carriages, the combination with a brake-spur, a thrust-bolt engaging at one end with said spur and having a solid angular shank and a compression-box comprising two bearings or brasses provided with angular grooves, one of said brasses being movable, said grooves embracing the angular faces of the thrust-bolt, whereby, without intervention of other mediums, pressure on one of said brasses produces friction between said grooves and the angular faces of said shank.

708,236. GAS-ENGINE. WILLIAM A. LEONARD, Wareham, Mass. Filed July 19, 1901. Serial No. 68,870. (No model.)

Claim.—1. In a gas-engine, a power cylinder, a pump-cylinder, a single cylinder-head for both said cylinders, an inlet-port leading through the cylinder-head and opening into the end of the pump-cylinder, an exhaust-port for the power-cylinder also extending through the cylinder-

head, an ignition-chamber in said cylinder-head and having communication with each cylinder, a puppet-valve controlling the inlet-port to the pump-cylinder, a second puppet-valve controlling the exhaust from the power-cylinder, a third puppet-valve controlling the communication between the pump-cylinder and the ignition-chamber, and a fourth puppet-valve controlling the inlet between the ignition-chamber and power-cylinder, all of said valves being carried by and operating in the cylinder-head and each of said valves being independent from the others and when closed having its face flush with and constituting part of the end of the cylinder, positive valve-actuating mechanism for the valve controlling the inlet to the power-cylinder and that controlling the exhaust therefrom, said mechanism operating to close the inlet-valve at the finish of the outward stroke of the power-piston, and also operating to close the valve in the exhaust-port before the power-piston reaches the end of its inward stroke, whereby the gases remaining in the power-cylinder are compressed to substantially the same pressure as the charge of air and gas in the ignition-chamber.



2. In a gas or other hydrocarbon engine, a power-cylinder, a piston therein, an ignition-chamber separate from, but having a valved connection with the cylinder, means to admit a charge of gas to said ignition-chamber and means to explode the same at each outward stroke of the piston, and means to admit a scavenging charge of fresh air directly to said ignition-chamber during the latter part of each outward stroke.

3. In a gas or other hydrocarbon engine, a power-cylinder, a piston therein, an ignition-chamber connected to said cylinder but separate therefrom, a valve controlling the communication between the ignition-chamber and cylinder, means to admit a charge of gas to said chamber at each inward stroke of the engine, igniting devices, and means to admit a scavenging charge of fresh air directly to said ignition-chamber during the latter part of each outward stroke.

4. In a gas-engine, a power-cylinder, an ignition-chamber separate from said cylinder and connected thereto, an inlet-valve between said cylinder and chamber, an automatic scavenging-valve to admit fresh air directly to said chamber, the relation between the parts being such that during the latter part of each outward stroke a partial vacuum is created in the power-cylinder and fresh air is drawn directly into the ignition-chamber through the scavenging-valve.

5. In a two-cycle gas-engine, a power-cylinder, a piston therein, an ignition-chamber connected to the cylinder, means to admit a charge of gas to said chamber, means to ignite the same slightly before, or during, the early part of each outward stroke of the piston, combined with a spring-controlled scavenging-valve leading to said chamber and adapted to admit fresh air directly into the latter, the piston operating at the end of each outward stroke to create a partial vacuum in the cylinder and draw fresh air directly into the ignition-chamber through the scavenging-valve.

6. In a two-cycle gas-engine, a power-cylinder, a piston therein, a pump-cylinder and its coöperating piston, a chamber between said cylinders, a valve between each cylinder and the chamber, and a scavenging-valve to admit fresh air to said chamber, the parts being so disposed that the pump-piston operates to force a charge of compressed gas into the chamber where it is ignited, the ignited gas operating on the power-piston to give an impulse to the same, and the said piston operating to create a partial vacuum in the cylinder and draw a scavenging charge of fresh air into the chamber through the scavenging-valve.

7. In a gas or other engine, a power-cylinder, a piston therein, a pump-cylinder and piston, a chamber between said cylinders, an automatic valve between the chamber and pump-cylinder, a positively-operated inlet-valve between the chamber and the power-cylinder, and an automatic scavenging-valve to admit fresh air directly to said chamber, the parts being so disposed that on each inward stroke of the pump-piston a charge of gas is compressed in the chamber, and as the power-piston reaches the end of its inward stroke the inlet-valve is opened and the charge ignited, the power-piston during the latter part of its stroke operating to create a partial vacuum in the power-cylinder, and draw a scavenging charge of fresh air directly into the chamber.

8. In a gas-engine, a power-cylinder, a piston therein, a pump-cylinder and its piston, a chamber between said cylinders, an automatic valve between the chamber and the pump cylinder, an inlet-valve between the chamber and the power-cylinder, and an exhaust-valve, said valves being independent from each other, valve-actuating mechanism operating to close the exhaust-valve before the power piston reaches the end of its inward stroke, whereby the said piston is cushioned, and to open the inlet-valve and admit the compressed gases in the chamber into the power-cylinder, said inlet-valve remaining open until the piston reaches the end of its outward stroke, an automatic valve to admit fresh air directly to the chamber, the piston during the latter part of its stroke creating a partial vacuum in the power-cylinder and drawing a scavenging charge of air into the chamber, said scavenging charge remaining in the chamber during the exhaust.

9. In a gas-engine, a power-cylinder, a piston therein, an ignition-chamber separate from said cylinder but connected thereto, an inlet-valve between the chamber and said cylinder, valve-operating mechanism, said cylinder having an exhaust-valve, means to compress a charge of explosive gas in said chamber and ignite the same, said explosive gas impelling the piston forward, and means whereby the piston during the latter part of its outward stroke draws a scavenging charge of fresh air into said chamber, said inlet-valve being closed as the piston begins its inward or return stroke, whereby the burned gases are expelled through the exhaust-valve and the scavenging charge of fresh air remains in the cylinder.

10. In a two-cycle gas-engine, a power-cylinder, a piston therein, an ignition-chamber connected to the cylinder, an inlet-valve between the chamber and cylinder, valve-operating mechanism, an exhaust-valve leading from the said cylinder, means to admit a charge of gas to said chamber, means to ignite the same slightly before or during the early part of each outward stroke of the piston, combined with a spring-controlled scavenging-valve leading to said chamber and operating to admit fresh air directly into the latter, the piston operating at the latter part of its outward stroke to create a partial vacuum in the cylinder and draw fresh air directly into the ignition-chamber through the scavenging-valve, and said inlet-valve closing as the piston begins its return stroke, whereby the burned gases are expelled through the exhaust-valve while a scavenging charge of air remains in the said chamber.

11. In a two-cycle gas-engine, a power-cylinder, a piston therein, a pump-cylinder and its coöperating piston, a chamber between said cylinders, a valve between the pump-cylinder and the chamber, and an inlet-valve between the power-cylinder and the chamber, an exhaust-valve leading from the said power-cylinder, a scavenging-valve to admit fresh air directly to said chamber, and valve-operating mechanism, the parts being so disposed that the pump-piston operates to force a charge of compressed gas into the chamber where it is ignited, the ignited gas operating on the power-piston to give an impulse to the same, the said power-piston operating during the latter portion of its outward stroke to create a partial vacuum in the said cylinder and draw a scavenging charge of fresh air into the chamber through the scavenging-valve, and the inlet-valve closes when the power-piston has reached the limit of its outward stroke, whereby the burned gases are expelled through the exhaust-valve, while the scavenging charge of fresh air remains in the said chamber.

12. In a gas or other engine, a power-cylinder, a piston therein, a pump-cylinder and piston, a chamber between said cylinders, an automatic valve between the chamber and pump-cylinder, a positively-operated inlet-valve between the chamber and the power-cylinder, an exhaust-valve for the power-cylinder, valve-operating mechanism for the inlet and exhaust valves, and an automatic scavenging-valve to admit fresh air directly to said chamber, the parts being so disposed that as the power-piston reaches the end of its inward stroke the inlet-valve is opened and the charge ignited, and as the power-piston reaches the end of its outward stroke the said inlet-valve is closed, the power-piston during the latter part of its outward stroke operating to create a partial vacuum in the power-cylinder and draw a scavenging charge of fresh air directly into the chamber, and during its return stroke operating to expel the burned gases from the cylinder, the scavenging charge of air remaining in the chamber.

708,237. PYROTECHNIC DEVICE. THOMAS LLOYD, New York, N. Y. Filed May 31, 1902. Serial No. 109,714. (No model.)

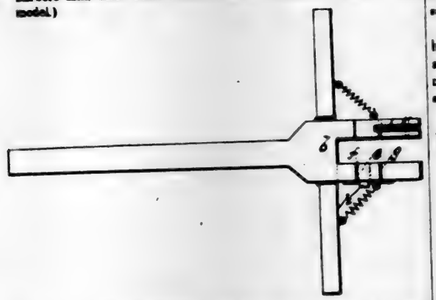
Claim.—1. A pyrotechnic device comprising a body having a base and an upright portion; said upright portion being made to resemble a volcano, and being provided with a receptacle containing a suitable pyrotechnic compound, and one or more strips of combustible material made to resemble a building or buildings, arranged on and rising from the base of the body.

2. A pyrotechnic device comprising a body having a base, and an upright portion flexibly joined to and adapted to fold upon the base; said upright portion being made to resemble a volcano, and being provided with a receptacle containing a suitable pyrotechnic compound, and one or more strips of combustible material made to resemble a building or buildings; said strip or strips being flexibly joined to and rising from the base of the body, and being adapted, when the upright portion of the body is folded upon the base, to fold between said upright portion and base.

3. The herein-described pyrotechnic device comprising the body formed of a single piece of pasteboard, creased longitudinally at *c*, and having a base and an upright portion separated by said crease; the said upright portion being made to resemble a volcano, a receptacle arranged on the rear side of the upright portion of the body and containing a suitable pyrotechnic compound, and strips flexibly joined to and rising from the base of the body; the said strips being a paper chemically treated to render them highly combustible, and being made to resemble the buildings of a city or village.

4. The herein-described pyrotechnic device comprising the body formed of a single piece of pasteboard, creased longitudinally at *c*, and having a base and an upright portion separated by said crease; the said upright portion being made to resemble a volcano, a receptacle arranged in the rear side of the upright portion of the body and containing a suitable pyrotechnic compound, a stay of pasteboard attached to the back of the upright portion of the body and having the extended end *e*, and strips flexibly joined to and rising from the base of the body; the said strips being of paper chemically treated to render them highly combustible and being made to resemble the buildings of a city or village.

708,238. DEVICE FOR HOLDING DOORS. LEVI H. LUCABAUGH, Barbers Mill, Ind. Filed June 10, 1902. Serial No. 111,021. (No model.)



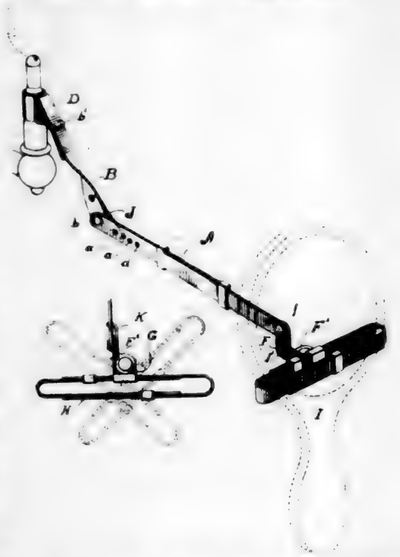
Claim.—1. The combination with the forked base-bar and grooved standard of the pressure-bar having the guide-pins, the inclined slots to receive said pins and the handle for operating said bar, substantially as described.

2. In combination with the grooved and slotted standard, of the pressure-bar and handle therefor, the slotted floor-hook pivoted in the kerf in the forked end of the base, the hinged angular side wings or braces and hooks for holding said wings in position while the device is in operation, all substantially as described.

708,239. FOLDING MIRROR-SUPPORT. BERNARD C. LYON, New London, Conn. Filed May 4, 1901. Serial No. 58,702. (No model.)

Claim.—1. A mirror-holder comprising a main arm, a link attached to one end of said arm, a tubular member attached to said link, said tubular member being adapted to slip on over the tip of a gas-burner, a blade projecting from said tubular member downward at an angle thereto, and means attached to the other end of said main arm for holding a mirror at various angles.

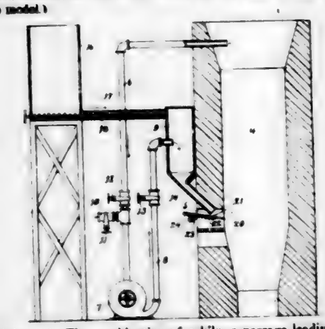
2. A mirror-holder comprising a series of hinged arms vertically adjustable, means consisting of hooks for holding said hinged arms at operative positions, a tubular device attached at one end of one of said arms adapted to be removably secured to a tubular support, and a frame attached to one of said arms for holding a mirror, said frame being composed of extensible loops with means for adjusting the same.



3. A mirror-holder comprising a main arm A, a link B hinged to said arm, a clip D hinged to said link, a tubular support E adapted to be secured to said clip, said clip and tubular support being adapted to be attached to a window and to a gas-burner, respectively, and means attached to said arm A for holding a mirror at various angles, said means comprising an extensible frame hinged to said main arm and adjustable with respect thereto.

4. A mirror-holder comprising arm A, link B hinged thereto, clip D hinged to said link B, a blade D' secured to said clip D and projecting at an angle therefrom, and means for attaching said clip to a supporting member, and means for holding a mirror, said means being hinged to said arm A.

708,240. APPARATUS FOR BURNING LIME. GARWIN A. MACK, Menominee Falls, Wis. Filed Feb. 28, 1902. Serial No. 96,074. (No model.)



Claim.—1. The combination of a kiln, a passage leading from the kiln back to the fire, means within the passage for drawing the hot air and gases from the kiln into said passage and back to the fire, a mixing-chamber to which the passage leads, said mixing-chamber being in communication with the fire-chamber of the kiln, a valve in the passage between the mixing-chamber and the drawing or suction means, a valve in said passage in advance of said drawing or suction means and communicating with the in advance of the drawing or suction means and communicating with the

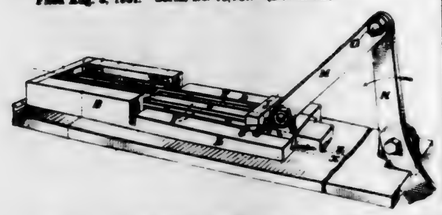
passage, and means for feeding a fuel to the mixing-chamber, said fuel and the hot air and gases being thereby mixed and commingled in the mixing-chamber, before being finally conducted into the fire.

2. The combination of a kiln, a plate in the fire-chamber thereof, means for adjusting said plate inwardly and outwardly, and means for discharging a fuel onto the plate to thereby give said fuel an initial heating.

3. The combination of a kiln, a plate in the fire-chamber thereof, a passage leading from the kiln at a point above the fire-chamber and extending back to said fire-chamber, means for drawing hot air and gases through said passage and back to the fire-chamber, and means for feeding fuel into said passage, and for discharging said fuel, and the hot air and gases mixed therewith onto the plate.

4. The combination of a kiln, a passage leading from the kiln back to the fire, means for drawing the hot air and gases from the kiln through said passage and back to the fire, a receptacle, a bin provided with an opening leading to the receptacle, a gate for said opening, means for agitating said gate, a conveyer adapted to convey the fuel discharged into the receptacle, and a conduit leading from the receptacle to the passage, the said conveyer adapted to conduct the fuel to the conduit, and the conduit to discharge said fuel into the passage, whereby the fuel is mixed with the hot air and gases prior to being discharged into the fire.

708,241. TILE-PRESS. WILLIAM P. MESSER, Newark, N. J. Filed Aug. 3, 1901. Serial No. 70,747. (No model.)



Claim.—1. In a tile-press, the combination, with a matrix provided with a removable side, of an inclined or beveled offset on the inner side of said matrix, and entirely surrounding the same in the angle between the base and sides of the matrix, substantially as described.

2. In a tile-press, the combination, with a stationary bed-plate and fixed matrix sides, provided interiorly with downwardly-beveled offsets, in the angle between the sides and bed-plate, of a laterally-removable matrix side, also provided with a downwardly-beveled offset on its inner face, adjacent to the bed-plate, substantially as described.

3. In a tile-press, the combination, with a stationary matrix-bed, of tapered and undercut flanges upon said bed, fixed matrix sides provided interiorly with downwardly-beveled offsets, and a laterally-removable matrix side, also provided with a downwardly-beveled offset on its inner face, substantially as described.

4. In a tile-press, the combination, with a stationary matrix-bed, of tapered and undercut flanges upon said bed, fixed matrix sides, provided interiorly with downwardly-beveled offsets, a laterally-removable matrix side, also provided with a downwardly-beveled offset on its inner face, and carrying fingers attached to said removable side and sliding between said undercut flanges upon said matrix-bed, substantially as described.

5. In a tile-press, the combination, with a stationary matrix-bed, of tapered and undercut flanges upon said bed, fixed matrix sides, provided interiorly with downwardly-beveled offsets, a laterally-removable matrix side, also provided with a downwardly-beveled offset on its inner face, and carrying fingers attached to said removable side and sliding between said undercut flanges upon said matrix-bed, and passing out through exteriorly-flaring holes in the rear side of said matrix, substantially as described.

6. In a tile-press, the combination, with a stationary matrix-bed, of tapered and undercut flanges upon said bed, fixed matrix sides, provided interiorly with downwardly-beveled offsets, a laterally-removable matrix side also provided with a downwardly-beveled offset on its inner face, and with outwardly-flaring holes to receive the ends of said undercut flanges, and carrying fingers attached to said removable side and sliding between said undercut flanges upon said matrix-bed, substantially as described.

7. In a tile-press, the combination, with a stationary matrix-bed, of tapered and undercut flanges upon said bed, fixed matrix sides provided interiorly with downwardly-beveled offsets, and a laterally-removable matrix side, also provided with a downwardly-beveled offset on its inner face, and with ends beveled to correspond with the said beveled offsets on the fixed sides of the matrix, substantially as described.

8. In a tile-press, the combination, with a stationary matrix-bed, of tapered and undercut flanges upon said bed, fixed matrix sides, provided interiorly with downwardly-beveled offsets, a laterally-removable matrix side, also provided with a downwardly-beveled offset on its inner face, and with outwardly-flaring holes to receive the ends of said undercut flanges, and carrying fingers attached to said removable side and sliding between said undercut flanges upon said matrix-bed, and with ends beveled to correspond with the said beveled offsets on the fixed sides of the matrix, substantially as described.

9. In a tile-press, the combination, in a matrix, having laterally-removable side and bottom members, of outwardly-flaring openings in the matrix sides for the relatively moving portions to pass through, substantially as described.

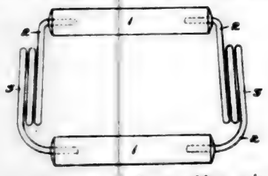
10. In a tile-press, the combination, in a matrix having laterally-removable side and bottom members, of outwardly-flaring openings in the matrix sides provided with closely-fitting inner edges, for the relatively moving inner portions to pass through, substantially as described.

11. In a tile-press, the combination, in a matrix, having laterally-removable side and bottom members of cutting edges upon the meeting portions of the relatively moving parts, substantially as described.

12. In a tile-press, the combination, with a matrix having relatively movable portions, of an opening through the base of the matrix beneath the relatively movable portions, substantially as described.

13. In a tile-press, the combination, with a matrix, having relatively movable portions, with cutting edges thereupon, of an opening through the base of said matrix beneath the point at which the cutting edges meet, substantially as described.

708,242. EXERCISING DEVICE. WILLIAM M. MOSELEY, Elgin, Ill. Filed Apr. 16, 1902. Serial No. 103,079. (No model.)



Claim.—1. An exercising device comprising a pair of handles and a pair of springs, each of which springs is coiled near its middle and fastened at its ends to the ends of the handles and with the coils of the springs each arranged at one side of the path of the handles.

2. The exercising device above described consisting of the handles 1, 1, the levers 2, 2, and the coil-spring 3 all organized as illustrated to cause movement of the handles 1, 1, toward each other so increase the effective length of the levers 2, 2, and to cause increasing resistance of coil-spring 3 to be balanced by the increasing leverage of levers 2, 2.

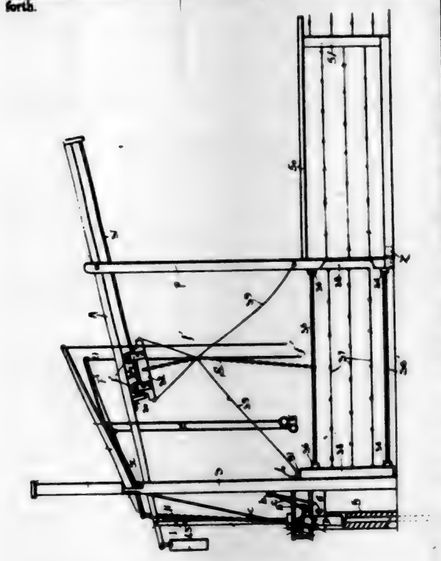
708,243. WINDING-KEY HEAD. THOMAS W. R. MCCABE, Winsted, Conn. Filed May 1, 1901. Serial No. 58,966. (No model.)

Claim.—The cylindrical ring-head reduced in diameter at one end one or more grooves extending the full length of the larger diameter, and mortises in said grooves, in combination with the loop having its ends entered in said mortises, all substantially as described.

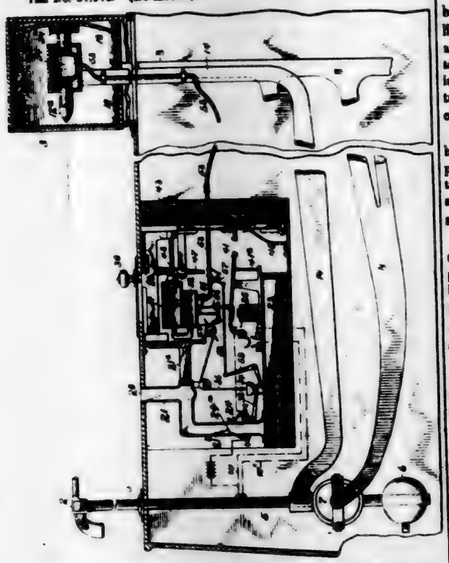
708,244. FARM-GATE. LEWIS K. MCCLELLAN, Cedar Rapids, Nebr. Filed Dec. 12, 1901. Serial No. 85,567. (No model.)

Claim.—1. The combination with a supporting-post, of a tilting lever secured to said supporting-post, a weight secured to one end of said lever, a shifting hanger working upon said lever, a fence-gate supported by said hanger, a hollow post, a housing secured to said post provided with suitable openings, a lifting-bar extending through said hollow post through said housing-openings and pivotally secured to the weighted end of said lever, a lifting-link adapted to engage said lifting-bar, masts positioned upon opposite sides adjacent said hollow posts, a lever pivotally secured to each mast, a detent within said housing adapted to engage said lifting-bar and operating-strands secured to said levers and to said detent, and strands connecting said lifting-link to each of said levers and arranged substantially as and for the purpose set forth.

2. The combination with a supporting-post, of a tilting lever secured to said supporting-post, a shifting hanger working upon said lever, a fence-gate supported by said hanger, a housing provided with suitable openings, a lifting-bar extending through said housing-openings and pivotally secured to one end of aforesaid lever, a lifting-link adapted to engage aforesaid lifting-bar, masts positioned adjacent said housing, a lever pivotally secured to each mast, a detent within said housing adapted to engage said lifting-bar, operating-strands secured to said last-mentioned levers and to said detent, and strands connecting said lifting-link to each of said last-mentioned levers all arranged substantially as and for the purpose set forth.



708,245. TARGET APPARATUS. JOHN L. MCCULLOUGH, Brooklyn, N. Y., assignor to Automatic Target Machine Company, a Corporation of New York. Filed Apr. 30, 1900. Renewed Dec. 31, 1901. Serial No. 87,978. (No model.)



Claim.—1. In a target apparatus, the combination with a penetrable target, a pistol or the like, and a universally-mounted support for the pistol, of an indicator back of the target and connected with the pistol-support, means for operating said indicator to cause it to protrude through the target, and means, controlled by the trigger of the pistol, for setting in operation the said indicator.

2. In a target apparatus, the combination with a penetrable target, a pistol or the like, and a universally-mounted support for the pistol, of an indicator back of the target and connected with the pistol-support, means for operating said indicator to cause it to protrude through the target, an indicator-lock, means for operating said lock and means controlled by the trigger of the pistol for setting in operation the said indicator and lock.

3. In a target apparatus, the combination with a penetrable target, a pistol or the like, and a universally-mounted support for the pistol, of an indicator back of the target and connected with the pistol-support, means for operating said indicator to cause it to protrude through the target, and electrical means, controlled by the trigger of the pistol, for setting in operation the said indicator.

4. In a target apparatus, the combination with a penetrable target, a pistol or the like, and a universally-mounted support for the pistol, of an indicator back of the target and connected with the pistol-support, means for operating said indicator to cause it to protrude through the target, an indicator-lock, means for operating said lock, and electrical means, controlled by the trigger of the pistol, for setting in operation the said indicator and lock.

5. In a target apparatus, the combination with a target, a pistol or the like, and a universally-mounted support for the pistol, of an electrically-operable indicator back of the target and connected with the pistol-support, an indicator-lock, means for actuating said indicator and lock and electrical means, controlled by the trigger of the pistol, for setting in operation simultaneously the said indicator and lock operating mechanisms.

6. In a target apparatus, the combination with a casing supporting the mechanism, a target, a target-box, a pistol mounted on a support on the casing, the said support, universally mounted in the casing, an indicator behind the target and carried by the pistol-support, and means for driving the indicator through the target, of electrical means, controlled by the trigger of the pistol, for setting in operation said indicator-actuating means.

7. In a target apparatus, the combination with a casing supporting the mechanism, a target, a target-box, a pistol mounted on a support on the casing, the said support, universally mounted in the casing, an indicator behind the target and carried by the pistol-support, means for driving the indicator through the target, an indicator-lock, means for operating said lock, and electrical means controlled by the trigger of the pistol for setting in operation said indicator and lock actuating means.

8. In a target apparatus, the combination with a target, a counterbalanced main frame pivotally suspended at the target, a pistol or the like on a support counterbalanced and jointed universally in said frame, and the said support, of an indicator at the target connected with the pistol-support and adapted to move about the target as the pistol is moved in aiming, means for operating said indicator, and electrical means, controlled by the trigger of the pistol for setting in operation the said indicator-actuating mechanism.

9. In a target apparatus, the combination with the casing, a target-box mounted thereon, a target, and a counterbalanced main frame 8, suspended at the target, of a counterweighted support or stem 5, for the pistol, mounted universally in the frame 8, the arm 14 carried by the stem 5 and extending up into the target-box, an indicator carried by said arm, and a pistol carried by the said stem 5.

10. In a target apparatus, the combination with a target, a pistol, an electric circuit adapted to be completed by actuating the trigger of the pistol, and a magnet 25 in the said circuit, of the sounding device, comprising a box 43, a hinged flap 44, and its spring 46, the armature-lever of the magnet 25, provided with a hook 50, the hook 49 on the flap 44, adapted to engage the hook 50, and means for drawing back said flap, substantially as set forth.

11. In a target apparatus, the combination with a target adapted to be penetrated without rupture, of a pointed indicator adapted to be protruded through said target, a simulated firearm, and means, controlled by the firing of said firearm, for operating said indicator.

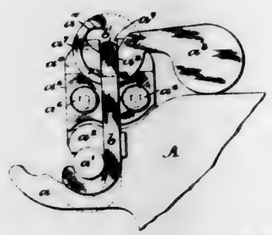
12. In a target apparatus, the combination with a penetrable target, and a universally-mounted pistol capable of being aimed at the target, of a carrier connected with the pistol-mounting and situated back of the target, a solenoid-coil mounted on said carrier, the pointed core 12 of said solenoid serving as an indicator for piercing the target, means for retracting said indicator, and an electric circuit including said solenoid-coil and a generator and adapted to be completed through pressure on the trigger of the pistol, substantially as set forth.

13. In a target apparatus, the combination with a penetrable target, and a universally-mounted pistol capable of being aimed at the target, of a carrier connected with the pistol-mounting and situated back of the target, the solenoid-coil fixed in said carrier, the pointed indicator, 12,

forming the movable core for the solenoid, means for retracting said core the locking-electromagnet, the plate 18, and an electric circuit including the coils of the solenoid and the locking-magnet and adapted to be completed through pressure on the trigger of the pistol, substantially as set forth.

14. In a target apparatus, the combination with a target, a universally-mounted pistol or arm capable of being aimed at any part of said target, a solenoid situated back of the target, means connecting said solenoid with the pistol whereby the solenoid is caused to move with the pistol when the latter is aimed, the core of said solenoid, adapted, when protruded to visually indicate its position on the target, and an electric circuit including said solenoid and a generator and adapted to be completed through pressure on the trigger of the pistol, substantially as set forth.

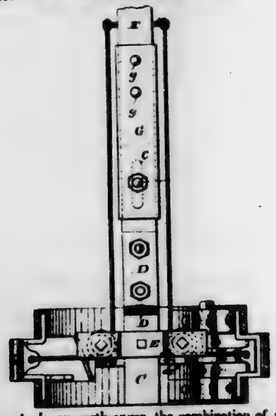
708,246. **BEAM-LOCK FOR LOOMS.** HENRY H. MCLEAN, Whitinsville, Mass., assignor to The Whitin Machine Works, Incorporated, Whitinsville, Mass. Filed Nov. 14, 1901. Serial No. 82,235. (No model.)



Claim.—1. The combination in a beam-lock with the end frame, the horn on the end frame forming the support for the beam-journal, the fixed journal-bearing, a slotted lug extending from the end frame, a bolster adjustably secured to the lug, of a lever, a cam on one end of the lever, concave seats within the cam, and two hooked arms connected by a bar, whereby the journal of the warp-beam may be supported and locked, as described.

2. In a beam-lock, the combination with the end frame A, the horn a, the fixed bearing a^3, and the lug a^2 on the end frame, of the bolster a^5, the lever a^6, the cam a^7 on the lever and supported on the bolster, the seats a^8 and a^{10} within the cam, the bar b', and the arms b b connected with the bar b' and having hooks at their ends, whereby the journal may be locked and held against vibration, as described.

708,247. **WELL-AUGER.** RALPH O. HEWELL, Venus, Nebr. Filed Dec. 1, 1899. Serial No. 738,939. (No model.)



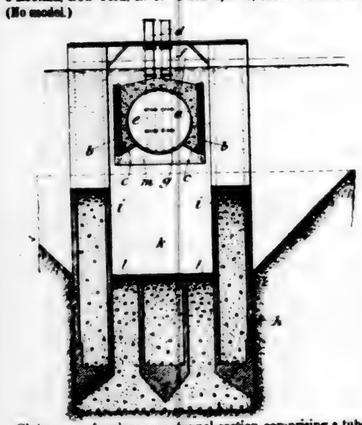
Claim.—1. In an earth-auger, the combination of an auger-drum, auger-blades supported upon and capable of radial movement relatively to said drum, springs connected with said blades and tending to give them outward radial movement, an auger-rod supporting said drum, the latter having a limited longitudinal movement upon said rod, and cords or chains connecting said rod and blades.

2. An earth-auger comprising the combination of a cylindrical drum having openings in its wall, auger-blades hinged in one end of said openings so as to swing outwardly, springs for effecting such outward movement, each blade provided with a stop adapted to limit such movement, an auger-rod attached to said drum and movable relatively thereto, and cords or chains connecting said rods and blades, whereby said rod may be caused to actuate said blades to withdraw from their outward positions.

708,248. **METHOD OF MOLDING ARTIFICIAL STONE.** FRANK OELIKOWSKI, Cleveland, Ohio. Filed May 14, 1902. Serial No. 107,264. (No specimens.)

Claim.—The method of making artificial stone consisting in placing within a suitable flask a compact layer of hard stone pieces; then covering said pieces at a suitable depth with a flowing cement, and then tamping the mass until solid; then spreading another close layer of hard stone pieces over said body to complete the stone and covering the same with cement to fill the interstices and overspread the same, and finally tamping the material thus added and leaving the stone with a flat finished top surface, substantially as described.

708,249. **SUBAQUEOUS-TUNNEL CONSTRUCTION.** JOHN F. O'ROURKE, New York, N. Y. Filed Apr. 23, 1902. Serial No. 104,284. (No model.)



Claim.—1. A subaqueous-tunnel section comprising a tube-section, bulkheads in the ends thereof, a sustaining vessel and filling between the walls of the sustaining vessel and the tube-section, substantially as described.

2. A subaqueous-tunnel section, comprising a tube-section, bulkheads in the ends thereof, a sustaining vessel comprising side walls and plates uniting the tube-section to said walls, and filling supported upon said plates between the tube-section and the side walls, substantially as described.

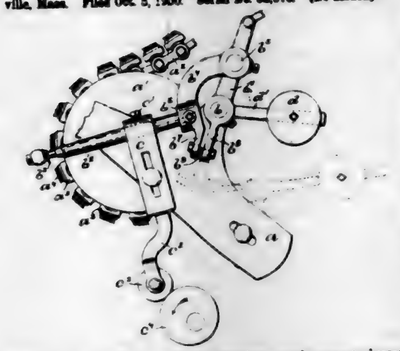
3. A subaqueous-tunnel section, comprising a tube-section, bulkheads in the ends thereof, a sustaining vessel for said tube-section, and a shaft extended through said tube-section to the bottom thereof, substantially as described.

4. A subaqueous-tunnel section, comprising a tube-section, bulkheads in the ends thereof, a sustaining vessel for said tube-section forming an air-chamber below the tube-section and a shaft extended through said tube-section to said air-chamber, substantially as described.

5. In subaqueous-tunnel construction, the combination of a crib or caisson sunk to the required depth and two tunnel-sections each comprising a tube-section and a sustaining vessel, said tunnel-sections having their ends brought together and supported upon the crib or caisson, and means to unite the ends of the tube-sections, substantially as described.

6. In subaqueous-tunnel construction, the combination of a crib or caisson sunk to the required depth, two tunnel-sections each comprising a tube-section and a sustaining vessel, the ends of the tunnel-sections being brought together within the crib, means to unite the tube-sections within the crib and concrete filling the space around the tube-sections within the crib or caisson, substantially as described.

708,250. **CARDING-MACHINE.** HENRY A. OWEN, Whitinsville, Mass., assignor to The Whitin Machine Works, Incorporated, Whitinsville, Mass. Filed Oct. 5, 1900. Serial No. 32,070. (No model.)



Claim.—1. A stripper mechanism having a comb-support pivotally connected with a rocking member, said member swinging on a point below the pivotal connection of the comb-support, and a link connection between the rocking member and the comb-support, whereby, for a limited part of the stroke of the comb, the comb-support may swing on its pivotal connection and then swing with the rocking member, as and for the purpose described.

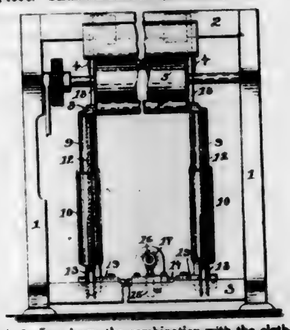
2. In a stripper mechanism for carding-machines, in combination, a rocking member, a comb-support pivotally connected with the rocking member, and means for limiting the movement of the comb-support on the rocking member, whereby the comb-support may swing on the rocking member, as described.

3. In a stripper mechanism for carding-machines, a comb-support having two pivotal points of support, means for limiting the movement of the comb on one of the points of support, and means for operating the comb, whereby the comb is moved diagonally from the normal path at each stroke, as described.

4. In a stripper mechanism for carding-machines, the combination with the comb b^3, and the supporting-arms b^2, of the arm b' pivotally supported on a fixed part of the machine, the bracket b^4, the link b^5, the bracket b^7, the supports b^1 pivotally supported on the arm b' and connected with the arm b', whereby the supports b^1 may rock on the pivotal connection through part of each stroke, as described.

5. In a stripper mechanism for carding-machines, the combination with the arm b' pivotally supported on a fixed part of the machine, the pivotal center b^4 on the arm, and the supports b^1 pivoted on the center b^4 and connected with the arm b' by a link connection, of the comb b^3, the arms b^2 supporting the comb, and means for operating the comb; whereby the comb is moved diagonally toward and from the wires of the flats at the beginning of each stroke, as described.

708,251. **LOOM.** OSCAR L. OWEN, Whitinsville, Mass., assignor to The Whitin Machine Works, Incorporated, Whitinsville, Mass. Filed Nov. 14, 1901. Serial No. 82,234. (No model.)



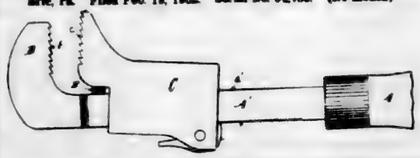
Claim.—1. In a loom, the combination with the cloth-roll, and the telescopic spring-actuated supports of the same, of a winding-shaft, sheaves on the same, cords connected with the cloth-roll supports and with the sheaves on the winding-shaft, and means, comprising a worm and worm-shaft, for operating the winding-shaft, as described.

2. A journal-support for the cloth-roll of a loom consisting of two tubular chambers, a tube sliding longitudinally in each tubular chamber, journal-supports on the free ends of the sliding tubes, coiled springs bearing on the bottom of the tubular chambers and the journal-supports on the sliding tubes, and cords connected with the sliding tubes and with a winding device, as described.

3. In a loom, the combination with the breast-beam, the front strut, the take-up roll, and the cloth-roll, of vertical struts secured to the breast-beam and the front strut, a tubular chamber forming part of each strut, tubes telescopically supported in the tubular chambers, journals bearing on the free ends of the tubes, a winding mechanism below the tubular chambers, and cords connected with the winding mechanism and the sliding tubes, as described.

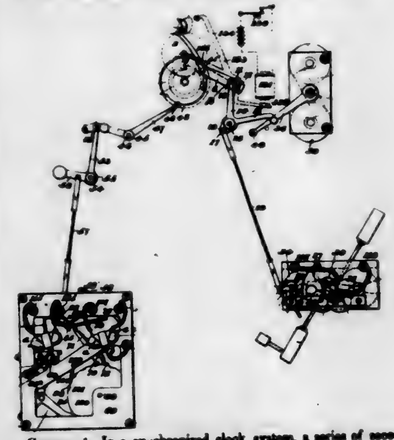
4. In a loom, the combination with the breast-beam, the take-up roll, the friction-roll, and the cloth-roll, of the arm 18, the tube 10, and the base 19 formed integral and secured to the breast-beam and the front strut, the tube 9, the journal-bearing 8 on the same, the cord 12 connected with the journal-bearing and with the winding-sheave 13, and mechanism for operating the two winding-sheaves of two journal-bearings simultaneously and comprising a worm and worm-gear, as described.

708,252. **PIPE-WRENCH.** FRANK A. PALMER and FRED SHARPE, Erie, Pa. Filed Feb. 19, 1902. Serial No. 94,759. (No model.)



Claim.—The combination in a pipe-wrench, of a handle, a serrated jaw thereon, ratchet-teeth on the under side of the handle, a sliding jaw-frame on the handle, a serrated jaw on the front end of the jaw-frame, spring-actuated mechanism in the front end of the jaw-frame engaging the upper side of the handle, and a cam-shaped ratchet-dog in the under side of the rear of the frame adapted to engage the ratchet-teeth on the under surface of the handle, substantially as and for the purpose set forth.

708,253. **ELECTRIC CLOCK.** ARTHUR F. POOLE, Wheeling, W. Va. Filed Sept. 7, 1901. Serial No. 74,653. (No model.)



Claim.—1. In a synchronized clock system, a series of secondary clocks, a master-clock having connections arranged to give electric impulses to them at determined intervals and for a determined period in one direction, and mechanism for sending out impulses for another period at determined intervals in the opposite direction; substantially as described.

2. In a synchronized clock system, a series of secondary clocks, a master-clock having connections arranged to give electric impulses to them at determined intervals in one direction, and for a predetermined period, and in the opposite direction at determined intervals and for a predetermined period, followed by a series of impulses in quick succession and in the same direction as the last preceding period, whereby the secondary clocks are synchronized; substantially as described.

3. In a synchronized clock system, a master-clock having connection with a series of secondary clocks arranged to give electric impulses to them at determined intervals in one direction and for a predetermined period, and in the opposite direction at determined intervals and for a predetermined period, followed by a series of impulses of augmented intensity in quick successions and in the same direction as the last preceding period, whereby the secondary clocks are synchronized; substantially as described.

4. In an electric clock, a switch normally locked, releasing mechanism adapted to unlock said switch so as to make and break the circuit at predetermined intervals; mechanism adapted to restore the releasing mechanism to its normal position, in which said switch is locked, said restoring mechanism being in the same circuit with said switch; substantially as described.

5. In an electric clock, a switch adapted to send out impulses at predetermined periods, releasing mechanism operated by the clock-movement adapted to unlock said switch at said predetermined interval, secondary clocks adapted to receive impulses sent out by said switch, mechanism adapted to restore the releasing mechanism to its normal position, in which said switch is locked and the circuit is broken, said restoring mechanism being in the same circuit with said switch and secondary clocks; substantially as described.

6. In an electric clock having a switch adapted to send out impulses at predetermined intervals, a synchroniser having switches adapted to change the direction of the impulses sent out by said switch; substantially as described.

7. In an electric clock having a switch adapted to send out impulses at predetermined intervals, a synchroniser having switches adapted to change the direction and intensity of the impulses sent out by said switch; substantially as described.

8. An electric clock having a switch adapted to send out impulses at predetermined intervals, a synchroniser having switches adapted to change the direction of said impulses, a cam operated by the clock mechanism and arranged to control the switches of the synchroniser, thereby determining the period during which impulses are sent out in a given direction; substantially as described.

9. In an electric clock having a switch adapted to send out impulses at predetermined intervals for predetermined periods and in quick succession for another period relatively short, releasing mechanism controlling said switch, a restorer normally adapted to reset said releasing mechanism and lock said switch after each impulse during the longer periods, a synchroniser having switches adapted to change the direction of the current during the long periods, said restorer being normally in circuit with the switch which sends out impulses at predetermined intervals, but adapted to be cut out of said circuit by one of the switches of the synchroniser during the relatively short period during which said switch which sends out impulses, so that said switch is permitted to send out a series of impulses in quick succession; substantially as described.

10. In an electric clock having a switch adapted to send out impulses at predetermined intervals, a synchroniser having switches adapted to change the direction of the impulses sent out by said switch, releasing mechanism operated by the clock mechanism by which the interval at which said impulses are sent out is determined, a synchroniser having switches adapted to change the direction of said impulses, a cam operated by the clock mechanism arranged to control the switches of the synchroniser, thereby determining the period during which impulses are sent out in a given direction; substantially as described.

11. In an electric clock provided with a switch adapted to send out impulses, a synchroniser having switches arranged to form a portion of a path for said impulses, said synchronizing-switches being adapted to change the direction in which said impulses are sent out; electromagnets forming a part of the circuit and adapted to offset the restoration of said switches to their normal position on the back stroke of their armatures; substantially as described.

12. In an electric clock having a switch adapted to send out impulses at predetermined intervals, a synchroniser having switches released in succession, mechanism operated by the clock mechanism by which said release is effected, said switches when released altering the direction in which the impulses are sent out, electromagnets located in circuit with said switches adapted to restore them to their normal position in the reverse order to which they were released upon the back stroke of the armatures; substantially as described.

13. In an electric clock having a switch adapted to send out impulses at predetermined intervals, a synchroniser having switches released in succession, mechanism operated by the clock mechanism by which said release is effected, said switches when released altering the direction in which the impulses are sent out, electromagnets located in circuit with said switches adapted to restore them to their normal position upon the back stroke of the armatures; substantially as described.

14. In an electric clock having a switch adapted to send out impulses at predetermined intervals released by the clock mechanism, a synchroniser having a switch also released by said clock mechanism, said switch being adapted when released to change the direction without altering the interval at which said impulses are sent out; substantially as described.

15. In an electric clock having a switch adapted to send out impulses at predetermined intervals released by the clock mechanism, a synchroniser having a switch also released by said clock mechanism, said switch being adapted when released to change the direction without altering the interval at which said impulses are sent out, and a second switch adapted to be released by said clock mechanism after the first switch has been released, whereby the frequency of the impulses sent out is permitted until said switch is returned to its normal position; substantially as described.

16. In an electric clock having a switch adapted to send out impulses at predetermined intervals released by the clock mechanism, a synchroniser having a switch also released by said clock mechanism, said switch being adapted when released to change the direction without altering the interval at which said impulses are sent out, a second switch adapted to be released by said clock mechanism after the first switch has been released, whereby the frequency of the impulses sent out is permitted, and a locking-disk provided with a series of notches arranged at intervals, an electromagnet in circuit with the impulse-sending switch and said second switch of the synchroniser, feeding mechanism actuated by said electromagnets, whereby said locking-disk is fed step by step, resetting mechanism for said second switch which is held out of operative position during the interval between the notches in said locking-disk, said switch being returned to its normal position when the resetting mechanism again engages the next succeeding notch in the locking-disk; substantially as described.

17. In an electric master-clock having a switch adapted to send out impulses at predetermined intervals, a releasing mechanism therefor, a restorer for said switch in circuit therewith, a synchroniser having switches adapted to change the direction and intensity of said impulses, electromagnets having vibrating armatures adapted to restore said switch, resetting mechanism secured to said armatures, clock mechanism adapted to determine the time at which said change of direction and intensity takes place, releasing mechanism operated by said clock mechanism by which said synchroniser-switches are released in succession, one of said switches altering the direction of the impulses sent out without affecting the intensity of the current, the second switch of said synchroniser being adapted to increase the intensity of the current without changing its direction, said second switch permitting the repeating-switch to send out impulses of augmented intensity in rapid succession, feeding mechanism actuated by the vibrating armature of one of said electromagnets, releasing mechanism whereby said synchronizing-switches are operated, also actuated thereby, said armature resetting said releasing mechanism for both switches on its first feeding stroke, a locking-disk adapted to be actuated by said feeding mechanism, notches in the periphery of said locking-disk arranged at intervals, resetting mechanism for said second switch adapted to engage the notches and the periphery of said locking-disk, the space between said notches determining the number of impulses of augmented intensity sent out by the repeating-switch in quick succession, said second switch with the synchroniser being restored to its normal position on the first back stroke of the electromagnet which operates the locking-disk when the resetting mechanism is dropped into registry with the next succeeding notch, the resetting of said switch again completing the circuit through the restorer for the repeating-switch, and thereby establishing the circuit through the magnet of the synchroniser-switch first released, and thereby actuating its armature and the resetting mechanism secured thereto so that upon the back stroke of the armature, the first-released switch of the synchroniser is returned to its normal position; substantially as described.

18. A synchronized clock system comprising a primary clock having connection with a self-driven master-clock, mechanism by which said master-clock is synchronized therewith, said master-clock having connections with a series of secondary clocks arranged to give electric impulses to them at determined intervals and for determined periods in one direction, and mechanism for sending out impulses for another period and a determined interval in the opposite direction, whereby said secondary clocks are synchronized with said master and primary clock; substantially as described.

708,254. TURBINE FLUE-CLEANER. JOHN P. PRESTON and ROBERT G. GREGORY, Barberton, Ohio, assignors to the Stirling Company, Chicago, Ill., a Corporation of Illinois. Filed July 17, 1901. Serial No. 68,020. (No model.)

Claim.—1. In a boiler-tube cleaner, the combination with a casing having a tapered portion provided with a restricted opening, of a hose or tube projecting into said tapered portion, a bushing or thimble fitting within said tube or hose and clamping the same against the inner wall of the tapered portion, a perforated disk in said casing adjacent to the forward end of the bushing or thimble and provided with a rearward-tapered portion projecting into said bushing, a motor-wheel mounted on said disk, and a tube-cleaning tool connected to said wheel.

2. In a boiler-tube cleaner, the combination with a casing having a tapered portion provided with spiral grooves or recesses on its inner face, of a hose or tube projecting into said tapered portion, a bushing or thimble fitting within said tube or hose and provided with spiral ribs which press the tube out into the holes or depressions in the casing, a perforated disk in said casing adjacent to the forward end of said bushing or thimble and provided with a rearward-tapered portion projecting into said bushing, a motor-wheel mounted on said disk, and a tube-cleaning tool connected to said wheel.

3. In a boiler-tube cleaner, the combination with a casing having a tapered portion at one end, of a hose or tube projecting into said tapered portion, an internal flange on the casing against which the end of the tube projects, a tapered thimble or bushing fitting within the tube and serving to clamp the same against the inner wall of the tapered portion, a perforated stationary disk adjacent to the end of the bushing and internal flange, a turbine wheel rotatably mounted in said casing, and a tube-cleaning tool connected to said wheel.

4. In a boiler-tube cleaner, the combination with a casing, a perforated disk fixedly mounted therein and provided with a rearwardly-tapered projection, a turbine wheel rotatably mounted on said disk, a tube-cleaning tool connected to said wheel, a tapered portion of said casing provided with an internal flange or shoulder so arranged as to leave a space between the same and the perforated disk, a hose or tube projecting into the casing against said flange or shoulder, and a tapered bushing fitting within said tube or hose and clamping the same against the inner wall of the casing.

5. In a boiler-tube cleaner, the combination with a casing provided with an internal shoulder and internal screw-threads, a perforated disk therein resting against said shoulder, a tapered extension having a threaded portion engaging the internal threads in the casing and bearing against the disk to clamp the same against the internal shoulder, a hose or tube projecting into said extension, a tapered bushing or thimble fitting within the hose, a turbine wheel rotatably mounted on said perforated disk, and a tube-cleaning tool connected to said wheel.

6. In a boiler-tube cleaner, the combination with a casing provided with an internal shoulder and internal screw-threads, a perforated disk in said casing resting against said shoulder, said disk being provided with a rearwardly-projecting conical portion, a tapered extension having a threaded portion engaging the internal threads in the casing and bearing against the perforated disk to clamp the same against the internal shoulder, said extension being provided with an internal flange or shoulder, a hose or tube projecting into the extension and against said flange or shoulder, a conical bushing or thimble fitting within the hose or tube and serving to clamp the same against the inner wall of said extension, a motor-wheel rotatably mounted on said perforated plate, and a tube-cleaning tool connected to said wheel.

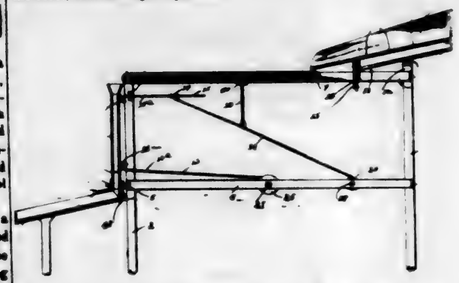
7. In a boiler-tube cleaner, a fluid-motor comprising a stationary perforated disk having a central opening, a motor-wheel provided with a central opening and a screw-threaded socket in one face thereof, a journal-pin having a head located in said socket and secured in the opening in the stationary disk, a tool-carrying block provided with a threaded extension engaging the screw-threaded socket in the wheel, said extension being recessed to fit over the head of the screw, and a tube-cleaning tool attached to said block.

708,255. CRACKER-STACKING MACHINE. BURT PRESCOTT and WILLIAM H. BUDD, Jr., Columbus, Ohio. Filed Apr. 4, 1902. Serial No. 101,228. (No model.)

Claim.—1. In a cracker-stacking machine, the combination with a framework and a hopper pivotally mounted thereon, of cracker-conducting tubes movably connected with said framework and a cracker-carrying mechanism arranged between said hopper and the mouths of said tubes, substantially as specified.

2. In a cracker-stacking machine, the combination with a framework and a grooved table arranged adjacent thereto, of a plurality of tubes having their lower ends beveled or inclined and extending within said table-grooves and means for imparting a swinging motion to said tubes, substantially as specified.

3. In a cracker-stacking machine, the combination with a framework, and a grooved table arranged adjacent thereto, of a plurality of cracker-conducting tubes having their lower end portions extending within the grooves of said table and having said lower end portions beveled as described, a finger extending outwardly from each of said tubes and adapted when said tubes are in a vertical or substantially vertical position to engage the upper portion of a cracker arranged on edge within the groove of said table and means for imparting a swinging movement to the tubes, substantially as specified.



4. In a cracker-stacking machine, the combination with a framework and a grooved table arranged adjacent thereto, of a plurality of cracker-conducting tubes having their lower beveled ends discharging within the grooves of said table, means connected with the lower portions of said tubes for imparting a swinging motion thereto and means for imparting a vibratory motion to the tubes, substantially as specified.

708,256. BRICK-MOLD. OTTO M. REIF, Allegheny, Pa., assignor to Harbison & Walker Company, Pittsburg, Pa., a Corporation of Pennsylvania. Filed Mar. 21, 1901. Serial No. 52,182. (No model.)

Claim.—1. A brick-mold comprising sides formed of angle-irons, the vertical flanges of which form the side walls of the mold and the other flanges of which lie in a horizontal plane, transverse end pieces separate from and riveted to said vertical flanges, and a bottom secured to said horizontal flanges.

2. A brick-mold comprising side pieces formed of angle-irons, the vertical flanges of which form the side walls of the mold, transverse end pieces and partitions separate from and permanently attached to said vertical flanges, the horizontal flanges of said angle-irons extending the full length of the mold, and a bottom secured to said horizontal flanges.

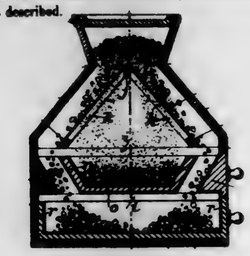
3. A brick-mold comprising side pieces formed of angle-irons, the vertical flanges of which form the side walls of the mold, and the other flanges of which lie in a horizontal plane, and a bottom having an inclined upper face and parallel side edges secured to said horizontal flanges.

4. A brick-mold comprising side pieces formed of angle-irons, the vertical flanges of which form the side walls of the mold, inclined transverse end pieces and partitions secured to said vertical flanges, the horizontal flanges of said angle-irons extending the full length of the mold, and a bottom having a series of inclined faces on its upper surface and parallel side edges secured to said horizontal flanges.

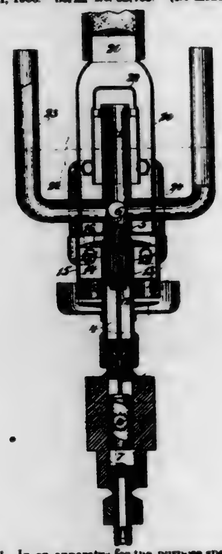
708,257. ASH-SIFTER. ALBERT L. RUSSELL, Providence, R. I., assignor of one-half to Earl G. Davis, Plainfield, Conn. Filed Oct. 23, 1901. Serial No. 80,334. (No model.)

Claim.—In an ash-sifter, the combination, with a casing the upper portion of which has inclined end walls, of a cuneiform screen the sides of which are parallel with but separate from the inclined walls of the casing, an ash-drawer beneath the screen, said drawer having a chute in its forward end and an ash-compartment in rear of said chute, and a cinder-drawer beneath the ash-drawer, said cinder-drawer being of such

length as to underlie the chute and extend beyond the ash-compartment substantially as described.



708,258. APPARATUS FOR BURNING LIQUID HYDROCARBONS. WILLIAM H. RUSSELL and GEORGE E. RUSSELL, Jersey City, N. J. Filed Oct. 11, 1900. Serial No. 33,703. (No model.)



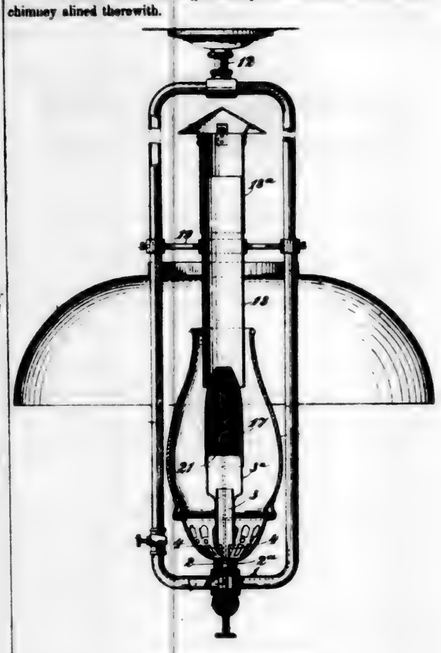
Claim.—1. In an apparatus for the purpose specified, the combination with a generator and means for admitting oil in regulated quantity thereto, of a mixing-tube above the outlet of the generator, an intermediate tube closed above and over the upper end of the mixing-tube, an air-induction pipe which admits air to said mixing-tube, an outer casing inclosing the mixing-tube and intermediate tube, a casing about the generator to form a heating-chamber, a tube connecting the chamber in the outer casing with the heating-chamber, the receiving end of said tube being situated above the lower, open end of the intermediate tube, and a receptacle below the heating-chamber to contain a combustible for igniting the gaseous mixture in the heating-chamber, substantially as set forth.

2. In an apparatus for the purpose specified, the combination with a generator and means for admitting oil thereto, of a casing about said generator and having apertures in its bottom, a baffle-plate below said casing, a cup for combustible liquid below said plate, gauze diaphragms within said casing, an outer casing, which carries the burner-tube and is mounted on the casing surrounding the generator, tubes connecting said casings, a mixing-tube within the outer casing, air-tubes connected with and supplying said mixing-tube, an intermediate tube within the outer casing and inclosing the mixing-tube, and means for regulating the outflow of gas from the generator, substantially as set forth.

708,259. BUNSEN BURNER. WILLIAM H. RUSSELL and GEORGE E. RUSSELL, Jersey City, N. J. Filed Dec. 2, 1901. Serial No. 84,350. (No model.)

Claim.—1. A Bunsen burner having an elongatable burner-tube, means for supplying gas thereto, a telescopic chimney, a bar carrying said chimney and upright parallel guides for said bar, substantially as set forth.

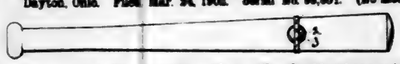
2. A Bunsen burner having a telescopic burner-tube and a telescopic chimney alined therewith.



708,260. STAIR-PAD. HERBERT H. SANDERSON, Walpole, Mass. Filed June 24, 1901. Serial No. 65,751. (No model.)

Claim.—As an article of manufacture, a stair-pad, composed of a base, a fabric stitched along its edges to the base on the under side thereof, along a longitudinal line extending from one end of the base to the other, the fabric extending from said line of stitching over the front and rear edges of the base and over the upper surface of the base, whereby the meeting edges of the covering are secured to the under side of the base along said longitudinal row of stitching, a soft filling between the top of the base and the upper layer of covering fabric, and a transverse row of stitching through the upper and lower layers of covering fabric and through the base along each end edge of the base, substantially as set forth.

708,261. BALL-BAT AND EXPLOSIVE. JOHN C. SCHWABENGEL, Dayton, Ohio. Filed Mar. 24, 1902. Serial No. 99,051. (No model.)



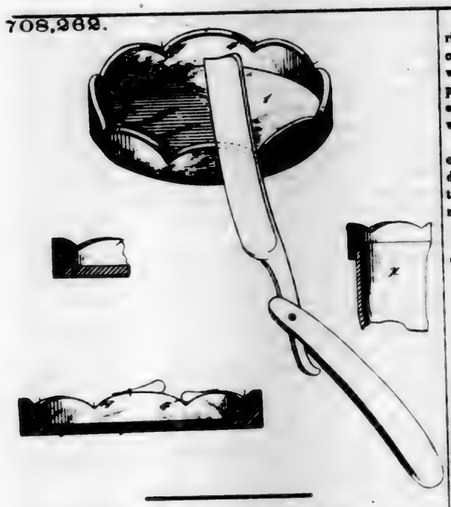
Claim.—A ball-bat provided with an orifice shouldered and reduced at its inner end and adapted to contain a cartridge, in combination with an exploding-hammer in the outer end of said orifice, and an elastic retaining means for said hammer, substantially as described.

708,262. RAZOR-CLEANER. HENRY SCHWEITZER, Altoona, Pa. Filed May 2, 1902. Serial No. 105,691. (No model.)

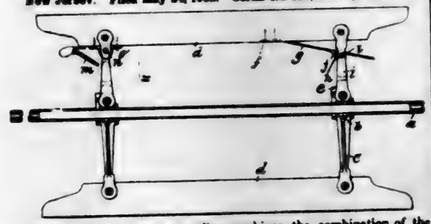
Claim.—1. A razor-cleaner comprising a cup-like body of which the vertical flange portion is formed of a yielding material, the upper edge of the flange being escalloped to form curved surfaces adapted to fit the concaved sides of a razor-blade.

2. A razor-cleaner comprising a cup-like body of which the vertical flange portion is formed of thick yielding material, said flange portion having an escalloped upper edge, the curved surfaces being each formed on arcuate lines of different radii and adapted to fit into the concave or semi-concave sides of razor-blades.

708,262.



708,263. REEL. JAMES SHAW, Paterson, N. J., assignor to the Shaw & Cocker Machine Company, Paterson, N. J., a Corporation of New Jersey. Filed May 24, 1902. Serial No. 108,943. (No model.)



Claim.—1. In a reel for reeling-machines, the combination of the spiders, a blade, the spokes of said spiders which carry the blade serving as link-like connections between the spiders and the blade, and a spring-latch adapted to secure said blade and one of said spokes in their extended positions and carried by one and engageable with the other of them, substantially as described.

2. In a reel for reeling-machines, the combination of the spiders, a blade, the spokes of said spiders which carry the blade serving as link-like connections between the spiders and the blade, and a spring-latch carried by said blade and engageable with one of said spokes in the extended position of the blade, substantially as described.

708,264. BOTTLE-STOPPER. WILLIAM H. SHERMAN, New York, N. Y. Filed July 3, 1901. Serial No. 66,977. (No model.)

Claim.—1. A bottle-stopper comprising a soft-metal cup fitted to be locked in the neck of the bottle, a releasing-plug and means for drawing the cup into locking engagement with the plug as the plug is forced inwardly to release the cup from the bottle, substantially as set forth.

2. A bottle-stopper comprising a soft-metal cup having its walls struck outwardly to engage the neck of a bottle, a releasing-plug having a circumferential groove therein and means for drawing the cup into locking engagement with the plug as the plug is forced inwardly to release the cup from the bottle, substantially as set forth.

3. A bottle-stopper comprising a soft-metal cup having its walls struck outwardly to engage the neck of a bottle and having an outwardly-flaring rim and a releasing-plug having a circumferential groove, the said cup and releasing-plug being fitted to be locked together when the cup is released from the bottle by the said plug, substantially as set forth.

4. In combination, a bottle having an annular shoulder in the interior of its neck and a tapering seat in the mouth of the neck, a soft-metal cup having one or more projections engaging the said shoulder and an outwardly-flared rim and a releasing-plug arranged to draw the one or more projections out of engagement with the shoulder and the flaring rim into engagement with the plug when the plug is driven to the limit of its inward movement within the neck of the bottle, substantially as set forth.

5. A bottle-stopper comprising a soft-metal cup locked in the neck of the bottle and having a corrugated rim and releasing-plug arranged to draw the corrugated rim into locking engagement with the plug when the plug is inserted into the cup and driven to the limit of its inward movement within the neck of the bottle, substantially as set forth.

708,265. PLOW. JACOB A. SHUPING and CHARLES L. SHUPING, Morganton, N. C. Filed Aug. 28, 1901. Serial No. 73,621. (No model.)

Claim.—1. In a disk plow, the combination with a base, of means located upon one side of the base for securing the same to a beam or similar support, an adjustable disk-carrier movable in a vertical plane and journaled upon the opposite sides of the base, a disk mounted upon the carrier, and means connecting the base and disk-carrier to hold the latter against its vertical swinging movement.

2. In a disk plow, the combination with an upright base having a slot that passes horizontally through said base, of means for attaching the base to a beam or similar support, a disk-carrier movably mounted on the base, and a holding device for the disk-carrier, said device being mounted upon the disk-carrier and engaging in the slot of the base whereby said carrier may be adjusted in a vertical plane.

3. In a disk plow, the combination with an upright base-plate having a slot that passes horizontally through said base-plate, of a clamp for attaching the base-plate to a plow-beam or similar support, an eyebolt pivotally mounted upon the plate, an eyebolt movably mounted in the slot, and a disk-carrier passing through the eyebolts and being thereby adjustable in a vertical plane.

4. In a disk plow, the combination with a vertically-disposed base-plate having a horizontally-disposed slot in its lower portion and a pivot-opening in its upper portion, of a clamp located upon one face of the plate for attaching the same to a plow-beam or similar support, an eyebolt pivoted in the upper opening of the plate, an eyebolt movably mounted in the slot, and a disk-carrier passing through the eyebolts whereby said carrier may be adjusted in a vertical plane.

5. In a disk plow, the combination with a disk-carrier, of means for securing the carrier to a plow-beam or similar support, said carrier having a movable connection with the securing means, and an extensible holding device fastened to the carrier to hold the same against movement.

6. In a disk plow, the combination with a disk-carrier, of means for securing the same to a plow-beam or similar support, said carrier having a rotatable connection with the said means, and an extensible holding device fastened to the carrier for holding the same against movement.

7. In a disk plow, the combination with a base, of means for securing the same to a beam or similar support, a disk-carrier shaft rotatably mounted on the base, and an adjustable holding device secured to the shaft and arranged to be fastened to a portion of the plow to hold said shaft against movement.

8. In a disk plow, the combination with a base, of means for securing the same to a beam or similar support, a disk-carrier shaft rotatably mounted on the base and provided with a crank-arm, and an extensible holding device connected to the crank-arm for holding the shaft in different positions.

9. In a disk plow, the combination with a plow beam and handle, of a disk-carrier rotatably mounted on the beam, and an extensible connection between the carrier and handles to hold the former against movement.

10. In a disk plow, the combination with a plow beam and handles of a disk-carrier shaft rotatably mounted on the beam and having a crank-arm, a holding-rod connecting the crank-arm and the handles and comprising sections, and a turnbuckle adjustably connecting the adjacent ends of the sections.

11. In a disk plow, the combination with a base, of means for securing the base to a plow-beam or similar support, a disk-carrier having a pivotal and rotatable connection with the base, a holding device carried by the base for preventing the pivotal movement of the carrier, and means for holding said carrier against rotary movement.

12. In a disk plow, the combination with a base, of means for se-

curing the base to a plow-beam or similar support, a disk-carrier having a horizontal pivotal and a vertical rotatable connection with the base, a holding device carried by the base for preventing the pivotal movement of the carrier, and means for holding said carrier against rotary movement, said means being located adjacent to the pivotal connection between the carrier and the base.

13. In a disk plow, the combination with a vertically-disposed base-plate, of a clamp for attaching the plate to a beam or similar support, a pair of horizontally-projecting eyebolts secured to the plate, one of said bolts having a slidable connection therewith, a disk-carrier shaft journaled in the eyebolts and having a crank-arm and an extensible holding device secured to the crank-arm.

14. In a disk plow, the combination with a base, of alined bearings movably mounted upon the base, and a disk-carrier journaled in the bearings and longitudinally adjustable therein.

15. In a disk plow, the combination with a vertically-disposed base, of horizontally-projecting alined bearings movably mounted upon the base a disk-carrier journaled in the bearings and longitudinally adjustable therein, and devices engaging the outer sides of the journals to hold the carrier against its longitudinal movement.

16. In a disk plow, the combination with a vertically-disposed base, of horizontally-projecting alined bearings movably mounted upon the base, a disk-carrier journaled in the bearings and longitudinally adjustable therein, devices engaging the outer sides of the journals to hold the carrier against its longitudinal movement, one of said devices being in the form of a crank-arm, and means engaging said crank-arm to prevent the rotation of the carrier in the journal.

17. In a disk plow, the combination with a disk-carrier, of means for securing the same to a beam or similar support, said carrier having a vertical longitudinal adjustment upon the securing means, a head attached to the carrier, a disk rotatably mounted on the head, and a scraper also secured to the head.

18. In a disk plow, the combination with a disk-carrier, of a head located upon the carrier and having an annular bearing-flange, a disk-bearing carrying the disk and having spaced flanges that embrace the flange of the head, the inner flange being spaced from the adjacent face of the head, and a pivot fastener passing through the head and disk-bearing.

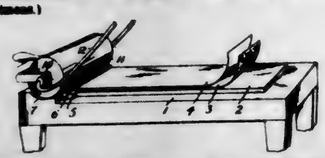
19. In a disk plow, the combination with a disk-carrier, of a head located upon the carrier and having an annular bearing-flange, said carrier being also provided with a scraper-support, a disk-bearing carrying the disk and having spaced flanges that embrace the flange of the head, a pivot fastener passing through the head and disk-bearing, and a scraper secured to the support of the carrier-head.

20. In a disk plow, the combination with a suitable frame, of a rotatable disk-carrier journaled upon the frame, extensible means secured at one end to a fixed portion of the frame, and at the other end to the carrier for holding said carrier against its rotary movement.

21. In a disk plow, the combination with a fixed support, of journal-bearings mounted upon the support and movable in a substantially vertical plane, and a disk-carrier journaled in the bearings and rotatable upon a substantially vertical pivot-axis.

22. In a disk plow, the combination with a beam having a channel, of a base-plate having a projection fitting in the channel, means for securing the base-plate upon the beam, and a disk-carrier rotatably mounted upon the base-plate.

708,266. DECORATION OF WOODWORK. HENRY SMITH, Kew, Victoria, Australia. Filed May 23, 1901. Serial No. 61,602. (No specimens.)



Claim.—1. The method or process of ornamenting wood, which consists in treating the smoothed surface of wood with kerosene and crystal paper-varnish, then applying wetted paper on which is a design made with oil or spirit colors with face of paper onto the wood, then applying pressure and heat to the paper whereby the design on the paper is caused to impregnate or be incorporated into the wood.

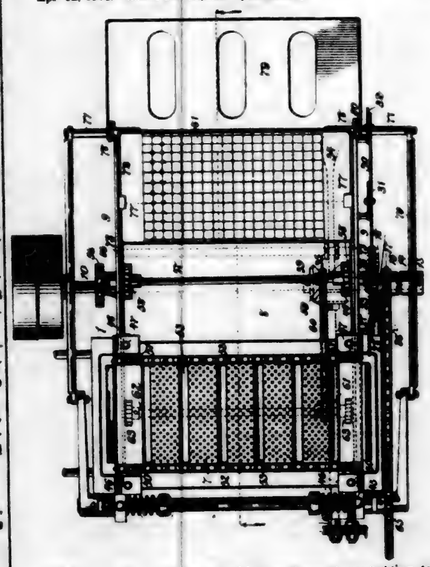
2. The method or process of ornamenting wood which consists in treating the smoothed surface of wood with kerosene and crystal paper-varnish, then applying wetted paper on which is a design made with oil or spirit colors with the face of paper on the wood, then applying a damp cloth to back of paper, then applying pressure to the damp cloth by means of a heated iron or roller substantially as described.

3. The method or process of ornamenting wood which consists in treating smoothed surface of wood with kerosene and crystal paper-varnish, then applying wetted paper on which is a design made with oil or spirit colors with the face of paper on the wood, then applying a damp cloth to back of paper, then applying pressure to the damp sheet by means of a heated iron or roller, then, after the design has dried on the wood, applying size and afterward varnish or polish substantially as described.

4. The method or process of ornamenting wood, which consists in treating smoothed surface of wood first with a coating of whiting and milk solution and afterward with a solution of kerosene and crystal paper-varnish, then applying wetted paper, on which is a design made with oil or spirit colors, to the surface of the wood, then applying at back of paper a damp cloth, preferably of cotton, then applying an even pressure over the cotton sheet by means of a heated household iron or a roller, then allowing the surface of the wood with the design to dry, then sizing and afterward varnishing or polishing the surface substantially as described.

5. The method or process of ornamenting wood which consists in treating smoothed surface of wood first with a coating of whiting and afterward treating the wood surface with a solution of kerosene and crystal paper-varnish, applying to the surface of the wood a wall-paper prepared with oil and spirit colors and coated with a solution of methylated spirits and water then applying to back of paper a damp cloth then applying an even pressure over the cloth by means of a heated iron substantially as and for the purpose set forth.

708,267. COATING-MACHINE. MYRON A. SMITH, New York, N. Y., assignor to International Machine Co., New York, N. Y. Filed Apr. 12, 1901. Serial No. 55,453. (No model.)



Claim.—1. The combination with a coating-material-holding tank and a perforated distributer mounted thereover, of elevator-buckets arranged to raise coating material from the tank, empty it upon one end of the distributer and spread it over the entire surface thereof, substantially as shown and described.

2. The combination with a coating-material-holding tank and a perforated distributer mounted thereover, of elevator-buckets arranged to raise the coating material from the tank, empty it upon one end of the distributer and spread it over the surface thereof, and a reciprocatable center-carrying device, substantially as shown and described.

3. The combination with a coating-material-holding tank and a perforated distributer mounted thereover, of elevator-buckets arranged to raise the coating material from the tank, empty it upon one end of the distributer and spread it over the surface thereof, a reciprocatable center-carrying device, and means for jarring or shaking the same when beneath the coating-material distributer, substantially as shown and described.

4. The combination with the material-holding tank, applying mechanism, and horizontally-reciprocatable center-carrying device, of a drip-pan at the front of the tank, means for automatically moving the center-carrier over the drip-pan, and means for automatically jarring or shaking the center-carrying device when over said pan, substantially as shown and described.

5. The combination with the main driving-shaft carrying a clutch, of driving mechanism connected with the free portion of the clutch and the mechanism for reciprocating the center-carrier, the center-carrier, and means for automatically stopping the center-carrier over the coating-tank, and over the drip-pan, substantially as shown and described.

6. The combination with the main driving-shaft carrying a clutch, of driving mechanism connected with the free portion of the clutch and the mechanism for reciprocating the center-carrier, the center-carrier, and means for automatically stopping the center-carrier over the coating-tank, over the drip-pan, and at the outer end of the stroke, substantially as shown and described.

7. The combination with the main driving-shaft carrying a clutch, of driving mechanism connected with the free portion of the clutch and the mechanism for reciprocating the center-carrier, the center-carrier, and means for automatically stopping the center-carrier over the coating-tank, over the drip-pan and at the outer end of the stroke, and for locking the same at the end of each stroke, substantially as shown and described.

8. The combination with the main driving-shaft provided with a clutch, and with the reciprocatable center-carrier, of a treadle for throwing the clutch into operation, and automatic means for throwing it out of operation at three points in the reciprocation of the center-carrier, substantially as shown and described.

9. The combination with a loose collar upon the driving-shaft, a clutch mechanism also on said shaft for controlling the same, of connections between the collar and a stop upon the main frame arranged to engage the driving-wheel of the center-carrying mechanism, substantially as shown and described.

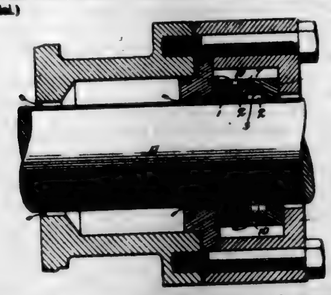
10. The combination with the center-carrying frame provided with projections at each side, of the adjustable supporting-bars upon which said frame rests and moves, and ratchet-wheels arranged to come in contact with said projections, substantially as shown and described.

11. The combination with the reciprocatable center-carrying frame and means for reciprocating the same, of arms thereon, slotted plates at the end of the outward stroke adapted to receive said arms, substantially as and for the uses and purpose shown and described.

12. The combination with the reciprocatable center-carrying frame and means for reciprocating the same, of arms thereon, slotted plates fixed to the main frame at the end of the outward stroke adapted to receive said arms, and a fly hinged upon said slotted plates adapted and arranged to turn independently or in unison with the center-carrying frame, substantially as shown and described.

13. The combination with the center-carrying frame of a center-holder the receptacles wherein are provided with imprinting devices adapted and arranged to be held out of contact with the centers while they are being coated and brought in contact with the coated surfaces when the center-holder is reversed for depositing the coated goods, substantially as shown and described.

708,268. METALLIC PACKING. THOMAS SMITH, San Luis Potosi, Mexico, assignor of two-thirds to C. B. Haag and R. M. Thomas, San Luis Potosi, Mexico. Filed July 2, 1901. Serial No. 66,334. (No model.)



Claim.—1. The combination with a piston-rod, of a segmental packing normally loose thereon, means for holding the packing assembled and means whereby when fluid-pressure is on the cylinder the packing will be brought into positive engagement with the rod.

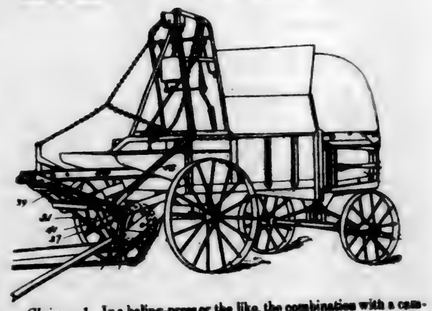
2. The combination with a piston-rod, of a plurality of sectional packing-rings normally loose thereon, means for holding the rings assembled and means whereby when fluid-pressure is on the cylinder the rings will be brought into positive engagement with the rod.

3. The combination with a piston-rod, of a metallic sectional packing comprising a plurality of packing-rings normally loose upon the piston-rod, and a casing for holding the rings assembled, the said casing having a fluid-space exterior of the packing-rings and communicating with the interior of the cylinder, whereby when the cylinder is under pressure, the rings will operatively engage the piston-rod, and when the cylinder is relieved from pressure, the rings will be loose thereon.

4. A packing of the class described, comprising a plurality of fluid-pressure-actuated radially-variable packing-rings encompassing the piston-rod and normally out of frictional engagement therewith, but adapted to bear frictionally on the piston-rod with a pressure varied by that of the internal fluid-pressure in the cylinder, and a casing in which said packing-rings are confined, said casing having a fluid-space exterior of the packing-rings and communicating with the interior of the cylinder, whereby when the latter is relieved of internal fluid-pressure the friction between the packing-rings and the piston-rod is relaxed, substantially as described.

5. A packing of the class described, comprising fluid-pressure-actuated radially-variable packing-rings encompassing the piston-rod and normally out of frictional engagement therewith, but adapted to bear frictionally on the same with a pressure varied by that of the internal fluid-pressure in the cylinder, and a casing in which said packing-rings are confined, said casing having a fluid-space, exterior of the packing-rings and communicating with the interior of the cylinder, whereby when the latter is relieved of internal fluid-pressure, the friction between the packing-rings and the piston-rod is relaxed, substantially as described.

708,269. BALING-PRESS. JULIUS A. STRECKER, Dwight, Ill. Filed Oct. 28, 1901. Serial No. 80,272. (No model.)



Claim.—1. In a baling-press or the like, the combination with a cam-block adapted to be continuously rotated and a traveler connected to the follower of the press and slidable on the periphery of the cam-block, of a longitudinally-movable locking-bolt for the traveler carried by the cam-block and provided with a lateral extension, a fixed cam adapted to engage the lateral extension of said bolt and actuate the latter through its unlocking movement, and an arm pivoted to said lateral extension and to the body of the cam-block and serving to counteract that component of the cam's action which is transverse to the bolt, substantially as described.

2. In a baling-press or the like, the combination with a rotatable cam-block and a traveler connected to the follower of the press and slidable on the periphery of the cam-block, of a longitudinally-movable locking-bolt for the traveler housed in the cam-block and provided with a vertical extension, a fixed cam having two cam-faces adapted to engage the vertical extension of said bolt on opposite rotative movements of the cam-block, respectively, and actuate said bolt through its unlocking movement, and an arm pivoted to said vertical extension and to the body of the cam-block and serving to counteract that component of the cam's action which is transverse to the bolt, substantially as described.

3. In a baling-press or the like, the combination with a cam-block adapted to be continuously rotated and a fixed track disposed adjacent said cam-block and on the arc of a circle whose center is coincident with the pivotal axis of the cam-block, said track having one end thereof abruptly curved outwardly, of a traveler connected to the follower of the press and slidingly engaging said track, and a fixed projection on the cam-block adapted to advance the traveler along the track, the latter, when it reaches the outwardly-curved end of the track passing out of contact with the projection, substantially as described.

4. In a baling-press or the like, the combination with a continuously-rotatable cam-block and a fixed track disposed above said cam-block and on the arc of a circle whose center is coincident with the pivotal axis of the cam-block, said track having one end thereof abruptly curved outwardly, of a depending traveler slidingly engaging said track, a power-transmitting connecting-rod swiveled to the under side of said traveler said rod having a depending leg, and a fixed arm projecting radially from

the periphery of the cam-block and adapted to contact said lug and thus advance the traveler along the track until the traveler enters upon the outwardly-curved end of the track, thus separating the actuating arm and lug, substantially as described.

5. In a baling-press or the like, the combination with a continuously-rotatable cam-block and a fixed curved track disposed above said cam-block, of a depending traveler slidingly engaging said track, a power-transmitting connecting-rod swiveled to the under side of said traveler, said rod having a depending lug, a fixed arm projecting radially from the periphery of the cam-block and adapted to contact said lug to advance the traveler along the track, and means slidingly engaged by said connecting-rod adjacent its connection to the traveler and serving to prevent lateral distortion of the latter relatively to its track, substantially as described.

6. In a baling-press or the like, the combination with a continuously-rotatable cam-block and a fixed curved track disposed above said cam-block, of a depending traveler slidingly engaging said track, a power-transmitting connecting-rod swiveled to the under side of said traveler, said rod having a depending lug and a lateral protuberance at its swiveled end, a fixed arm projecting radially from the periphery of the cam-block and adapted to contact said lug to advance the traveler along the track, and a fixed curved guide-rail disposed parallel with the outer side of said track and closely adjacent thereto, said guide-rail being slidingly engaged on its lower face by the lateral protuberance of the connecting-rod to prevent lateral distortion of the traveler relatively to its track, substantially as described.

7. In a baling-press or the like, an elongated framework or casing adapted to connect the power-receiving devices with the rear end of the press-body and to contain the power-transmitting connections to the follower, said casing being formed in two longitudinal sections the proximate ends of which abut each other in a knuckle-joint, as and for the purpose described.

8. In a baling-press or the like, an elongated framework or casing adapted to connect the power-receiving devices with the rear end of the press-body, said casing being made in two endwise-abutting sections having a knuckle-joint at their point of abutment, and a transverse rod disposed across said casing adjacent the knuckle-joint and serving to sustain the power-transmitting connections above the bottom of the casing at said joint, substantially as and for the purpose described.

9. In a baling-press or the like, an elongated casing for the power-transmitting connections, said casing being formed in two unconnected longitudinal sections which abut each other in a knuckle-joint, the rear section being adapted to contain at its rear end the power-receiving devices and having at its forward end a transverse support for the power-transmitting connections, and the forward section adapted to form a knuckle-joint with a fixed abutting member on the press-body in the line of draft of the power-transmitting connections, substantially as and for the purpose described.

10. In a baling-press or the like, an elongated casing formed in two unconnected endwise-abutting sections, power-receiving devices mounted in the rear end of the rear section, a press-body having a fixed rearwardly-extending bracket adapted to abut the forward end of the front section of the casing, a pair of guide-pulleys mounted in said bracket, and power-transmitting connections connected with the power-receiving devices and passing through said sectional casing and thence around said guide-pulleys, the abutting ends of the sections of the casing and the bracket being provided with knuckle-joints within which the line of draft falls, substantially as and for the purpose described.

11. In a baling-press or the like, an elongated casing formed in two unconnected endwise-abutting sections, power-receiving devices having curved paths of movement mounted in the rear end of the rear section, a press-body having a fixed rearwardly-extending bracket adapted to abut the forward end of the front section of the casing, a pair of guide-pulleys mounted in said bracket, and power-transmitting connections between the power-receiving devices and the pulleys, the same comprising a pair of rods longitudinally disposed within the casing and chains connected with the ends of said rods, and operating over the curved paths of said power-receiving devices and the peripheries of said pulleys, substantially as and for the purpose described.

12. A baling-press chamber having a vertically-extensible top wall and a door at one end thereof, combined with a locking device normally serving to lock the top of the chamber against extension, and connections therefrom to the door whereby, when the door is opened, the locking device is released and the top is free to rise under the expansion of the bale, substantially as described.

13. A baling-press chamber having a stationary bottom and front wall and a vertically-extensible top wall and a door covering one end of the chamber, in combination with a locking-arm for the top wall and connections therefrom to the hinge of the door, said arm engaging the top wall in a manner to prevent movement thereof when the door is closed and to permit the rise thereof when the door is opened, substantially as described.

14. In a baling-press, the combination with a bale-chamber and a fixed horizontal frame surrounding and surmounting the same, of a top or cover for the chamber, a series of obliquely-disposed links whereby said cover is suspended from said frame, a door closing one entire end of the chamber, a locking-arm pivoted to said frame and in its locking position abutting said cover, and a link connecting said locking-arm with the hinge of the door, whereby the opening of the door withdraws said locking-arm and permits the cover to swing rearwardly and upwardly on its supporting-links, all substantially as described.

15. In a baling-press, the combination with a bale-chamber having stationary front and bottom walls and a pair of doors constituting the end walls of the chamber, respectively, of a top or cover for the chamber mounted so as to be capable of a vertical extension, a locking device for said top or cover, and an interchangeable connection between said locking device and either of said doors adapted to maintain the cover in its lowermost position when the doors are closed and permitted to rise when the doors are opened, substantially as described.

16. In a baling-press chamber, the combination with a bale-chamber and a fixed horizontal frame surrounding and surmounting the same, of a top or cover for the chamber, a series of obliquely-disposed links whereby said cover is suspended at its ends from said frame, doors closing the entire ends of the chamber, respectively, a horizontal locking-arm pivoted to said frame and at its free end abutting the vertical rear wall of said cover, and an interchangeable link adapted to connect said locking-arm with the hinge of either of said doors, whereby when that door to which the arm is connected is opened, the locking-arm is withdrawn and the cover is free to swing rearwardly and upwardly, substantially as described.

17. In a baling-press, the combination with a bale-chamber and a door hinged and covering one end of the same, of a locking-hasp pivoted to said door near the outer or free edge thereof, a fixed staple adapted to receive the outer end of the hasp when the door is closed, and means for locking the inner end of the hasp against outward movement relatively to the door, substantially as described.

18. In a baling-press, the combination with a bale-chamber and a hinged door covering the entire end thereof, of a locking-hasp having an inwardly-bent outer end pivoted just back of such inwardly-bent end to said door near the outer or free edge thereof, a fixed staple adapted to receive the inwardly-bent end of the hasp when the door is closed, and means on the door adapted to engage the longer rearwardly-extending arm of the hasp and thereby lock the door in closed position, substantially as described.

19. In a baling-press, the combination with a bale-chamber and a hinged door covering the entire end thereof, of a locking-hasp having inwardly-bent outer and inner ends and pivoted just back of its outer end to the door near the free or outer edge thereof, a fixed staple adapted to receive the inwardly-bent outer end of the hasp when the door is closed, and a pivoted staple mounted in the outer face of the door and adapted to override the inwardly-bent inner end of the hasp and thereby lock the door in closed position, substantially as described.

20. In a baling-press, the combination with a bale-chamber provided with suitable transverse slots in the containing-walls thereof, of a wire-tucking device, the same comprising an arm pivoted above said chamber and means for actuating the same, and a wire-clamp mounted on the free end of said arm and adapted to clamp the wire and force the same through the slotted walls of the chamber upon the actuation of said arm, substantially as described.

21. In a baling-press, the combination with a bale-chamber provided with suitable transverse slots in the containing-walls thereof, of a wire-tucking device, the same comprising an arm pivoted above said chamber and means for actuating the same, a wire-clamp mounted on the free end of said arm and adapted to clamp the wire and force the same through the slotted walls of the chamber during its downward movement, and a clamp-releasing device adapted to receive the clamp and automatically release the wire therefrom when the arm reaches the limit of its operative movement, substantially as described.

22. In a baling-press, the combination with a bale-chamber having transverse slots formed through the walls thereof to permit the admission of the baling-wires, of means for tucking the wires therethrough, the same comprising a horizontal rock-shaft mounted above and along one side of the chamber, a pair of arms one fixedly and the other loosely mounted adjacent each other and at corresponding ends upon said rock-shaft, means limiting the angle of divergence of said arms, and clamps on the outer free ends of said arms adapted to grip the baling-wires and successively force the same through the slotted walls of the chamber upon the actuation of the rock-shaft, substantially as described.

23. In a baling-press, the combination with a bale-chamber having transverse slots formed through the walls thereof to permit the admission of the baling-wires, of means for tucking the wires therethrough, the same comprising a horizontal rock-shaft mounted above and along one side of the chamber, a pair of arms one fixedly and the other loosely mounted adjacent each other and at corresponding ends upon said rock-shaft, a link embracing said arms near their pivotal point and limiting their angle of divergence, clamps on the outer free ends of said arms adapted to clamp the baling-wires and successively force the same through the slotted walls of the chamber, and a stationary clamp-releasing device adapted to engage said clamps in the lowermost position of the arms, substantially as described.

24. In a baling-press, the combination with a bale-chamber having its top, bottom and front walls transversely slotted for the passage therethrough of the baling-wires, of a follower constituting the rear wall of the chamber, the face of the follower being provided with vertical grooves disposed in the same vertical planes as the slots of the chamber, and mechanism mounted above the chamber adapted to grip the baling-wires and tuck them through the slotted walls of the chamber and the grooves of the follower, substantially as described.

25. In a baling-press, the combination with a bale-chamber having its top, bottom and front walls transversely slotted for the passage therethrough of the baling-wires, of a follower constituting the rear wall of the chamber, the face of the follower being provided with vertical grooves disposed in the same vertical planes as the slots of the chamber, said grooves of the follower communicating with the interior space of the chamber through contracted longitudinal openings, and mechanism mounted above the chamber adapted to grip the baling-wires and tuck them through the slotted top and bottom walls of the chamber and the vertical grooves of the follower, substantially as described.

26. In a device of the character described, the combination with a power mechanism of means for transmitting a pull or stretch to a point remote from the power comprising a plurality of strut-like supports constituting compression members arranged to abut each other and flexibly united by means of hollow or divided joints and a traveler-cable extending from the power mechanism substantially through the centers of said joints to the points of power application, whereby any substantial flexing moment of the cable upon the compression members is avoided when said members are arranged out of direct alinement with each other, substantially as described.

27. In a mechanism of the character described, the combination with a cam-block adapted to be continuously rotated and a fixed track disposed adjacent said cam-block and on the arc of a circle whose center is coincident with the pivotal axis of the cam-block, said track having one side thereof abruptly turned out of the arc of curvature of the track, of a traveler slidingly engaging said track, and a fixed projection on the cam-block adapted to advance the traveler along the concentric portion of the track and to drop the traveler on the outwardly-turned end of the track, substantially as described.

28. A baling-press chamber having an outwardly-opening end door, and further having one of its sides formed by an outwardly-movable wall, in combination with obliquely-disposed links whereby said wall is hinged to a stationary external support, and locking means for said wall connected with the end door, said means locking the wall against outward movement when the door is closed, and releasing said wall when the door is opened, substantially as described.

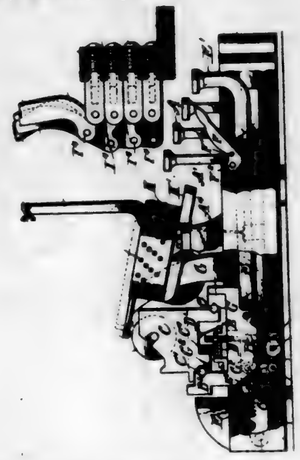
29. In a baling-press, a baling-chamber one side of which is constituted by an upwardly-movable wall or cover, in combination with means connected to said wall and to a stationary part of the press-frame, said means serving to counteract the weight of the wall and tending to raise the same out of contact with the underlying bale to facilitate the withdrawal of the latter, substantially as described.

30. In a baling-press, a baling-chamber one side of which is constituted by an upwardly-movable wall or cover, in combination with a spring connected to said wall and to a stationary part of the press-frame, said spring serving to counteract the weight of the wall and tending to raise the same out of contact with the underlying bale to facilitate the withdrawal of the latter, substantially as described.

31. In a baling-press, a baling-chamber one side of which is constituted by an upwardly-movable wall or cover, in combination with obliquely-disposed links whereby said movable wall is hinged to an external stationary support, means for locking said wall against upward movement, and a spring connected to said wall and to a stationary member of the press-frame and serving to counteract the weight of the wall and to raise the latter out of contact with the underlying bale when the locking means are withdrawn, substantially as described.

708,270. TYPE-WRITER TYPE-BAR AND SUPPORT. CHARLES SEIBU, New York, N. Y. Original application filed July 30, 1901. Serial No. 69,112. Divided and this application filed Oct. 24, 1901. Serial No. 79,256. (No model.)

Claim.—1. In a type-writer, a paper-carriage and platen, an arc-plate disposed with its upright concave face oblique to the horizontal and opposite said platen, and type-bar hangers mounted upon the concave face of said plate; substantially as specified.



2. An arc-plate for supporting type-bar hangers comprising a flange having upon its concave face a groove and an aperture extending from the convex face of said plate and intersecting said groove; substantially as specified.

3. In a type-writer, an arc-plate provided with a longitudinal groove upon its concave face and a series of apertures extending from said groove to the opposite face, a hanger having a flange adapted to enter said groove, a securing device passing through the aperture in said plate and entering said hanger, and a type-bar mounted in said hanger; substantially as specified.

4. In a type-writer, an arc-plate having parallel longitudinal grooves upon one face, and a series of hangers mounted thereon in different horizontal planes and with their vertical centers in different vertical planes; substantially as specified.

5. In a type-writer, a carriage and platen, a segmental plate disposed with its upright concave face oblique to the horizontal and opposite said platen, and a series of type-bars and hangers staggered or stepped upon the concave surface of said plate next to said platen; substantially as specified.

6. A type-bar hanger comprising a block having a threaded transverse aperture therein, pivoting-ears at opposite ends, and a securing-flange extending longitudinally across the back of said hanger in alinement with said aperture; substantially as specified.

7. A type-bar comprising a plate having the body thereof at one end slitted and pressed in opposite directions to form an eye to receive a type-shank; substantially as specified.

8. A type-bar comprising a plate having the body thereof at one end slitted and pressed in opposite directions to form an eye to receive a type-shank and provided at its opposite end with an extended portion having a pivoting-aperture and connecting-eye for a ligament; substantially as specified.

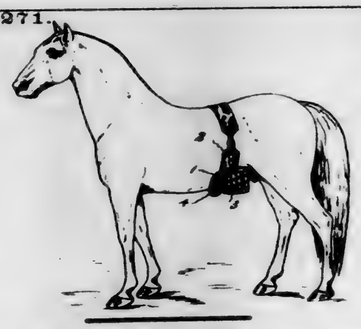
9. A type-bar comprising a plate having the body thereof at one end slitted and pressed in opposite directions to form an eye to receive a type-shank and provided at its opposite end with an extension below the body of the plate and having a pivoting-eye beyond said extension and a ligament-eye below said pivoting-eye; substantially as specified.

10. A type-bar comprising a plate having the body thereof at one end slitted and pressed in opposite directions to form an eye adapted to receive a type-shank and at its opposite end provided with an extension in the plane of the bar extending at an angle thereto and provided with a ligament-eye, and a body portion having a pivoting-eye beyond said extension; substantially as specified.

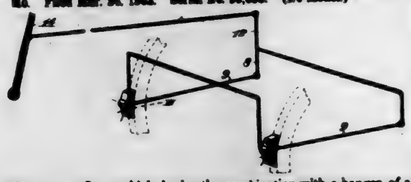
708,271. VETERINARY APPLIANCE. NEIL STALKER, West Hartford, Conn. Filed Nov. 20, 1901. Serial No. 83,094. (No model.)

Claim.—A veterinary appliance consisting of a shield, straps for attaching the shield to a horse, a pocket hanging from the shield, an alarm-ball depending from the under side of the shield near the front of the pocket, and a disk located in the front of the pocket and connected with the ball, substantially as specified.

708,271.



708,272. VEHICLE-BRAKE. JONAS A. TAUTPHAUS, Sappington, Mo. Filed Mar. 24, 1902. Serial No. 99,055. (No model.)



Claim.—1. In a vehicle-brake, the combination with a hanger, of a pull-rod loosely connected to the hanger, and a brake-head loosely pivoted to the hanger, of an eyebolt seated in the brake-head and in which the pull-rod is positioned to provide a connection between pull-rod and brake-head independently of the hanger.

2. In a vehicle-brake, the combination with a swinging hanger, suspended from the wagon-body, formed of a continuous piece of material, and comprising a horizontal portion, a depending portion at each end of the horizontal portion, and outturned ends; of brake-heads carried by the outturned ends of the hanger, a rock-shaft carried by the running-gear, pull-rods secured to the outturned ends of the hanger between the brake-heads and the depending portion, and connecting with the rock-shaft, eyebolts secured in the brake-heads and receiving the pull-rods, and means for operating the rock-shaft.

708,273. SAW. JOSEPH TUTTEROW, Morgantown, Ind. Filed Apr. 23, 1902. Serial No. 104,364. (No model.)

Claim.—1. A crescent-saw blade-smith thicker near the cutting edge than at the back, and having a central pair of planer-teeth with perpendicular faces set in opposite directions and a notch between said teeth, the edge curving from said central teeth toward each end of the blade, and having teeth arranged in groups of three with recesses between the groups, said recesses each approximating the width of a group of three teeth, and each group having two cutter-teeth and one clearer-teeth.

2. A crescent-saw blade with plane sides, the curved edge much thicker than the back, having a central pair of clearing-teeth with perpendicular faces in opposite directions, and teeth arranged in groups of three between said clearing-teeth and the ends of the saw, spaces between the groups of teeth, each space approximating the width of a group of three teeth, each group of three consisting of two cutters beveled on opposite sides and a planer-tooth at the side of the group toward the end of the saw, the planer-teeth having their planer-faces substantially perpendicular to the back of the saw.

708,274. CAR-COUPLING. JOHN R. WADE, Brooklyn, N. Y. Filed Jan. 10, 1900. Serial No. 971. (No model.)

Claim.—1. In a car-coupling, a draw-head, a knuckle pivoted therein and a movable locking-piece adapted to engage said knuckle and a transient member whereby said coupling is locked.

2. In a car-coupling, a draw-head, a knuckle pivoted therein, comprising an engaging jaw and a locking-arm at approximately right angles thereto and a vertically-movable locking-piece adapted to be raised by said arm and to engage said arm and a transient member whereby said coupling is locked.

3. In a car-coupling, a draw-head, a knuckle pivoted therein, comprising an engaging jaw and a locking-arm at approximately right angles thereto, and a vertically-movable swinging locking-piece adapted to be raised by said arm and to engage said arm and a transient member whereby the coupler is locked and also adapted upon withdrawal of said transient member to swing outwardly, whereby said knuckle is permitted to assume the open position.

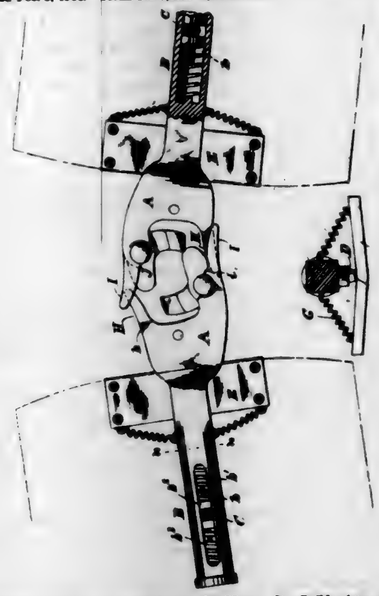
4. In a car-coupler, a draw-head, a knuckle pivoted therein, comprising an engaging jaw and a locking-arm at approximately right angles thereto, a vertically-movable swinging locking-piece adapted to be raised by said arm and to engage said arm and a transient member whereby the coupler is locked and also adapted upon the withdrawal of said transient member to swing outwardly whereby said knuckle is permitted to assume the open position and respective means whereby the oscillation in each direction of said locking-piece is limited.

5. In a car-coupling, a draw-head, a knuckle pivoted therein comprising an engaging jaw and a locking-arm at approximately right angles thereto, an inclined bearing therefor whereby it normally assumes the open position, a vertically-movable swinging locking piece adapted to be raised by said arm and to engage said arm and a transient member whereby said coupler is locked and also adapted upon the withdrawal of said transient member to swing outwardly whereby said knuckle is permitted to assume the open position and respective means whereby the oscillation in each direction of said locking-piece is limited.

6. In a car-coupling, a draw-head, a knuckle pivoted therein comprising an engaging jaw and a locking-arm at approximately right angles thereto an inclined bearing therefor whereby it normally assumes the open position, a stop G and an incline H in said draw-head and a vertically-movable swinging locking-piece pivoted between said stop and said incline and adapted to be raised by said arm and to engage said arm and a transient member whereby said coupling is locked.

7. In a car-coupling, a draw-head, a knuckle pivoted therein comprising an engaging jaw and a wedge-like locking-arm at approximately right angles thereto, an inclined bearing therefor whereby it normally assumes the open position, a stop G and an incline H in said draw-head and a vertically-movable swinging locking-piece pivoted between said stop and said incline and adapted to be raised by said locking-arm and to engage said arm and a transient member whereby said coupling is locked.

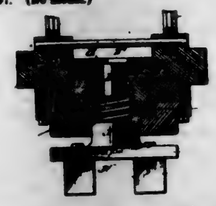
708,275. CAR-COUPLING. JOHN R. WADE, Brooklyn, N. Y. Filed Feb. 3, 1900. Serial No. 3,910. (No model.)



Claim.—1. In a car-coupler of the Master Car-Builders' type, a draw-head provided with diagonally opposite approximately vertical guide-surfaces A A and forwardly-extended laterally-flared horns above and below said surfaces respectively adapted to engage similar guide-surfaces on an opposing coupler-head whereby said coupler-heads are brought substantially into alinement, substantially as described.

2. The combination with a coupler pivoted at its shank, of a centrally-inclined supporting-slideway, a friction-ball between the coupler and slideway, and an auxiliary tensional centering-support.

708,276. PLUNGER-ADJUSTING MECHANISM FOR RE-PRESS BRICK MACHINES. JOSEPH WALKER, St. Elmo, Va., assignor of one-half to Henry P. West, Washington, D. C. Filed Mar. 24, 1902. Serial No. 99,697. (No model.)



Claim.—The combination with a reciprocating cross-head having an upper bored casing, of a plunger, having a smooth upper portion fashioned into said bore and capable of vertical movement therein, said plunger having a screw-threaded middle body, an enlarged smooth lower body adapted to move freely in bore of the lower casing, secured by means of bolts to the cross-head, said lower casing having a slot in its front face allowing an adjusting-handle to work therethrough, said handle being secured in contact of a nut working upon threads of plunger, said nut being clamped between the upper and lower casings, substantially as shown and described.

708,277. TELEPHONE OR TELEGRAPH POLE. ISAAC M. WARNER, Union City, Mich., assignor to Frank C. Boise, Union City, Mich. Filed Oct. 18, 1901. Serial No. 78,730. (No model.)

Claim.—1. The combination of a tubular pole, a bolt projecting vertically from the upper end thereof and having its lower end secured therein, a cross-arm provided with a series of wire-supports on said bolt, bearing on the upper end of said pole and means, independent of said bolt to secure said cross-arm to said pole, substantially as described.

2. The combination of a tubular pole, a bolt projecting vertically from the upper end thereof and having its lower end secured therein, cross-arms on said bolt, a space-block on said bolt between said cross-arms, the lowermost cross-arm bearing on the upper end of the pole, and a clamping-nut on said bolt bearing on the upper cross-arm, substantially as described.

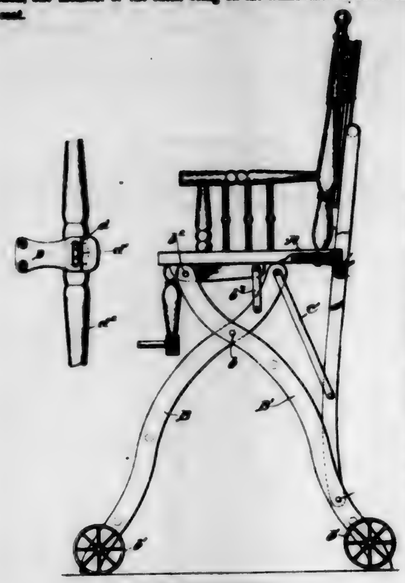
3. The combination of a tubular pole, a bolt 10 having its lower end inserted in the upper end of the tubular pole, a bolt passed transversely through the upper portion of the pole and the lower portion of said bolt 10 to secure the latter in the pole and a cross-arm secured on the projecting upper portion of said bolt 10 and bearing on the upper end of the pole, substantially as described.

708,278. CONVERTIBLE CHAIR. THEODORE W. WARNEKE, Baldwinsville, Mass., assignor to Gilman Waite, Baldwinsville, Mass., doing business as the Waite Chair Company. Filed Sept. 13, 1900. Serial No. 780,209. (No model.)

Claim.—1. In a convertible chair the combination of crossed legs pivoted together; a seat pivoted to the rear legs and connected by a link to the front legs; and a frame pivoted to the rear legs and connected by a link to the front legs.

2. In a convertible chair the combination of crossed legs pivoted together; a seat pivoted to the rear legs and connected by a link to the front legs; a frame pivoted to the rear legs and connected by a link to the front legs; and a spring-catch for holding the chair in its elevated

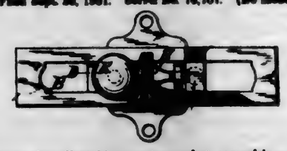
position, one member of the catch being on the frame and the other on the seat.



708,279. SELF-IGNITER. SARAH WATERMAN, New York, N. Y. Filed Feb. 6, 1902. Serial No. 92,775. (No model.)

Claim.—A self-igniter composed of a bail, platinum wires depending from the bail ends, a number of spaced igniting-pellets carried by the platinum wires, and platinum spirals that encircle the wires intermediate the pellets and extend from pellet to pellet, substantially as specified.

708,280. ADJUSTABLE CURTAIN-BRACKET. LOUIS A. WATTS, Cincinnati, Ohio, assignor of one-half to George Schott, Cincinnati, Ohio. Filed Sept. 30, 1901. Serial No. 76,707. (No model.)



Claim.—1. An adjustable curtain-bracket comprising a base-plate adapted to be secured to a window-frame or support, said base-plate being longitudinally grooved at its under side and having its face longitudinally slotted, a slide fitted in said grooved base-plate having an integral sleeve projecting through said slotted face at right angles, a set-screw locking said sleeve in position, an arm slidably fitted in said sleeve having a head formed to support a roller-spindle, and a set-screw locking said arm in position; substantially as described.

2. An adjustable curtain-bracket comprising a base-plate adapted for attachment to a support, said plate being longitudinally grooved at its under side and having its face longitudinally slotted, an angle-shaped member having one arm slidably fitted in said grooved base-plate and its other arm extending through the slotted face thereof, said latter arm being in the form of a sleeve and of proper external size to permit insertion or detachment of the member from the under side of the base-plate, a set-screw screwed into the upper part of the slide-arm of said member having a flat base engaging the face of the base-plate, and a roller-supporting member adjustably secured in the sleeve-arm of said member, substantially as described.

708,281. ADJUSTABLE SHADE-BRACKET. LOUIS A. WATTS, Cincinnati, Ohio, assignor of one-half to George Schott, Cincinnati, Ohio. Filed Feb. 10, 1902. Serial No. 93,362. (No model.)

Claim.—1. An adjustable shade-bracket comprising an arm adapted for direct attachment to the inner side of a window-frame to project laterally, and a roller-supporting arm secured thereon, adjustable lengthwise thereof and extending substantially at right angles therefrom, substantially as described.

2. An adjustable shade-bracket comprising an arm adapted for attachment to the inner side of a window-frame to project laterally therefrom, and a roller-holding member supported thereby, one of said members having a sleeve fitting on the other in slidable relation, screw-holes in opposite sides of said sleeve, and a set-screw insertible in either of said screw-holes for locking the roller-holding member in position; substantially as described.

3. An adjustable shade-bracket comprising an arm adapted for attachment to the inner side of a window-frame to project laterally therefrom, a roller-holding member consisting of a sleeve having an arm extending at right angles therefrom and formed to receive a roller-spindle, the said sleeve being fitted on said first-mentioned arm, and a set-screw for locking the roller-holding member in position; substantially as described.

4. An adjustable shade-bracket comprising two right-angle members having corresponding arms parallel and adjustably secured together, the free arm of one member being formed to receive a roller-spindle, and the corresponding arm of the other member constituting a base-plate for attachment to the inner side of a window-frame, substantially as described.

5. An adjustable shade-bracket comprising two right-angle members having corresponding arms adjustably fitted lengthwise together and their free arms extending therefrom in the same direction, one of said free arms being formed to receive a roller-spindle and the other being adapted for attachment to a support; substantially as described.

6. An adjustable shade-bracket comprising an angle-shaped bracket member, one of the arms of which is adapted for attachment to a support, a similarly-shaped roller-holding member having its corresponding arm formed to receive a roller-spindle, the other arm of the latter member being in the form of a sleeve and slidably embracing the corresponding arm of the bracket member, and a set-screw for locking the roller-holding member in place; substantially as described.

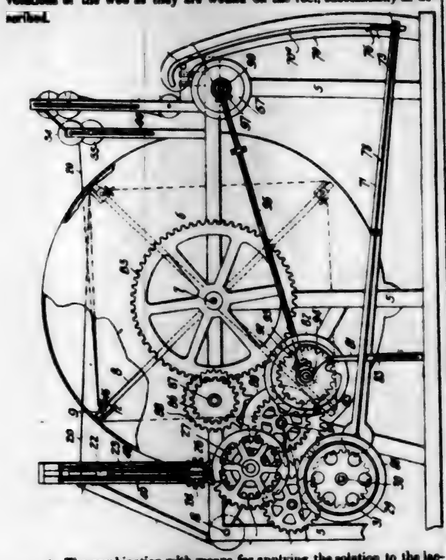
7. An adjustable shade-bracket comprising an angle-shaped bracket member, one arm of which is adapted for attachment to a support, and a similarly-shaped roller-holding member arranged with its arms extending in the same directions and having its corresponding arm formed to receive a roller-spindle, the remaining arms of said members being secured together in adjustable relation, one being in the form of a sleeve and the other slidably fitted therein, and a set-screw for locking the roller-holding member in place; substantially as described.

708,282. SHOE-LACING-TIP MACHINE. CHARLES D. WEAVER, McPherson, Kans., assignor to the Clark-Weaver Manufacturing Company, Crosley, Colo. Filed Aug. 16, 1901. Serial No. 72,304. (No model.)

Claim.—1. In a machine for applying non-metallic tips to shoelaces, the combination with a framework, of a supply-spool, solution-applying mechanism, a reel for drawing the lacing-web from the supply-spool, means mounted on the reel for keeping the convolutions of the web separated and to prevent them from winding on top of one another, molding devices to which the web passes after leaving the reel, a cutting device for severing the lace from the web, and means for drawing the lacing-web from the reel to a position to be acted on by the cutting device.

2. In a machine of the class described, the combination with means for applying the solution to the lacing-web, of a drying-reel upon which the web is wound after the solution is applied, means, mounted on the reel for automatically shifting the convolutions, whereby a convolution wound in one plane is moved out of the way to allow the next convolution to wind in the same plane, and so on, the arrangement being such that any desired number of convolutions may be constantly maintained on the reel, between the plane where the web is received and the plane where it passes from the reel, whereby any convolution is held in the drum a sufficient length of time for partially drying the applied solution.

3. The combination with means for applying the solution to the lacing-web, of a stationary drum or casing, a drying-reel actuated by said casing, and means mounted on the reel for automatically shifting the convolutions of the web as they are wound on the reel, substantially as described.



4. The combination with means for applying the solution to the lacing-web, of a drying-reel and chains mounted on the reel-arms for automatically shifting the convolutions of the web in a direction parallel with the axis of the reel, for the purpose set forth.

5. In a machine of the class described, the combination with a suitable supporting-frame, of a trough for holding the solution, said trough being mounted to move vertically on the frame, spring-supported gates normally closing openings in the sides of the trough, other gates in alinement with the trough-gates, and means for raising the trough to immerse the lacing-web in the solution therein, the arrangement being such that the upper gates displace the trough-gates and prevent the escape of the solution when the trough-gates are lowered for the purpose stated.

6. In a machine of the class described, the combination of a solution-containing trough, movable gates normally closing web-openings in the opposite sides of the trough, vertically-movable gates located above and in alinement with the trough-gates, and means for simultaneously raising the trough and lowering the upper gates to immerse the lacing-web in the solution, the arrangement being such that the two sets of gates meet on the web, the trough-gates being displaced by the other gates to allow the immersion of the web in the solution and prevent the escape of the solution from the trough, the meeting edges of the gates being provided with yielding material as rubber for the purpose set forth.

7. In a machine of the class described, the combination with a suitable framework, of a solution-containing trough mounted to move vertically in the framework, a cover for said trough, means for supporting the lacing-web out of the plane of the trough, and means for raising and lowering the trough to bring it in a position to immerse a portion of the web in the solution, and means for automatically actuating the cover during the trough's vertical movement, substantially as described.

8. In a machine of the class described, the combination with a suitable framework, of a solution-containing trough mounted to move vertically therein, means for supporting the lacing-web above the plane of the trough, a movable cover normally closing an opening in the top of the trough, and means for automatically actuating said cover to open the trough to allow the immersion of the lacing-web as the trough is raised for the purpose set forth.

9. In a machine of the class described, the combination with a suitable framework, of a solution-containing trough mounted to move vertically in the framework, spring-supported gates normally closing openings in the sides of the trough, and gates mounted above the trough-gates and arranged to meet and displace the latter to allow the immersion of the web in the solution, means for simultaneously raising the trough and lowering the upper gates for the purpose, a movable cover for the trough, and a slide located below the upper gates when the mechanism is at rest, and means for automatically actuating the cover and slide as the trough is raised for the purpose set forth.

10. In a machine of the class described, the combination with means for applying solution to the lacing-web, of a drying-reel upon which the web is wound after the solution is applied, molding devices to which the web is passed after leaving the reel, a stationary block, means for drawing the web from the reel, through the molding devices and across said block, and a reciprocating cutter device arranged to sever the web where it engages the block, so as to leave a portion of the web to which the solution is applied, on each side of the cutter.

11. In a machine of the class described, the combination with a series of web-supply spools, of a reel for drawing the web from the supply-spools, means intermediate the spools and the reel for simultaneously applying solution to all the webs, molding devices to which the series of webs pass after leaving the reel, stationary blocks, means for drawing the webs across said blocks in such a manner that the portion of each web to which the solution is applied, shall engage the blocks, and a reciprocating rod provided with cutters adapted to sever the webs where they engage the blocks, the arrangement being such that the solution-applying mechanism and the cutters act simultaneously while the reel is at rest, these devices in turn being at rest while the reel is in operation.

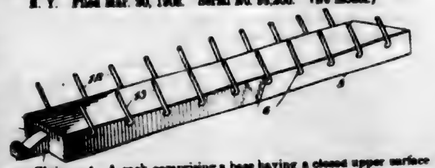
12. In a lacing-tip machine, the combination with spools adapted to hold a series of lacing-webs, of means for simultaneously applying solution to a portion of all the webs, an intermittently-operated reel for drawing the webs from the spools, molding devices through which the webs pass after leaving the reel, stationary blocks, means for drawing the webs across the stationary blocks, a reciprocating rod provided with projections adapted to engage the webs and to hold them in place on the blocks, and a reciprocating rod provided with cutters adapted to sever the webs at the blocks.

13. In a machine of the class described, the combination with supply-spools upon which the lacing-webs are wound, of solution-applying mechanism for all the webs, a reel upon which the webs are wound, molding devices through which the webs pass after leaving the reel, cutting devices acting on the webs after they leave the molding devices, and means for drawing the webs from the reel, through the molding devices, and into position to be acted on by the cutters, said means comprising oscillating arms and two rods connected with said arms and provided with codperating fingers, one of the said rods being movable endwise, levers mounted on the oscillating arms and connected with the movable finger-rod to operate the latter, the arrangement being such that the fingers of the rods are raised and grasp the lacing-webs in proximity to the cutters and then descend while holding the webs, whereby the aforesaid function is performed.

14. In a machine of the class described, the combination with supply-spools, means for applying solution to a portion of the webs, a reel for drawing the webs from the spools, molding devices, cutting devices, and means for drawing the webs after they leave the reel, through the molding devices and into position to be acted on by the cutting devices, said means comprising a pair of oscillating arms, a rod journaled in said arms, a second rod rigidly attached to the first-named rod, extending parallel therewith, and separated therefrom, upwardly-projecting stationary arms having slots in which the two rods move as the oscillating arms are raised, fingers fast on the two rods, the direction of the slots in the upper extremities of the stationary arms, being changed to cause the first-named rod to turn in the bearings of the oscillating arms, whereby the fingers of the rods are projected to one side of the stationary webs, a third rod mounted to have an endwise movement on the first-named rod, provided with fingers connected to slide on the second rod, and levers mounted on the oscillating arms and connected with the third rod for imparting the endwise movement thereto, whereby the webs are grasped between the two sets of fingers, and as the oscillating arms descend the webs are drawn downwardly for the purpose set forth.

15. The combination with means for applying the solution to the lacing-web, of a drying-reel and chains mounted on the reel-arms for automatically shifting the convolutions of the web in the direction parallel with the axis of the reel and a support between the reel-arms to prevent the chain from sagging.

708,288. POSTMAN'S RACK. CHARLES J. WEBER, Tarrytown, N. Y. Filed Mar. 20, 1902. Serial No. 99,205. (No model.)



Claim.—1. A rack comprising a base having a closed upper surface to support letters of different lengths, said base having an opening in one

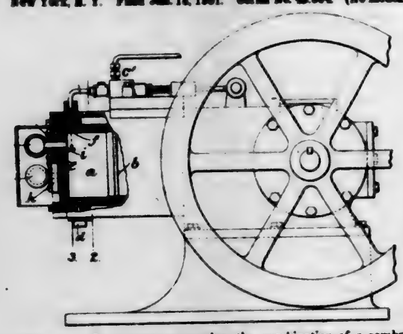
end, a plurality of U-shaped wires having their bight portions journaled in the sides of the base for movement of their end portions above and below the upper surface of the base said bight portions being centrally offset, a single shift-rod pivoted to the bight portions and projecting at one end through the opening in the end of the base, and a spring connected with the opposite end of the shift-rod and to the adjacent end of the base to hold the rod yieldably at one limit of its movement with the ends of the U-shaped wires in lowered positions, the projecting end of the shift-rod having a notch to receive the end of the base to hold the rod against the action of the spring.

2. A postman's rack comprising a base having a continuous upper surface, and having an opening at one end, arms pivotally mounted in the sides of the base for movement into position above and below the upper surface of the base, a shift-rod mounted in the base and operatively connected with the arms for shifting them and a spring connected to one end of the shift-rod and to the base for holding the rod with the arms lowered, the opposite end of the shift-rod projecting from the base and adapted for engagement with the base to hold the rod against the action of the spring.

3. A rack comprising a base, a plurality of U-shaped wires having their bight portions journaled in the base and having central offset supplemental bight portions, a shift-rod pivotally connected with the supplemental bight portions, a spring connected with the shift-rod for holding it yieldably at one limit of its motion, and a latch-tongue connected with the opposite end of the rod and adapted for engagement with the base to hold the rod against the tendency of the spring.

4. A rack comprising a hollow base having a continuous upper surface, a plurality of separating devices connected in pairs and journaled in the sides of the base for movement into erect and reclining positions above and below the upper surface of the base respectively, a shift-rod within the base connecting the separating devices for actuating them, and yieldable means within the base and connected with the rod for holding it yieldably with the separating devices in erect positions, said rod projecting at one end from the base and constructed to engage the base to hold the rod against the action of the yieldable holding means.

708,284. INCANDESCENT IGNITER FOR EXPLOSIVE-ENGINES. CARL W. WEISS, New York, N. Y., assignor of one-half to August Mietz, New York, N. Y. Filed Jan. 14, 1901. Serial No. 43,004. (No model.)

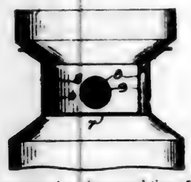


Claim.—1. In an explosive-engine, the combination of a combustion chamber or cylinder, a plurality of separate and independent igniters disposed on the cylinder-head at widely-separated points to ignite the charge at different places in the combustion-chamber simultaneously, one or more of said igniters having a projection within the cylinder, and means to inject the fuel against such projection, substantially as described.

2. In an explosive-engine, the combination of a single combustion-chamber, a fuel-supply pipe having a nozzle with a plurality of inlet-openings, a plurality of separate and independent igniters disposed on the cylinder-head at widely-separated points within said single chamber to ignite the charge at different places in said chamber simultaneously, the igniters in line with said inlet-openings being provided with lips to receive and vaporize the fuel, substantially as described.

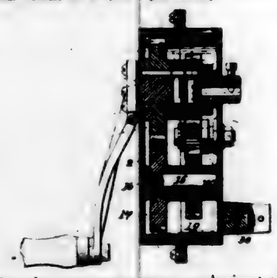
708,285. COMBINED MILK STRAINER AND VENTILATOR. PAUL WEISS, Lester Prairie, Minn. Filed Sept. 26, 1901. Serial No. 76,608. (No model.)

Claim.—1. The combination with a milk-can having a flaring mouth, of a milk-can cover and strainer, consisting of a flaring ring, a cylindrical part supported from said flaring ring and provided with an imperforate bottom and having openings in its side walls above the imperforate bottom, and screen-coverings to the openings in the side walls, said screen-openings being arranged so that when the cover is in one position they will lie opposite to the walls of the neck of the can and when the cover is reversed they will be above the flaring mouth of the can and below the inverted imperforate bottom, and said flaring ring being so located that in one position it will rest on the flaring mouth portion of the can, substantially as described.



2. A milk-can cover and strainer, consisting of a ring with straight walls, a cylindrical part with an imperforate bottom and having openings in its side walls above the imperforate bottom, screen-coverings to said openings, and a flaring ring connecting said straight-walled ring and cylindrical part, said straight-walled ring projecting from the flaring ring so as to constitute an upright wall extending above the same when the device is serving as a strainer, and to constitute a depending outer wall overhanging the mouth of the can when the device is serving as a cover, and in connection with the flaring ring serving to shed rain from the cover and away from the mouth of the can, substantially as described.

708,286. POWER-TRANSMITTING DEVICE FOR HAND-DRIVEN MECHANISMS. FREDERICK W. WILD, Jr., Baltimore, Md. Filed May 6, 1902. Serial No. 106,115. (No model.)

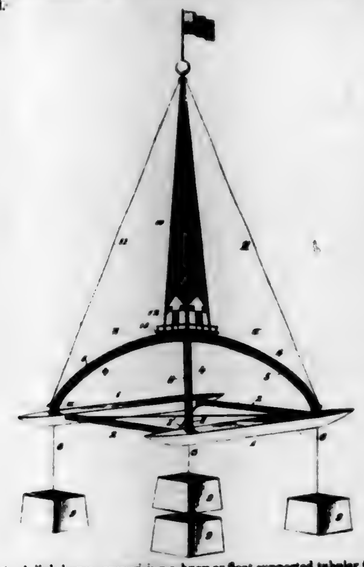


Claim.—In a power-transmitting mechanism for the purpose described, a spindle which has to be rotated in a certain direction, a gear-wheel loose on the said spindle and to which power is applied, a ratchet mechanism constructed to transmit rotary movement from the said gear-wheel to the spindle when the said gear-wheel is rotated in one direction only, or that to be taken by the spindle, a second gear-wheel loose on the said spindle with ratchet mechanism which in effect is the same as the first, combined with a train of gearing driven from the first gear-wheel, whereby in the reversal in direction of the first gear-wheel, the second gear-wheel is caused to rotate in an opposite direction to that of the first, thereby continuing the rotation of the spindle in the first-described and required direction, substantially as specified.

708,287. FLOATING LIGHTHOUSE. JOHN C. WILLIAMS, Kansas City, Mo. Filed Oct. 24, 1901. Serial No. 79,902. (No model.)

Claim.—1. The combination of a buoy or float supported lighthouse, embracing buoys or floats, intersecting arches connecting the same, suitable braces for the buoys or floats and arches, an upwardly-tapering tower centrally surmounting the arched frame, and braces connecting said arches near their ends with said tower, weights or anchors, cables extending up from the same to the lower ends of the arches, pulleys guiding said cables to the base of the tower, and means located therein for taking up or paying out said cables, substantially as described.

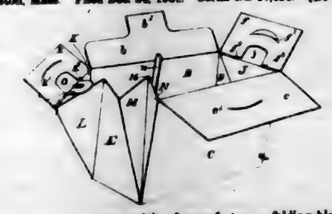
2. The combination of a plurality of buoys or floats provided with vertical passages or wells, braces connecting said buoys or floats, intersecting arches connecting said floats or buoys and the ends of said braces, said arches being of tubular construction, guide-pulleys arranged in said arches and at the lower ends of said wells or passages, a hollow tower centrally surmounting the arches, and suitably braced, a globe or lamp surmounting the tower, a house formed at the base of the tower and containing winding-drums, cables attached to said winding-drums and extending over said pulleys and down through said wells or passages, weights or anchors attached to the lower ends of said cables, means to turn said drums in one direction so as to wind up the cables, and means for preventing the accidental back rotation of the drums, substantially as described.



3. A lighthouse, comprising a buoy or float supported tubular frame, a tower mounted on said frame, and provided with a living-room, ladder suitably guided through said tubular frame, and into said room, weights resting on the bottom of the can, and attached to the lower ends of said cables, and means for winding up or paying out said cables in said room so as to accommodate the falling or rising of the water.

4. A lighthouse comprising a buoy or float supported structure provided with vertical passages or wells at suitable points, intersecting tubular arches registering at their lower ends with said wells or passages, and suitably braced, a skeleton tower surmounting the arches and provided with a living-room, cables connecting the upper part of the tower with the lower ends of the arches, cables suitably guided through said tubular arches and said wells or passages, weights attached to the lower ends of said cables, and means within said room for shortening or lengthening said cables, substantially as described.

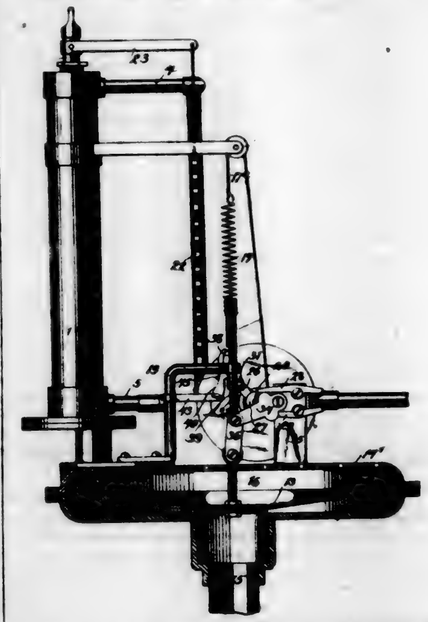
708,288. FOLDING BLANK PAPER BOX. DIOR L. WIBLOW, Boston, Mass. Filed Dec. 26, 1901. Serial No. 87,051. (No model.)



Claim.—1. As a new article of manufacture, a folding blank paper box consisting of a single sheet, comprising a bottom portion, front and rear side portions, and end portions, the said sides and ends being connected by folding portions, the two correspondingly-placed folding portions upon opposite sides of each of the said end portions and immediately next to the said side portions being provided one with a locking-tab and the other with a flap, the said flap of the folding portion having a plurality of slits, and the said locking-tab adapted to be passed through all the said slits during the folding operation thereby locking the folding portions together, substantially as described.

2. As a new article of manufacture, a folding blank paper box consisting of a single sheet, comprising a bottom portion, front and rear side portions, and end portions, the two correspondingly-placed folding portions upon opposite sides of each of the said end portions and immediately next to the said side portions being provided one with a locking-tab and the other with a flap, the said flap of the said folding portion having a plurality of slits and a tab formed by cutting through the said flap, the said tab formed in the flap being bent over an adjacent folding portion, and the said locking-tab adapted to be passed over the said bent flap-tab and through all the slits in the said flap during the folding operation thereby locking the folding portions together, substantially as described.

708,289. REGULATOR. HENRY R. P. WEBER, New York, N. Y. Filed Aug. 10, 1901. Serial No. 71,049. (No model.)



Claim.—1. In an apparatus for operating dampers in furnace-off takes, the combination, with a motor for moving such dampers and a motor controller, of an actuating device for operating said motor-controller, a primary controlling device operated by variations in pressure in the combustion-chamber, means operated by said primary controlling device controlling the operation of said actuating device, which actuating device derives its power from a source independent of the primary controlling device, and a compensating device for compensating for the difference in range between these variations in pressure which operate the apparatus to close the damper and these variations in pressure which operate to open the damper.

2. In an apparatus for operating dampers in furnace-offtakes, the combination, with a fluid-pressure motor for moving such dampers, and a controlling-valve for such motor, of an actuating device for operating said valve, a primary controlling device operated by variations in pressure in the combustion-chamber, means operated by said primary controlling device controlling the operation of said actuating device, which actuating device derives its power from a source independent of the primary controlling device, and a compensating device for compensating for the difference in range between these variations in pressure which operate the apparatus to close the damper and these variations which operate to open the damper.

3. In an apparatus for operating dampers in furnace-offtakes, the combination, with a motor for moving such dampers, and a motor-controller, of an energy-storing actuating device arranged to operate said motor-controller when released, means operated by the motor for storing up energy in said actuating device, a primary controlling device operated by variations in pressure in the combustion-chamber, means operated by the said primary controlling device, adapted to release the actuating device, and a compensating device, for compensating for the difference in range between the variations in pressure which operate the apparatus to close the damper and these variations which operate to open the damper.

4. In an apparatus for operating dampers in furnace-offtakes, the combination, with a motor for moving such dampers and a motor-controller, of a primary controlling device operated by variations in pressure in the combustion-chamber, an actuating device for operating the motor-controller, mechanically connected with and controlled by said primary controlling device, but deriving its power from an independent source, and a compensating device for compensating for the difference in range between the variations in pressure which operate the apparatus to close the damper and those variations which operate to open the damper.

5. In an apparatus for operating dampers in furnace-offtakes, the combination, with a motor for moving such dampers and a motor-controller, of a primary controlling device operated by variations in pressure in the combustion-chamber, an energy-storing actuating device for operating the motor-controller, mechanically connected with and controlled by said primary controlling device, but deriving its power from an independent source, and a compensating device for compensating for the difference in range between the variations in pressure which operate the apparatus to close the damper and those variations which operate to open the damper.

6. In an apparatus for operating dampers in furnace-offtakes, the combination, with a motor for moving such dampers and a motor-controller, of a primary controlling device operated by variations in pressure in the combustion-chamber, an energy-storing actuating device for operating the motor-controller, in which power is stored for such purpose by the motor in its operation, and which is mechanically connected with and controlled by said primary controlling device, and a compensating device for compensating for the difference in range between the variations in pressure which operate the apparatus to close the damper and those variations which operate to open the damper.

7. In an apparatus for operating dampers in furnace-offtakes, the combination, with a motor for moving such dampers and a motor-controller, of a primary controlling device operated by variations in pressure in the combustion-chamber, an energy-storing actuating device for operating the motor-controller, comprising a power-storing device, means operated by the motor in its operation for storing power therein, and a tripping mechanism for releasing said power-storing device, such tripping mechanism being arranged to be operated by the primary controlling device; and a compensating device for compensating for the difference in range between the variations in pressure which operate the apparatus to close the dampers and those variations which operate to open the dampers.

8. In an apparatus for operating dampers in furnace-offtakes, the combination, with a motor, a motor-controller, an energy-storing actuating device for operating the motor-controller, adapted to be released by a suitable tripping device, and means for storing up energy in said actuating device, of a primary controlling device adapted to be operated by change of conditions within the furnace and to release said actuating device, and provided with an automatically-operated locking device which prevents changes of conditions within the furnace from causing the operation of said controlling device, when once the actuating device has been released by said controlling device, until sufficient energy has been stored in said actuating device to again operate the motor-controller.

9. In an apparatus for operating dampers in furnace-offtakes, the combination, with a motor, a motor-controller, an energy-storing actuating device for operating the motor-controller, adapted to be released by a suitable tripping device, and means for storing up energy in said actuating device, of a primary controlling device adapted to be operated by change of conditions within the furnace and to release said actuating device, provided with an automatically-operated locking device which prevents changes of conditions within the furnace from causing the operation of said controlling device, when once the actuating device has been released by said controlling device, until sufficient energy has been stored in said actuating device to again operate the motor-controller, and a compensating device for compensating for the difference in range between the variations in pressure which operate the apparatus to close the damper and those variations which operate to open the damper.

10. The combination, with a motor, a motor-controller, an energy-storing actuating device for operating the motor-controller, adapted to be released by a suitable controlling device, and means for storing up energy in said actuating device, of a controlling device provided with a lock for preventing its operation at intervals, said controlling device being adapted to release said actuating device, and means for operating the lock so as to prevent the operation of said controlling device while energy is being stored in the actuating device.

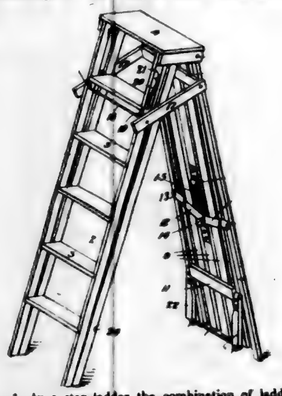
11. The combination, with a reciprocating motor, a motor-controller, an energy-storing actuating device for operating the motor-controller, adapted to be released by a suitable controlling device, and means for storing up energy in said actuating device, of a controlling device provided with an automatically-operated lock for preventing its operation at intervals, said controlling device being adapted to release said actuating device, and means operated by the motor, for operating the lock so as to prevent the operation of said controlling device while the motor is operating.

12. In a damper-operating apparatus, the combination with a motor and a motor-controller, of a spring, an arm connected with the motor-controller and engaging one end or the other of said spring according to the direction in which the motor-controller is to be operated, tripping devices adapted to hold said arm stationary while the spring is being wound up, a spring-winding member mechanically connected with the motor and arranged to wind the spring in one direction or the other according to the direction in which the motor-controller is to be operated, and means for operating the said tripping devices to release said arm.

13. In a damper-operating apparatus, the combination, with a motor, a motor-controller, a spring, an arm connected with the motor-controller and revolubly mounted and arranged to engage one end of the spring or the other, according to the direction in which the spring is to be wound, and tripping-triggers, one adapted to hold said arm against motion in one direction and the other to hold it against motion in the opposite direction, of a spring-winding member mechanically connected with the motor and adapted to wind said spring in one direction or the other according to the direction in which the motor-controller is to be operated, and a cam for operating said triggers and releasing said arm.

14. In a damper-operating apparatus, the combination, with a motor, a motor-controller, an energy-storing controlling device for operating the motor-controller, tripping devices controlling the operation of said energy-storing device, and means operated by the motor for storing energy in such energy-storing device as the motor operates, of an actuating member for actuating said tripping devices, having notches, a locking-pawl adapted to engage said notches and hold said actuating member stationary while energy is being stored, and means for releasing said actuating member when full power has been stored.

708,290. COMBINATION STEP-LADDER AND BENCH. JOHN T. WEITZ, Pittsburg, Pa. Filed May 13, 1901. Serial No. 59,986. (No model.)



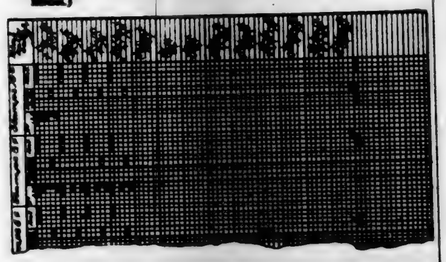
Claim.—1. In a step-ladder the combination of ladder members provided with steps and a top, back supporting-legs therefor pivotally connected to the framework of the ladder, closely-assembled slat members, a double-sided brace pivotally connected with the supporting-leg structure provided with a cross-bar and extended lips, adapted to engage retaining-recesses in the ladder members, and means for distending and adjusting the supporting-legs.

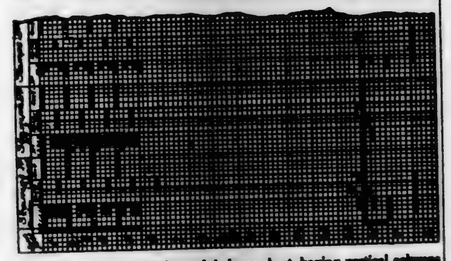
2. In a step-ladder the combination of ladder members provided with steps and a top, back supporting-legs therefor pivotally connected with the framework of the ladder, a double-sided brace pivotally connected with the supporting-leg structure provided with a cross-bar adapted to engage the retaining-recesses in the ladder members, a spring-retaining device adapted to hold such brace members in a raised position and means for distending and adjusting the supporting-legs.

3. In a step-ladder, the combination of ladder members provided with steps, a top, and brace-retaining notches and spring devices, back supporting-legs pivotally connected with the ladder-framework, brace members pivotally connected with the supporting-leg structure and adapted to engage said retaining-notches and spring devices, longitudinal slat members closely assembled with the supporting-legs so as to constitute a bench, and supporting-braces therefor adapted to rest upon the ladder members.

4. In a step-ladder the combination of ladder members provided with steps, a top, and brace-retaining notches and springs, back supporting-legs pivotally connected with the ladder-framework, brace members pivotally connected with the supporting-leg structure, and adapted to engage the retaining-notches and spring devices of the ladder structure, longitudinal slat members closely assembled with the supporting-legs, so as to constitute a bench, and supporting-braces therefor adapted to rest upon the ladder members, and means for distending and adjusting the supporting-legs with relation to the bench-slats.

708,291. INVOICE AND BALANCE SHEET. BENJAMIN A. ALLISON, McPherson, Kans. Filed July 30, 1901. Serial No. 70,107. (No model.)





Claim.—1. An invoice and balance sheet having vertical columns provided with headings for designating kinds of goods or stock, and having the vertical columns subdivided into other vertical columns having headings to indicate quantity of goods on sale, the total value of goods disposed of daily and the total value of the goods on hand at the close of each day's business, and having the series of vertical columns intersected by horizontal lines corresponding to the days of the month and having classifying-spaces for the goods handled on each day of the month, substantially as specified.

2. An invoice and balance sheet having vertical columns provided with headings for designating kinds of goods or stock, and having the vertical columns subdivided into other vertical columns having headings to indicate quantity of goods on sale, the total value of goods disposed of daily and the total value of the goods on hand at the close of each day's business, and having the series of vertical columns intersected by horizontal lines corresponding to the days of the month and having classifying-spaces for the goods handled on each day of the month, and a vertical total daily-sales column intersecting the horizontal spaces corresponding to the days of the month for summarizing the daily sales of all kinds of goods, substantially as described.

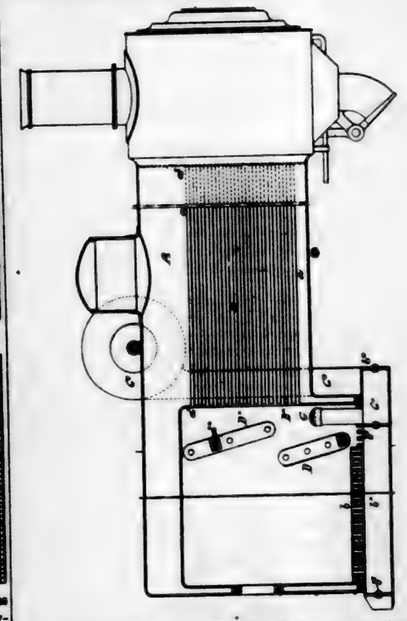
708,292. LOCOMOTIVE. LEONARD ATWOOD, Philadelphia, Pa. Filed Aug. 3, 1901. Serial No. 70,882. (No model.)

Claim.—1. The combination in a boiler, of a fire-box, a tube-sheet and tubes, a pivoted bridge-wall within the fire-box some distance from the tube-sheet and forming a combustion-chamber, a grate with external means for adjusting the bridge-wall to increase or diminish the size of the combustion-chamber, substantially as described.

2. The combination in a boiler, of a fire-box, a tube-sheet, and tubes, a grate, a bridge-wall within the fire-box some distance from the tube-sheet and forming a combustion-chamber, a pivoted deflector above the bridge-wall, with external means for adjusting the deflector to increase or diminish the size of the combustion-chamber and the passage leading thereto from the fire-chamber, substantially as described.

3. The combination in a boiler, of a fire-box, a grate, a pivoted bridge-wall, a pivoted deflector above the bridge-wall, means exterior of the fire-box for adjusting both the bridge-wall and the deflector, substantially as described.

4. The combination in a locomotive, of a fire-box, tubes leading from the fire-box, a grate, a bridge-wall back of the grate, a deflector above the bridge-wall, both the grate and the deflector being pivoted, with means exterior of the fire-box for turning both the bridge-wall and the deflector on their pivots so as to increase or diminish the passage leading from the fire-box to the tubes or to adjust the parts that access may be had to the tubes, substantially as described.



5. The combination in a boiler, of a fire-box, a grate, detachable bearings in the side walls of the fire-box, a pivot-shaft mounted in said bearings and extending through the fire-box, a deflector so mounted on the shaft that when one of the bearings is detached the shaft can be withdrawn to allow for the removal of the deflector, substantially as described.

6. The combination in a boiler, of a fire-box, a grate, a pivoted bridge-wall, a pivoted deflector above the bridge-wall, shafts on which the said bridge-wall and deflector are mounted, said shafts extending through the side wall of the fire-box and detachable from the said bridge-wall and deflector, substantially as and for the purpose specified.

7. The combination in a locomotive, of the fire-box, a grate, an ash-pit under the grate, tubes leading from the fire-box, a pivoted bridge-wall, a pivoted deflector mounted above the bridge-wall, an air-pipe communicating with the combustion-chamber between the bridge-wall and the tube-sheet, and an air-blast device for forcing air under pressure into the combustion-chamber and under the grate, substantially as described.

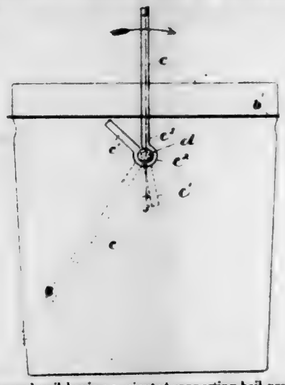
708,293. COVER-LIFTING DEVICE FOR PAILS, &c. ROBERT L. BAKER, Somerville, Mass. Filed July 30, 1901. Serial No. 69,095. (No model.)

Claim.—1. A covered pail having a pivoted bail offset above its pivoted portions to avoid contact with a cover-flange surrounding the pail and provided with cover-lifting fingers located outside the pail and at one side of the axis of the bail and arranged to be moved against the lower edge of the cover-flange in paths which are substantially parallel with the adjacent surfaces of the pail, by a swinging movement of the bail in one direction, and away from the said flange by a swinging movement of the bail in the opposite direction.

2. A covered pail having an outwardly-projecting lip on the flange of its cover, and a bail pivoted to the body of the pail and provided with cover-lifting fingers located outside the pail and at one side of the axis of the bail and arranged to move in paths which are substantially parallel with the adjacent surfaces of the pail and to strike said lip when the bail is moved in one direction from a vertical position.

3. A covered pail, a bail therefor having pivot-engaging eyes offset inwardly from the side portions of the bail, whereby said side portions

are caused to stand out from and clear a lip on the cover of the pail, the said eyes being extended to form lip-engaging fingers located outside the pail and within the said side portions, and arranged to lift the cover when the bail is swung in one direction from a vertical position, said fingers moving in paths that are substantially parallel with the adjacent surfaces of the pail.



4. A covered pail having a pivoted supporting-bail provided with cover-lifting fingers located outside the pail and at one side of the axis of the bail and arranged to be moved toward the cover in paths which are substantially parallel with the adjacent surfaces of the pail by a swinging movement of the bail in one direction, and away from the cover by a swinging movement of the bail in the opposite direction, said fingers being bent inwardly at their upper ends toward the body of the pail and adapted to bear yieldingly thereon.

708,294. CUSPIDOR-RACK. FARLEY F. BALL, Socorro, Col. Filed Apr. 9, 1902. Serial No. 102,064. (No model.)

Claim.—1. The improved rack herein described comprising the base in the form of a ring open at its lower end and flared outwardly toward its upper end, the side frames secured at their lower ends to the base-ring and made in the form of bails having at their upper ends inwardly-projecting portions provided with cross-bars and one of said inwardly-projecting portions being widened adjacent to its cross-bar whereby to permit the adjustment of the other cross-bar within the said widened portion, and the handle having spaced-apart bearings for the said cross-bars and arranged when turned a half-revolution to draw the side frames toward each other or set them apart substantially as set forth.

2. The rack herein described comprising the base, the opposite side frames secured at their lower ends to the base and provided at their upper ends with inwardly-projecting portions and the handle to which the inwardly-projecting portions are jointed at their inner ends at points spaced apart whereby the handle may be turned a half-revolution to adjust the side frames toward or from each other at their upper ends, substantially as set forth.

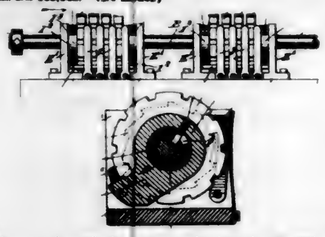
3. The combination in a rack with the base, of side frames secured at their lower ends to the base, and a handle to which the upper ends of said frames are jointed at points spaced apart whereby a half-revolution of the handle may operate to adjust the side frames substantially as set forth.

4. The combination in a rack substantially as described with the handle having spaced-apart bearings of the opposite side frames provided at their ends with cross-bars journaled in said bearings and one of said frames being widened adjacent to its cross-bar, substantially as set forth.

5. A rack having the base composed of an integral or unbroken ring flared upwardly and open at its bottom, the side frames secured at their lower ends to the said base, and the handle connected with the upper ends of the side frames, substantially as set forth.

6. A cuspidor-rack comprising an annular unbroken base, the opposite side frames secured at their lower ends to and connected at such ends by the base, and the handle connecting the upper ends of the side frames, substantially as set forth.

708,295. CONSECUTIVE-NUMBERING APPARATUS. OSWALD G. BARTHEL, Brooklyn, N. Y., assignor to the New York Stencil Works, New York, N. Y., a Corporation of New York. Filed May 24, 1902. Serial No. 108,802. (No model.)



Claim.—1. A numbering apparatus having a longitudinally-grooved shaft, a casing, a sleeve fitted on the shaft and extending through and secured at both ends to the casing, numbering-wheels all mounted loosely on the sleeve, a pawl-frame hung on the sleeve and having an interlocking connection with the grooved shaft to be actuated thereby, and pawls carried by said pawl-frame.

2. A numbering apparatus having a grooved rock-shaft, a double-armed casing, a sleeve secured at its ends to the arms of the casing and fitted loosely on the shaft, a pawl-frame hung loosely on the sleeve and provided with projections which extend into the groove of the shaft, numbering-wheels all mounted loosely on the sleeve, and pawls carried by the pawl-frame; said sleeve and the casing with the connected parts being shiftable endwise on the shaft and the projections of the pawl-frame being slidable in the groove of said shaft.

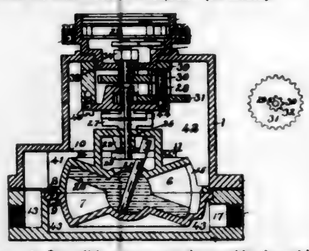
3. A numbering apparatus, having a casing, a sleeve fixed therein and provided with a transverse slot, a numbering-wheel mounted to turn loosely on the said sleeve, a pawl for driving the numbering-wheel, mounted to rock on the sleeve, a pin extending from the pawl through the said slot, and a rock-shaft extending in the sleeve and engaged by the said pin, as set forth.

4. A numbering apparatus, having a casing, a sleeve fixed therein and having a transverse slot, a numbering-wheel mounted to turn loosely on the sleeve, a pawl for driving the numbering-wheel, mounted to rock on the said sleeve, a pin extending inwardly from the pawl through the said slot, and a rock-shaft extending in the sleeve and having a longitudinal keyway for engagement by the inner end of the said pin, as set forth.

5. A numbering apparatus having a longitudinally-grooved shaft, and a plurality of numbering devices each being shiftable lengthwise of the shaft and operable therefrom, each numbering device having a casing, a slotted sleeve secured at both ends to the casing and fitted loosely on the shaft, a pawl-frame hung on the sleeve and provided with projections which pass through the slots in the sleeve and enter the groove of the shaft, numbering-wheels on the sleeve, and pawls on the pawl-carrier.

6. A numbering apparatus, comprising a rock-shaft, a plurality of numbering devices held adjustably on the said rock-shaft and each comprising a casing, a fixed sleeve in the casing, through which extends the rock-shaft, a numbering-wheel mounted to turn loosely on the sleeve, a pawl fulcrumed on the sleeve, and a pin extending through a slot in the sleeve to engage a longitudinal keyway in the said shaft, as set forth.

708,296. WATER-METER. GEORGE B. BARRETT, Buffalo, N. Y. Filed Feb. 14, 1902. Serial No. 94,141. (No model.)



Claim.—1. In a disk water-meter the combination with an inner disk-chamber and an outer case, a gravel-chamber communicating with the inlet-opening of the outside case and a receiving-chamber communicating with the inlet-port of the disk-chamber, of a narrow slot extending along the top edge of the disk-chamber and connecting the gravel-chamber and receiving-chamber, substantially as and for the purpose described.

2. In a disk water-meter the combination with an inner disk-chamber and its projecting flanges of an outer surrounding case so formed as to divide the space above said flanges between the outer wall of the disk-chamber and the inner wall of the outside case into two communicating compartments both adjacent to the disk-chamber substantially as and for the purpose described.

3. In a disk water-meter the combination with an inner disk-chamber and its projecting flanges of an outer surrounding case so formed as to divide the space between the outer wall of the disk-chamber and the inner wall of the outer case into three compartments adjacent to the disk-chamber two compartments being above said flanges and one compartment below said flanges, substantially as and for the purpose described.

4. In a disk water-meter an inner removable disk-chamber composed of two equal sections with inlet and outlet ports having the opposite part of each port formed unequally in the spherical side walls of both sections substantially as and for the purpose described.

5. In a disk water-meter the combination with a disk and its disk-chamber of an inlet-port and an outlet-port formed in the spherical side wall of said disk-chamber with one edge each that does and one edge that does not alternately overlap the edge of said disk when the edge of said disk between said ports is at its points of greatest oscillation, substantially as and for the purpose described.

6. In a disk water-meter the combination with the disk-chamber of an inlet-port and an outlet-port formed in the spherical side wall of said disk-chamber each with one diagonally opposite edge cut away so as to afford the water easy access to and egress from said measuring-chamber.

7. In a disk water-meter the combination with the disk-chamber, the disk and its spindle, a recess formed by walls integral with the end walls of said disk-chambers and into which recess said disk-spindle projects, of an opening into said recess through the side of said integral walls for the purpose of observing said spindle.

8. In a water-meter, the combination with an intermediate toothed wheel and notches formed in the edge of a central hole in said wheel, a pinion with teeth adapted to fit said notches and prevent said pinion turning in said wheel when the two are permanently joined, of shoulders formed in said pinion-teeth, substantially as and for the purpose described.

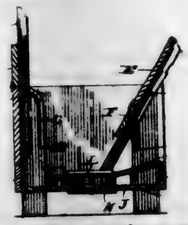
9. In a water-meter, the combination with a hollow pinion and shouldered toothed projections formed on said pinion of a gear-wheel and notches formed in the edge of a central hole formed in said wheel adapted to fit said projections and prevent said pinion turning in said wheel when the two are permanently joined, substantially as and for the purpose described.

10. In a water-meter, the combination with a shaft, a hollow pinion turning loosely on said shaft and shouldered teeth formed on said pinion, of notches formed on the edge of the central hole of a gear-wheel mounted on said shouldered pinion-teeth, substantially as and for the purpose described.

11. In a water-meter, the combination with a supporting-piece for the indicator and stuffing-box and a threaded projection on the lower end of the supporting-piece extending through the outer wall of the meter-case of a clamping-nut located on the inside of the meter-case and mounted onto the projection of said supporting-piece, substantially as and for the purpose described.

12. In a water-meter, the combination with a supporting-piece for the indicator and stuffing-box and a clamping-nut therefor located in the interior of said meter, of an interior intermediate gear-frame mounted on said clamping-nut, substantially as and for the purpose described.

708,297. COMBINATION SHEEP FEEDING RACK AND SHEARING TABLE. VIC RADEBAUGH, Marysville, Ohio. Filed Mar. 20, 1899. Serial No. 711,085. (No model.)



Claim.—In a sheep-feeding rack, a frame supporting a bed, a central longitudinal grain-receptacle mounted upon the said bed having oppositely-disposed longitudinal feeding-slots through the sides thereof, a trough upon each side of the grain-receptacle into which the feeding-slots open, leaves having series of bars arranged thereupon curved slots in each end of the frame, the bars upon the respective ends of the leaves being pivotally and adjustably secured in the said slots, dependent leaves hinged to the leaves supported by the bars, and adapted to be folded down upon the bars or back upon the leaves supported thereby, substantially as shown and for the purpose set forth.

708,298. KNIFE FOR MICROTOMES. EDWARD BAUSCH, Rochester, N. Y., assignor to Bausch & Lomb Optical Company, Rochester, N. Y., a Corporation of New York. Filed June 14, 1901. Serial No. 64,567. (No model.)

Claim.—1. The combination with a knife-blade, a holder therefor extending over one side of the blade and having the recesses open at their lower sides in which the ends of the blade rest, of the fastening devices extending through the holder and engaging the ends of the blade.

2. The combination with a knife-blade, a holder therefor extending over one side of the blade and having the recesses therein open at their lower sides adapted to receive the ends of the blade, of the bolts extending through the holder having the heads engaging the ends of the blade to prevent its removal.

3. The combination with a knife-blade, of a holder extending above one side of the latter, a portion of said holder being out of contact therewith and engaging the ends of the blade only, and adjustable fastening devices securing the blade at its ends and operable from the upper side of the holder.

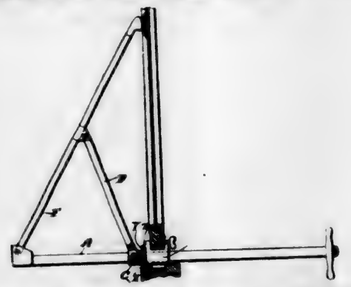
4. The combination with a knife-blade, angular in cross-section, of a holder extending over one side of the blade having recesses provided with sloping faces against which the ends of the blade are secured, stops for limiting the rearward movement of the blade, and clamping devices engaging the blade and operative from the opposite side of the holder.

5. The combination with a knife-blade, angular in cross-section, of a holder extending above one side of the knife, a portion of said holder being out of contact therewith, and having the recesses adapted to receive the ends of the blade provided with the sloping sides against which the blade is secured, stops limiting the inward movement of the blade on said surfaces, and bolts adjustable in the support having the heads engaging the blade.

6. The combination with the arched knife-holder, of a cutting-blade extending beneath the arch and engaging the holder at its ends only, clamps engaging the ends of the blade and means for operating said clamps simultaneously.

7. The combination with the arched knife-holder, of a cutting-blade extending beneath the arch and engaging the holder at its ends only, the bolts having the heads engaging the knife ends, the lever-plate pivoted on the holder and engaging the upper ends of the bolts and means for operating said lever-plate.

708,299. WINDOW-CLEANER. HOYES B. BEELER, Chicago, Ill. Filed Feb. 15, 1902. Serial No. 94,158. (No model.)



Claim.—1. A window-cleaner comprising a rotatable, longitudinally-movable shaft, means to hold the same to a window-frame, a lever having a cleaning device at one end and hinged at its other end to said shaft, and a fulcrum-arm supported upon the window-frame and pivoted to the lever.

2. In a window-cleaner, the combination of a block secured to a window-frame, a shaft carried thereby and capable of rotary and longitudinal movement, an arm pivotally connected to the block, and a lever attached to the outer end of the shaft and fulcrumed on the arm.

3. In a window-cleaner, in combination, a block secured to a win-

dow-frame, a collar rotatably attached thereto, a shaft extending through the block and collar and movable rotatively and longitudinally therein, a lever attached to the shaft carrying a cleaning device, and a fulcrum-arm for the lever pivoted to the collar.

708,800. COMBINED GRAIN-DOOR AND LOADING AND UNLOADING PLATFORM FOR BOX-CARS. JACOB S. BENDER, Kansas City, Mo. Filed Jan. 3, 1902. Serial No. 88,293. (No model.)
